Unpurified or *brown sugar* is in the form of a coarse powder, more or less moist and sticky, consisting of shining crystalline grains, intermixed with lumps, having a brownish-yellow colour more or less deep, a sweet, cloying taste, and a heavy and peculiar smell. It differs very much in quality. The best sort is nearly dry, in large sparkling grains of a clear yellow colour, and possesses much less smell than the inferior kinds. It consists of the pure crystallizable sugar, combined with variable quantities of colouring and extractive matter.

Molasses is a black ropy liquid of a peculiar odour, and a sweet empyreumatic taste. When fermented it forms rum. It consists principally of uncrystallizable sugar.

Composition. Pure sugar from the cane consists, according to Prout, of one equiv. of hydrogen 1, one of carbon 6, and one of oxygen 8=15. The theory of its conversion, during the vinous fermentation, into carbonic acid and alcohol, has been explained under another head. (See *Alcohol.*) According to Berzelius, however, cane sugar is a hydrate, consisting of one equiv. of dry sugar and one of water. He founds this opinion on the fact that his analysis of dry saccharate of lead, gives for the combined sugar the same elements as for cane sugar, *minus* one equiv. of oxygen and one equiv. of hydrogen, that is, one equiv. of water.

Pharmaceutical Uses, &c. The uses of sugar as an aliment and condiment are numerous. It is nutritious, but, judging from the results of the experiments of Magendie, not capable of supporting life when taken exclusively as aliment, on account of the absence of nitrogen in its composition. It is a powerful antiseptic, and is beginning to be used for preserving meat and fish; for which purpose it possesses the advantage of acting in a much less quantity than is requisite of common salt, and of not altering the taste, nor impairing the nutritious qualities of the aliment. It was formerly supposed to be an antidote to the poisonous effects of copper, but this proves to be a mistake. (See *Cuprum.*)

In pharmacy, *sugar* is employed to render oils miscible with water, to cover the taste of medicines, to give them consistency, and to preserve them from change. Accordingly it enters into the composition of several infusions and mixtures, and of nearly all the syrups, confections, and troches. *Brown sugar* is used to form the London and Dublin compound pills of iron, and the Dublin and Edinburgh infusion of senna with tamarinds; and *molasses*, in preparing the Edinbrugh syrup of senna, and the Dublin compound pills of calomel, of colocynth, and of galbanum, and the electuary of senna. In the United States Pharmacopœia, in which the two latter forms of sugar are not officinal, their place is usually supplied by the use of syrup. B.

SAGAPENUM. *Lond., Ed., Dub.*

Sagapenum.

"*Plantæ nondum descriptæ Gummi-resina.*" *Lond.*

Sagapenum, *Fr.;* Sagapen, *Germ.;* Sagapeno, *Ital., Span.;* Sugbeenuj, *Arab.*

All that is known in relation to the source of this gum-resin, is that it is the concrete juice of a plant, probably belonging to the family of the Umbelliferæ, growing in Persia. The plant is conjectured to be a species of Ferula, and Willdenow supposes it to be the *F. Persica*, but without sufficient evidence. The drug is brought from Alexandria, Smyrna, and other ports of the Levant.

It is in irregular masses composed of soft agglutinated fragments, slightly translucent, of a brownish-yellow, olive, or reddish-yellow colour externally, paler internally, brittle, of a consistence somewhat resembling that of wax, and often mixed with impurities, especially with seeds more or less entire. It has an alliaceous odour, less disagreeable than that of assafetida, and a hot nauseous bitterish taste. It softens and becomes tenacious by the heat of the hand. The effect of time and exposure is to harden and render it darker. It is inflammable, burning with a white flame and much smoke, and leaving a light spongy charcoal. Pure alcohol and water dissolve it partially, diluted alcohol almost entirely. Distilled with water it affords a small quantity of volatile oil; and the water is strongly impregnated with its flavour. According to Pelletier, it contains in 100 parts 54.26 of resin, 31.94 of gum, 1.0 of bassorin, 0.60 of a peculiar substance, 0.40 of acidulous malate of lime, and 11.80 of volatile oil including loss. Brandes found 3.73 per cent of volatile oil. This is of a pale yellow colour, very fluid, lighter than water, and of a very disagreeable alliaceous odour.

Medical Properties and Uses. Sagapenum is a moderate stimulant, similar to assafetida in its properties, but much inferior, and usually considered as holding a middle station between that gum-resin and galbanum. It has been given as an emmenagogue and antispasmodic in amenorrhœa, hysteria, chlorosis, &c., but is now seldom used. The ancients were acquainted with it; and Dioscorides speaks of it as being derived from Media. The dose is from ten to thirty grains, and may be administered in pill or emulsion. Sagapenum is also considered discutient, and has been occasionally applied externally, in the form of a plaster, to indolent tumours.

SAGO. *U.S.*

Sago.

"Cycas circinalis et Sagus Rumphii. Medulla præparata. *The prepared pith.*" *U.S.*

Sagou, *Fr.;* Sago, *Germ., Ital.;* Sagu, *Span.*

Numerous trees inhabiting the islands and coasts of the Indian Ocean, contain a farinaceous pith which is applied to the purposes of nutriment by the natives. Such are the *Sagus Rumphii*, *Sagus Ruffia*, and *Phœnix farinifera*, belonging to the family of the *Palms;* and the *Cycas circinalis*, *Cycas revoluta*, and *Zamia lanuginosa* belonging to the *Cycadeæ.* Of these the *Cycas circinalis*, *Cycas revoluta*, and *Sagus Rumphii*, have been severally indicated as the source of sago; and it is possible that they may all afford this peculiar form of farinaceous matter; but we are assured by Crawford, in his History of the Indian Archipelago, that the sago of commerce is derived exclusively from the *Metroxylon Sagu*, identical with the *Sagus Rumphii;* and this is at present the generally received opinion.

SAGUS. *Sex. Syst.* Monœcia Hexandria.—*Nat. Ord.* Palmæ.

Gen. Ch. Common spathe one-valved. *Spadix* branched. MALE. *Calyx* three-leaved. *Corolla* none. *Filaments* dilated. FEMALE. *Calyx* three-leaved, with two of the leaflets bifid. *Corolla* none. *Style* very short. *Stigma* simple. *Nut* tessellated-imbricated, one-seeded. *Willd.*

Sagus Rumphii. Willd. *Sp. Plant.* iv. 404; Loudon's *Encyc. of Plants*, p. 789. The *Sago palm* is one of the smallest trees of the family to which it belongs. Its extreme height seldom exceeds thirty feet. The trunk is proportionably very thick, quite erect, cylindrical, covered with the remains of the old leafstalks, and surrounded by a beautiful crown of foliage, consisting of numerous, very large, pinnate leaves, extending in every direction from the summit, and curving gracefully downwards. From the basis of the leaves proceed long divided and sub-divided flower and fruit-bearing spadices, the branches of which are smooth. The fruit is a roundish nut, covered with a chequered imbricated coat, and containing a single seed.

The tree is a native of the East India islands, growing abundantly in the Moluccas, Borneo, Celebes, and a part of New Guinea. It flourishes best in low and moist situations. Before attaining maturity, the stem consists of a shell usually about two inches thick, filled with an enormous volume of spongy medullary matter like that of elder. This is gradually absorbed after the appearance of fruit, and the stem ultimately becomes hollow. The greatest age of the tree is not more than thirty years. At the proper period of its growth, when the medullary matter is fully developed, and has not yet begun to diminish, the tree is felled, and the trunk cut into billets six or seven feet long, which are split in order to facilitate the extraction of the pith. This is obtained in the state of a coarse powder, which is mixed with water in a trough, having a sieve at the end. The water loaded with farina, passes through the sieve, and is received in convenient vessels, where it is allowed to stand till the insoluble matter has subsided. It is then strained off; and the farina which is left may be dried into a kind of meal, or moulded into whatever shape may be desired. For the consumption of the natives it is usually formed into cakes of various sizes, which are dried, and extensively sold in the islands. The commercial sago is prepared by forming the meal into a paste with water, and rubbing it into grains. It is produced in the greatest abundance in the Moluccas, but of the finest quality on the eastern coast of Sumatra. The Chinese of Malacca refine it so as to give the grains a fine pearly lustre. In this state it is called *pearl sago*, and is in great repute. It is said that not less than five or six hundred pounds of sago are procured from a single tree. (*Crawford.*)

Pearl sago is that which is now generally used. It is in small grains, about the size of a pin's head, hard, whitish or of a light brown colour, in some instances translucent, inodorous, and with little taste.

Common sago is in larger grains, of more unequal size, of a duller aspect, and frequently mixed with more or less of a dirty looking powder.

Sago is insoluble in cold water, but by long boiling unites with that liquid, becoming at first soft and transparent, and ultimately forming a gelatinous solution. Chemically considered, it has the characters of starch.

It is used exclusively as an article of diet, having no medicinal qualities which adapt it to the treatment of disease. Being nutritive, easily digestible, and wholly destitute of irritating properties, it is frequently employed in febrile cases, and in convalescence from acute disorders, in the place of richer and less innocent food. It is given in the liquid state, and in its preparation care should be taken to boil it long in water, and stir it diligently, in order that the grains may be thoroughly dissolved. Should any portion remain undissolved, it should be separated by straining, as it might offend a delicate stomach. A table-spoonful to the pint of water is sufficient for ordinary purposes. The solution may be seasoned with sugar and nutmeg, or with other spices where these are not contraindicated. W.

SALIX. *U.S. Secondary.*

Willow.

"Salix alba et aliæ. Cortex. *The bark.*"

Off. Syn. SALICIS CORTEX. Salix Caprea. Cortex. *Lond.;* SALICIS CAPREÆ CORTEX. *Ed.;* SALIX ALBA. SALIX FRAGILIS SALIX CAPREA. Cortex. *Dub.*

Ecorce de saule, *Fr.;* Weidenrinde, *Germ.;* Corteccia di salcio, *Ital.;* Corteza de sauc *Span.*

Salix. *Sex.Syst.* Diœcia Diandria.—*Nat. Ord.* Amentaceæ, *Juss.;* Salicineæ, *Richard, Lindley.*

Gen.Ch. Male. *Amentum* cylindrical. *Calyx* a scale. *Corolla* none. *Glands* of the base nectariferous. Female. *Amentum* cylindrical. *Calyx* a scale. *Corolla* none. *Style* two-cleft. *Capsule* one-celled, two-valved. *Seeds* downy. *Willd.*

This is a very extensive genus, comprising, according to Nuttall, not less than one hundred and thirty species, which, with very few exceptions, are natives of Europe and of the northern and temperate parts of North America. Though they are all probably possessed of similar medical properties, only three have been admitted to the rank of officinal plants by the British Colleges; viz. *S. alba*, *S. caprea*, and *S. fragilis*. Of these species, the *Salix alba* is the only one which has been introduced into this country, and is expressly recognised in the last edition of our Pharmacopœia. Many native species are in all probability equally active; but they have not been sufficiently tried in regular practice to admit of a positive decision in relation to them. The younger Michaux speaks of the *S. nigra* or *black willow*, as affording in its root a strong bitter used in the country as a preventive and cure of intermittents. In consequence of the pliability of the young branches or twigs, the willow is admirably adapted for the manufacture of baskets and other kinds of wicker-work, and several species, as well native as introduced, are employed for this purpose in the United States. The *S. Babylonica* or weeping willow is a favourite ornamental tree.

Salix alba. Willd. *Sp. Plant.* iv. 710; Smith, *Flor. Brit.* 1071. The common European or white willow is a tree twenty-five or thirty feet in height, with numerous round spreading branches, the younger of which are silky. The bark of the trunk is cracked and brown, that of the smaller branches smooth and greenish. The leaves are alternate, upon short petioles, lanceolate, pointed, acutely serrate with the lower serratures glandular, pubescent on both sides, and silky beneath. There are no stipules. The flowers appear at the same time with the leaves. The *amenta* are terminal, cylindrical, and elongated, with elliptical, lanceolate, brown, pubescent scales. The stamens are two in number, yellow, and somewhat longer than the scales; the style is short; the stigmas two-parted and thick. The capsule is nearly sessile, ovate, and smooth.

The white willow has been introduced into this country from Europe, and is now very common. It flowers in April and May; and the bark is easily separable throughout the summer.

That obtained from the branches rolls up when dried into the form of a quill, has a brown epidermis, is flexible, fibrous, and of difficult pulverization. Willow bark has a feebly aromatic odour, and a peculiar bitter astringent taste. It yields its active properties to water, with which it forms a reddish-brown decoction. Pelletier and Caventou found among its ingredients, tannin, resin, a yellow colouring matter, gum, and an acid. The proportion of tannin is so considerable that the bark has been used for tanning eather. A crystalline principle has recently been obtained from it, which, having the medical virtues of the willow, has received the name of *salicin.* When pure, it is in white, shining, slender crystals, very bitter to the taste, with the peculiar flavour of the bark. It is soluble in cold water, much more o in boiling water, soluble in alcohol, and insoluble in ether and the oil of urpentine. Uniting neither with acids nor salifiable bases, and containing no itrogen, it has no claims to rank among the vegetable alkalies. Concentrated ulphuric acid decomposes it, receiving from it an intense and permanent right red colour. The diluted acids dissolve it without change. The honour of its discovery is claimed by Buchner of Germany, and Fontana and Rigatelli of Italy; but M. Leroux of France deserves the credit of having first accurately investigated its properties. M. Braconnot procures it by adding subacetate of lead to a decoction of the bark, precipitating the excess of lead by sulphuric acid, evaporating the colourless liquid which remains, adding near the end of the process a little animal charcoal previously washed, and filtering the liquor while hot. Upon cooling it deposites the salicin in a crystalline form. (*Journ. de Chimie Medicale, Janv.* 1831.) Messrs. Fisher and Tyson of Baltimore recommend the following process, which they have tried with success. Willow bark is boiled with caustic lime in water, the decoction filtered, and sulphate of zinc added so long as it produces a precipitate. The liquid having been again filtered, is evaporated to the consistence of an extract, and the residue treated with alcohol. The tincture thus obtained, if carefully evaporated, yields crystals of salicin, which may be purified by washing with a saturated solution of the same principle in cold water. (*Journ. of the Phil. Col. Pharm.* iii. 214.) The *Salix helix* is the species which in France has been found most productive of salicin; but the *S. alba* and others also afford it. *M. Braconnot* has obtained it from various species of Populus, particularly the *P. tremula* or European aspen.

Medical Properties and Uses. The bark of the willow is tonic and astringent; and has been employed as a substitute for Peruvian bark, particularly in intermittent fever. It has recently attracted much attention from the asserted efficacy of salicin in the cure of this complaint. There seems to be no room to doubt, from the testimony of numerous practitioners in France, Italy, and Germany, that this principle has the property of arresting intermittents; though the ascription to it of equal efficacy with the sulphate of quinia was certainly premature. The bark may be employed in substance or decoction, in the same doses and with the same mode of preparation as cinchona. The dose of salicin is from two to eight grains, to be so repeated that from twenty to forty grains may be taken daily, or in the interval between the paroxysms of an intermittent. Magendie has seen fevers cut short in one day by three doses of six grains each. The decoction of willow has been found beneficial as an external application in foul and indolent ulcers.

SALVIÆ OFFICINALIS FOLIA. *Ed.*

Leaves of Sage.

Sauge, *Fr.;* Salbey, *Germ.;* Salvia, *Ital., Span.*

Salvia. *Sex. Syst.* Diandria Monogynia.—*Nat. Ord.* Labiatæ.

Gen. Ch. Corolla unequal. *Filaments* affixed transversely to a pedicel. *Willd.*

Salvia officinalis. Willd. *Sp. Plant.* i. 129; Woodv. *Med. Bot.* p. 35 t. 127. The common garden sage is a perennial plant, about two feet hig with a quadrangular, pubescent, branching, shrubby stem, furnished wi opposite, petiolate, ovate lanceolate, crenulate, wrinkled leaves, of a grayis green colour, sometimes tinged with red or purple. The flowers are blu variegated with white and purple; and are disposed on long terminal spik in distant whorls, each composed of few flowers, and accompanied wi ovate, acute, deciduous bractes. The calyx is tubular and striated, wi two lips, of which the upper has three acute teeth, the under two. T corolla is tubular, bilabiate, ringent, with the upper lip concave, the lower divided into three rounded lobes, of which the middle is the largest. The filaments are supported upon short pedicels, to which they are affixed transversely at their middle.

Sage grows spontaneously in the South of Europe, and is cultivated abundantly in our gardens. There are several varieties, differing in the size and colour of their flowers, but all possessed of the same medical properties. The flowering period is in June, at which time the plant should be cut, and dried in a shady place. The leaves are the officinal portion.

Both these and the flowering summits have a strong, fragrant odour, and a warm, bitterish, aromatic, somewhat astringent taste. They abound in a volatile oil, which may be obtained separate by distillation with water, and contains a considerable proportion of camphor. Sulphate of iron strikes a black colour with their infusion.

Medical Properties and Uses. Sage unites a slight degree of tonic power and astringency with the properties common to the aromatics. By the ancients it was very highly esteemed; but it is at present little used internally, except as a condiment. In the state of infusion it may be given in debilitated conditions of the stomach attended with flatulence, and is said to have been useful in checking the exhausting sweats of hectic fever. But its most usual application is as a gargle in inflammation of the throat and relaxation of the uvula. For this purpose it is usually employed in infusion with honey and alum, or vinegar. From twenty to thirty grains of the powdered leaves may be given for a dose. The infusion is prepared by macerating an ounce of the leaves in a pint of boiling water, of which two fluidounces may be administered at once. When intended to be used merely as a pleasant drink in febrile complaints, or to allay nausea, the maceration should continue but a very short time, so that all the bitterness of the leaves may not be extracted.

Two other species of Salvia—the *S. pratensis* and *S. Sclarea*—are ranked among the officinal plants in Europe. The latter, which is commonly called *clarry*, has been introduced into our gardens. Their medical properties are essentially the same as those of the common sage; but they are less agreeable, and are not much used. In Europe, the leaves of the *S. Sclarea* are said to be introduced into wine in order to impart to it a muscadel taste.

W.

SAMBUCUS. *U.S. Secondary.*

Elder Berries.

"Sambucus Canadensis. Baccæ. *The berries.*" *U. S.*

Sambucus. *Sex. Syst.* Pentandria Trigynia.—*Nat. Ord.* Caprifoliaceæ.

Gen. Ch. *Calyx* five-parted. *Corolla* five-cleft. *Berry* three-seeded. *Willd.*

Sambucus Canadensis. Willd. *Sp. Plant.* i. 1494. Our indigenous *common elder* is a shrub from six to ten feet high, with a branching stem, which is covered with a rough gray bark, and contains a large spongy pith. The small branches and the leafstalks are very smooth. The leaves are opposite, pinnate, sometimes bipinnate, and composed usually of three or four pairs of oblong oval, acuminate, smooth, shining, deep-green leaflets, the midribs of which are somewhat pubescent. The flowers are small, white, and disposed in loose cymes, having about five divisions. The berries are small, globular, and when ripe of a deep purple colour.

The shrub grows in low moist grounds, along fences, and on the borders of small streams, in all parts of the United States, from Canada to Carolina. It flowers from May to July, and ripens its berries early in the autumn. These are the only officinal portion, though other parts of the plant are employed in domestic practice, and have been found to answer the same purposes with the corresponding parts of the European elder, to which this species bears a very close affinity. (See *Sambuci Nigræ Flores, &c.*) W.

SAMBUCI NIGRÆ FLORES, BACCÆ, CORTEX. *Ed.*

Flowers, Berries, and Bark of Common European Elder.

Off. Syn. SAMBUCI FLORES. *Lond.;* SAMBUCUS NIGRA. Flores. Baccæ. Cortex interior. *Dub.*

Sureau, *Fr.;* Hollunder, *Germ.;* Sambuco, *Ital.;* Sauco, *Span.*

Sambucus. See SAMBUCUS.

Sambucus nigra. Willd. *Sp. Plant.* i. 1495; Woodv. *Med. Bot.* p. 596. t. 211. The common elder of Europe differs from the American most obviously in its size, which approaches to that of a small tree. The stem is much branched towards the top, and has a rough whitish bark. The leaves are pinnate, consisting usually of five oval, pointed, serrate leaflets, four of which are in opposite pairs, and the fifth terminal. The flowers are small, whitish, and in five-parted cymes. The berries are globular, and of a blackish-purple colour when ripe.

The flowers have a peculiar rather unpleasant odour, which is strong in their recent state, but becomes feeble by drying. Their taste is bitterish. They yield their active properties to water by infusion, and when distilled give over a small proportion of volatile oil, which on cooling assumes a butyraceous consistence. Water distilled from them contains an appreciable portion of ammonia. The berries are nearly inodorous, but have a sweetish acidulous taste, dependent on the saccharine matter and malic acid which they contain. Their expressed juice is susceptible of fermentation, and forms a vinous liquor used in the North of Europe. It is coloured violet by alkalies, and bright red by acids; and the colouring matter is precipitated blue by acetate of lead. The inner bark is without smell; its taste is at first sweetish, afterwards slightly bitter, acrid, and nauseous. Both water and alcohol extract its virtues, which are said to reside especially in the green layer between the liber and epidermis.

Medical Properties and Uses. The flowers are gently excitant and sudorific, but are seldom used except externally as a discutient in the form of poultice, fomentation, or ointment. The berries are diaphoretic and aperient; and their inspissated juice has enjoyed some reputation as a remedy in rheumatic, gouty, eruptive, and syphilitic affections. Its dose as an alterative diaphoretic is one or two drachms, as a laxative half an ounce or more. The inner bark is a hydragogue cathartic, acting also as an emetic in large doses. It has been employed in dropsy and as an alterative in various chronic diseases. One ounce may be boiled with two pints of water to a pint, and four fluidounces of the decoction given for a dose It is also sometimes used in vinous infusion. The leaves are not withou activity, and the young leaf-buds are said to be a violent and even unsafe purgative.

SANGUINARIA. *U.S.*

Blood-root.

"Sanguinaria Canadensis. Radix. *The root.*" *U.S.*

SANGUINARIA. *Sex. Syst.* Polyandria Monogynia.—*Nat. Ord.* Papaveraceæ.

Gen. Ch. Calyx two-leaved. *Petals* eight. *Stigma* sessile, two-grooved. *Capsule* superior, oblong, one-celled, two-valved, apex attenuated. *Receptacles* two, filiform, marginal. *Nuttall.*

Sanguinaria Canadensis. Willd. *Sp. Plant.* ii. 1140; Bigelow, *Am. Med. Bot.* i. 75; Barton, *Med. Bot.* i. 31. The *blood-root*, or, as it is sometimes called, *puccoon*, is an herbaceous perennial plant. The root is horizontal, abrupt, often contorted, about as thick as the finger, two or three inches long, fleshy, of a reddish-brown colour on the outside, and brighter red within. It is furnished with numerous slender radicles, and makes offsets from the sides, which succeed the old plant. From the end of the root arise the scape and leafstalks, surrounded by the large sheaths of the bud. These spring up together, the folded leaf enveloping the flower-bud, and rolling back as the latter expands. The leaf, which stands upon a long channeled petiole, is reniform, somewhat heart-shaped, deeply lobed, smooth, yellowish-green on the upper surface, paler or glaucous on the under, and strongly marked by orange-coloured veins. The scape is erect, round and smooth, rising from six inches to a foot in height, and terminating in a single flower. The calyx is two-leaved and deciduous. The petals, varying from seven to fourteen, but usually about eight in number, are spreading, ovate, obtuse, concave, mostly white, but sometimes slightly tinged with rose or purple. The stamens are numerous, with yellow filaments shorter than the corolla, and orange oblong anthers. The germ is oblong and compressed, and supports a sessile, persistent stigma. The capsule is oblong, acute at both ends, two-valved, and contains numerous oval, reddish-brown seeds. The whole plant is pervaded by an orange-coloured sap, which flows from every part when broken; but is of the deepest colour in the root.

The blood-root is one of the earliest and most beautiful spring flowers of North America. It grows abundantly throughout the whole United States, delighting in rich loose soils, and shady situations, and flowering in March and April. After the fall of the flower, the leaves continue to increase in size, and by the middle of summer, have become so large as to give the plant an entirely different aspect. All parts of the plant are active, but the root only is officinal.

This, when dried, is in pieces from one to three inches long, from a quarter to half an inch or more in thickness, flattened, much wrinkled and twisted, often furnished with abrupt offsets and numerous short fibres, of a reddish-brown colour externally, with a spongy uneven fracture, the surface of which is at first bright orange, but becomes of a dull brown by long exposure. The colour of the powder is a brownish orange-red. Sanguinaria has a faint narcotic odour, and a bitterish very acrid taste, the pungency of which remains long in the mouth and fauces. It yields its virtues to water and alcohol. The late Dr. Dana of New York obtained from it a peculiar alkaline principle, denominated by him *sanguinarina*, upon which the acrimony, and perhaps the medical virtues of the root depend. It may be procured, according to Dana, by infusing the finely powdered root in hot water or diluted muriatic or acetic acid, precipitating with water of ammonia, collecting the precipitated matter, boiling it in water with pure animal charcoal, filtering off the water, exposing the residue left upon the filter to the action of alcohol, and finally evaporating the alcoholic solution. (*Ann. Lyc. of Nat. Hist. New York*, ii. 250.) Sanguinarina, thus obtained, is a white pearly substance, of an acrid taste, very sparingly soluble in water, soluble in ether, and very soluble in alcohol. With the acids it forms salts soluble in water, all of which have some shade of red, crimson, or scarlet, and form beautiful red solutions. They are acrid and pungent to the taste, particularly the muriate and acetate. From these facts it would appear, that the red colour and acrid properties of the blood-root may be owing to the presence of some native salt of sanguinarina, which is decomposed by ammonia in the process of separating the vegetable alkali.

The virtues of the root are said to be rapidly deteriorated by time.

Medical Properties and Uses. Sanguinaria is an acrid emetic, with stimulant and narcotic powers. In small doses it excites the stomach, and accelerates the circulation; more largely given, it produces nausea and consequent depression of the pulse; and in the full dose occasions active vomiting. The effects of an overdose are violent emesis, a burning sensation in the stomach, faintness, vertigo, dimness of vision, and alarming prostration. Snuffed up the nostrils it excites much irritation, attended with sneezing. Upon fungous surfaces it acts as an escharotic. It has been given in typhoid pneumonia, catarrh, pertussis, croup, phthisis pulmonalis, rheumatism, jaundice, hydrothorax, and some other affections, either as an emetic, nauseant, or alterative; and its virtues are highly praised by many judicious practitioners.

The dose with a view to its emetic operation is from ten to twenty grains, given in powder or pill. The latter form is preferable in consequence of the great irritation of throat produced by the powder when swallowed. For other purposes, the dose is from one to five grains, repeated more or less frequently according to the effect desired. The medicine is sometimes given in infusion or decoction, in the proportion of half an ounce to the pint. The emetic dose of this preparation is from half a fluidounce to a fluidounce. The tincture is officinal. An infusion in vinegar has been employed advantageously, as a local application, in obstinate cutaneous affections.

PTEROCARPUS. *Sex. Syst.* Diadelphia Decandria.—*Nat. Ord.* Leguminosæ.

Gen. Ch. Calyx five-toothed. *Legume* falcated, leafy, varicose, girted by a wing, not gaping. *Seeds* solitary. *Willd.*

Pterocarpus santalinus. Willd. *Sp. Plant.* iii. 906; Woodv. *Med. Bot.* p. 430. t. 156. This is a large tree with alternate branches, and petiolate ernate leaves, each simple leaf being ovate, blunt, somewhat notched at the apex, entire, veined, smooth on the upper surface, and hoary beneath. The lowers are yellow, in axillary spikes, and have a papilionaceous corolla, of which the *vexillum* is obcordate, erect, somewhat reflexed at the sides, oothed, and waved, the *alæ* spreading with their edges apparently toothed, and the *carina* oblong, short, and somewhat inflated. The tree is a native of ndia, and attains the highest perfection in mountainous districts. Its wood s the true officinal *red saunders,* though there is reason to believe that the product of other trees is sold by the same name.

It comes in squared or angular billets, internally of a blood-red colour, ex-ernally brown from exposure to the air, compact, heavy, and of a fibrous exture. It is kept in the shops in the state of small chips, raspings, or coarse powder.

Red saunders has little smell or taste. It imparts a red colour to alcohol and ether, but not to water; and a test is thus afforded by which it may be listinguished from some other colouring woods. The colouring principle, which has been separated by Pelletier, and called by him *santalin,* is of a esinous character, scarcely soluble in cold water, more so in boiling water, very soluble in alcohol, ether, acetic acid, and alkaline solutions, but slightly n the fixed and volatile oils, with the exception of those of lavender and osemary, which readily dissolve it.

The wood has no medical virtues, and is employed solely for the purpose of imparting colour.

Soaps, in the most extended signification of the term, embrace all those compounds which result from the reaction of oils and fats on salifiable bases. During this reaction, the fatty bodies are said to undergo *saponification*, and are changed into three peculiar acids, the *margaric*, *oleic*, and *stearic*, which unite with the salifiable base, and into a sweet principle called *glycerine*, which remains behind. Soap, under this view of its nature, is really a saline compound, consisting of a mixture, in variable proportions, of the *margarate*, *oleate*, and *stearate* of some base. The glycerine is not saponifiable.

Soaps are arranged in two divisions, the soluble and insoluble. The soluble soaps are those formed with soda, potassa, and ammonia; the insoluble include those generated with other salifiable bases, whether earths or metallic oxides. It is the soluble soaps only which are detergent, and it is to these that the term *soap* is generally applied. On the other hand, the insoluble soaps, though not fit to be used in domestic economy, are some of them employed in pharmacy; as for example, the soap of the oxide of lead, or lead plaster, and the soap of lime. (See *Emplastrum Plumbi* and *Linimentum Calcis.*)

The consistency of the fixed alkaline soaps depends partly on the nature of the oleaginous matter employed, but principally on the alkali present; soda forming a hard, and potassa a soft soap, as correctly stated in the officinal definitions of the British Colleges. This difference depends upon the circumstance, that the stearate, margarate, and oleate of soda are firm and solid; while the corresponding salts of potassa, which are the constituents of soft soap, have a gelatinous consistency. The soap of soda is more or less hard, according as the stearate and margarate, or the oleate predominate in its composition. These variations in its constitution depend upon the nature of the oily matter. It has been explained elsewhere, (See *Adeps* and *Olea*,) that all the fixed oils, whether liquid or concrete, consist of two proximate constituents, called *stearin* and *elain;* the former being solid, the latter a thin oil. When these are separately saponified, the stearin is found to be converted principally into *stearic* and *margaric* acids, and the elain chiefly into *oleic* acid. Oily and fatty bodies, therefore, which are rich in stearin, such as tallow and olive oil, will form the hardest soda soap.

The officinal soaps, the names of which are placed at the head of this article, embrace three soluble varieties, namely, two soda soaps, made respectively with olive and animal oil; and one potassa soap, under the name of soft soap. The soap of ammonia, also a soluble soap, is described under another head. (See *Linimentum Ammoniæ.*)

Preparation. Olive oil soda soap is usually prepared as follows. Barilla is bruised, and mixed with about one-third of its weight of slaked lime, and a portion of cold water is added to the mixture. At the end of about twelve hours, the liquor is drawn off, and constitutes what is called the first lixivium Two other lixivia are then obtained, by separate portions of water, which serve to exhaust the alkali from the residuum, and constitute weaker solu tions than the first. The next step consists in boiling the alkaline solution with the oil, which is mixed with one-fifth of rapeseed oil, to prevent the resulting soap from crumbling when it is cut. The ebullition is performed in large iron boilers. The weakest lixivium is first put into the boiler, to which a little oil is added, and the mixture is boiled. The combination soon takes place, and portions of the weaker solutions and of the oil are successively added, until the latter is expended. The strong lixivium is now added in successive small portions, and by completing the saturation of the oil, forms perfect soap, which separates from the remaining liquor and floats on the surface. This liquor, though abundant, consists principally of certain salts, which render it no longer fit for saponification. The fire is now allowed to fall, and the liquor in question is drawn off by a pipe, so as to leave the soap nearly dry. Fresh portions of strong lixivium are now added, the fire is rekindled, and the addition of the alkaline solution is continued, until the operator is satisfied that the saturation is complete. The remaining liquor is again drawn off as at first, so as to allow the soap, which floats on the surface, to sink to the bottom of the boiler. The soap is now of a bluish-black colour, and contains about sixteen per cent. of water. The colour arises from a combination of oil with alumina and the hydrosulphate of iron, constituting a kind of alumino-ferruginous soap.

The soap, in the state above described, may be converted either into white soap, or marbled soap, at the pleasure of the operator. To convert it into the former, it is diluted by degrees with the weaker lixivia, and the mixture is subjected to a regulated heat, and allowed to remain at rest. The dark-coloured alumino-ferruginous soap gradually falls to the bottom, leaving the soda soap perfectly white. This is drained, and run into *frames*, where it cools and hardens, after which it is cut into cakes or bars. When the soap as first obtained is to be converted into marbled soap, it is thinned to a certain extent with the weak lixivia, and allowed to cool gradually. The colouring matter separates in veins, and while the soap is still traversed with these, it is run into the frames, allowed to harden, and cut into bars. To succeed in the process of *marbling*, the soap must have a medium consistency; for if too thin, the colouring matter would fall to the bottom, and if too thick, this matter would become uniformly diffused through the soap.

Soap of soda, made as above described with olive oil, is manufactured principally in France and Spain, where the olive abounds. It is this soap which is meant by the officinal names *Sapo* of the U.S. Pharmacopœia, and *Sapo Durus* of the British Colleges. The London College indicates that imported from Spain, as the officinal kind.

Common soap (Sapo Vulgaris, *U.S.*) is also a soda soap, but instead of olive, it contains animal oil. This soap corresponds with the white soap of northern European countries and the United States, and is formed usually from barilla and tallow. In Scotland, it is manufactured from kelp and tallow. It was introduced into the lists of the U.S. Pharmacopœia, as the only soap proper for making opodeldoc. (See *Linimentum Saponis Camphoratum.*) This soap is made by boiling the alkaline lixivia, obtained from the barilla or kelp and added in successive portions, with the melted tallow, until the saponification is complete; after which the soap is lifted out and put into the frames to consoldidate.

Soft soap (Sapo Mollis) is prepared on the same general principles as hard soap; potash being employed as the alkali, and a fatty matter, rich in elaïn, as the oil. The French soft soap is made with the seed oils, such as rape-seed, hemp-seed, &c.; the Scotch, with fish oil and tallow; and our own with refuse fat and grease. A ley of wood-ashes is the form of potash usually employed. In the fabrication of this soap there is this peculiarity, that the soap formed, continues, throughout the whole process, to be dissolved in the alkaline solution; whereas, on the contrary, in making a soda soap, it is necessary for the success of the process, that the soap should separate from this solution. On this view, soft soap is a soap of potassa completely dissolved in the solution of its alkali, which consequently is present in excess. Soft soap is sometimes made with a view to its conversion into soda or hard soap. This conversion is effected by the addition of common salt, which, by double decomposition, generates a soap of soda, and muriate of potassa in solution.

Besides the officinal soaps of the British and United States Pharmacopœias, the preparation of which is above described, there are many other varieties, more or less used for medicinal or economical purposes. The officinal soap of the French Codex, called *amygdaline soap of soda*, is formed from soda and fresh almond oil, and is directed to be kept for two months before being used. *Starkey's soap*, also officinal in the Codex, is prepared by uniting, by trituration, carbonate of potassa with oil of turpentine and Venice turpentine. *Eau de luce* (aqua luciæ) is a kind of liquid soap, formed by mixing together a tincture of oil of amber and balsam of Gilead, with water of ammonia. *Transparent soap* is prepared by saponifying kidney fat with soda free from foreign salts, drying the resulting soap, dissolving it in alcohol, filtering and evaporating the solution, and running it into moulds when sufficiently concentrated. This soap is yellow, or yellowish-brown, and preserves its transparency after desiccation. *Palm soap* is prepared from palm oil and soda. It has a yellowish colour, and an agreeable odour of violets derived from the oil. *Almond soap* is made by dissolving equal parts of soap of olive oil and tallow soap in almond milk, formed from bitter almonds and infusion of roses, to which a little hydrocyanic acid is sometimes added. *Soap balls* are prepared by dissolving soap in a small quantity of water, and then forming it into a mass of the proper consistence, by means of starch. *Common yellow soap*, used for domestic purposes, derives its peculiarities from an admixture of rosin and a little palm oil with the tallow employed; the oil being added to improve its colour.

All the varieties of soap, except a few of the fancy sort and the olive oil soaps, are manufactured in the United States. These latter, which are chiefly used for medicinal purposes, are imported in largest amount from France. The total importation of soap for 1832 amounted to nearly eight hundred thousand pounds. The domestic export for the same time reached to nearly six millions of pounds.

Properties. Soap, whatever may be its colour, has the same general properties. Its aspect and consistence are familiar to every one. Its smell is peculiar, and its taste slightly alkaline. It is somewhat heavier than water, and therefore sinks in that liquid. Exposed to heat it quickly fuses, swells up, and is decomposed. It dissolves in water, and more readily in hot than in cold; and acids added to the solution, combine with the alkali, and set free the oleaginous acids, which being diffused through the water, produce a milky appearance. Its decomposition is also determined by all metallic salts, which invariably give rise to insoluble soaps. Soap is soluble also in cold, and abundantly in boiling alcohol. When dissolved in this menstruum it constitutes the tincture of soap, which forms a very convenient test for discovering earthy salts in mineral waters. Its use as a detergent depends upon its power of rendering grease and other soiling substances soluble in water, and, therefore, susceptible of being removed by washing.

Olive oil soda soap is also a hard soap, and is presented under two principal varieties, white and marbled. Good *white soap* has a slight yellowish tinge. In thin slices it is translucent, and to the touch it is neither greasy nor slippery. It ought not to grow moist, but, on the contrary, become dry by exposure to the air; without, however, being covered with any saline efflorescence. This variety of soap contains about forty-five per cent. of water. *Marbled soap* is harder and more constant in its proportions than white soap. It contains but thirty per cent. of water; and it is out of the power of the manufacturer to increase this quantity; whereas in making white soap, the operator may augment the proportion of this liquid to an almost indefinite extent, the soap being whiter in proportion as the quantity of water is greater. Marbled soap is, therefore, more economical than white soap for all the purposes to which it is applicable. That variety of marbled soap, called *Castile* in the shops, has its blue and red veins produced, the former by the addition of sulphate of iron to a part of the alkaline ley, after the soap is fully boiled; the latter by stirring in red oxide of iron, when the soap is nearly completed. (*Thomson, Lond. Dispensatory.*)

Animal oil soda soap, the *Sapo Vulgaris* of the United States Parmacopœia, is a hard soap, of a white colour, inclining to yellow. It possesses the same general properties as the olive oil soda soap.

Soft soap, as made in this country, is in the form of a semi-fluid slippery mass, capable of being poured from one vessel to another, and of a dirty yellow colour. This soap always contains an excess of alkali, which causes it to act more powerfully as a detergent than hard soap. That which is made in France has a greenish colour and the consistence of soft ointment, and is made from potassa, and hemp-seed oil. Sometimes it is manufactured from the dregs of olive oil.

Adulterations. When soap is made to unite with an excess of water, it becomes unnaturally white. Sometimes pulverized lime, gypsum, or pipe-clay, is incorporated with it, with fraudulent intentions. An excess of water may be known by the rapid loss of weight which the soap suffers in a dry air; and the latter substances are detected by acting on the soap with alcohol, which leave them undissolved.

Incompatibles. Soap is decomposed by all the acids, earths, and earthy and metallic salts. The acids combine with the alkali, and set free the oil; the earths unite with the oily matter, and separate the alkali; while the salts mentioned give rise, by double decomposition, to an insoluble soap of their base, and a saline combination between their acid and the alkali of the soap. All hard waters, in consequence of their containing lime, decompose and curdle soap.

Composition. As has been already explained, soap consists of certain oleaginous acids,resulting from the saponification of fats and oils, united with an alkali. Several of them have been analyzed by able chemists, and present considerable variation in their composition. According to Braconnot, Marseilles soap, which is an olive oil white soap, consists of soda 10.24, oleic acid 59.20, stearic acid 9.20, and water 21.36=100; and according to Thenard, marbled soap is composed of soda 6, fatty acids 64, water 30=100. The proportion of water is particularly variable; ranging, in different specimens, from twenty-one to forty-five per cent.

Medical Properties. Soap possesses the properties of a laxative and antacid. It is seldom given alone, but frequently in combination with rhubarb, the astringency of which it has a tendency to correct. Thus combined, it is frequently administered in dyspepsia, attended with constipation and torpor of the hepatic system. As it is readily decomposed by the weakest acids, which combine with the alkali, it has proved useful in acidity of the stomach, and has been recommended as a remedy in the uric acid diathesis; but it possesses no power to dissolve calculi, as was once supposed. Externally, soap is a stimulating discutient, and as such has been used, by frictions, in sprains and bruises. Dr. A. T. Thomson has seen much benefit derived from rubbing the tumid bellies of children in mesenteric fever, morning and evening, with a strong lather of soap. In pharmacy, soap is frequently employed for the purpose of giving proper consistency to pills; but care must be taken not to associate it with a substance which may be decomposed by it. It is also an ingredient in some liniments and plasters. In toxicology it is used as a counterpoison for the mineral acids, and should be always resorted to in poisoning by these agents without a moment's delay, and its use continued, until magnesia, the more appropriate antidote, can be obtained. The mode of administration, in these cases, is to give a teacupful of a solution of soap, made by dissolving it in four times its weight of water, every three or four minutes, until the patient has taken as much as he can swallow. The dose of soap is from three grains to half a drachm, given in the form of pill.

SARSAPARILLA. *U.S.*

Sarsaparilla.

"Smilax sarsaparilla, et aliæ. Radix. *The root.*" *U.S.*

Off. Syn. SARSAPARILLÆ RADIX. Smilax Sarsaparilla. Radix. *Lond.;* SMILACIS SARSAPARILLÆ RADIX. *Ed.;* SARSAPARILLA. SMILAX SARSAPARILLA. Radix. *Dub.*

Salsepareille, *Fr.;* Sarsaparille, *Germ.;* Salsapariglia, *Ital.;* Zarzaparrilla, *Span.*

Smilax. *Sex. Syst.* Diœcia Hexandria.—*Nat. Ord.* Asparagi, *Juss.;* Smilaceæ, *R. Brown, Lindley.*

Gen.Ch. Male. *Calyx* six-leaved. *Corolla* none. Female. *Calyx* six-leaved. *Corolla* none. *Styles* three. *Berry* three-celled. *Seeds* two. *Willd.*

Although the British and American Pharmacopœias, as well as most of those on the continent of Europe, recognise the root of the *Smilax Sarsaparilla* as officinal, it is very doubtful whether any of the drug as found in the shops is obtained from this species. The *S. Sarsaparilla* is a native of the United States, and its root would certainly be dug up and brought into the market, had it been found to possess the same properties with the imported medicine. It is not among the eleven species of *Smilax* described by Humboldt, Bonpland, and Kunth, who indicate the *S. officinalis, S. syphilitica,* and *S. Cumanensis,* especially the first, as the probable sources of the sarsaparilla exported from Mexico and the Spanish Main. In the present state of our knowledge on the subject, it is impossible to decide with certainty from what species the several commercial varieties of the drug are respectively derived. This much is highly probable, that they do not proceed from the same plant. Of the great number of species belonging to this genus, very few possess any useful medicinal power; and Hancock states that of the six or eight which he found growing in the woods of Guiana, only one presented in any degree the sensible properties of the genuine sarsaparilla, the rest being insipid and inert. The root of the *Smilax China*, a native of China and Japan, has been employed under the name of *China root* for similar purposes with the officinal sarsaparilla. As it occurs in commerce, it is in pieces from three to eight inches long and an inch or two thick, usually somewhat flattened, more or less knotty, often branched, of a brownish or grayish-brown colour externally, whitish or of a light flesh-colour internally, without odour, and of a taste flat at first, but afterwards very slightly bitterish and somewhat acrid like that of sarsaparilla. It is feeble as a medicine, and at present very little used. A root supposed to be that of the *Smilax aspera*, has been employed in India as a substitute for sarsaparilla. Parcels of it, imported into London, are described as consisting of long, tortuous, cylindrical, rugose roots, with the cortical portion resembling cork, and divided by furrows into moniliform rings. It has an aromatic odour and a bitter taste. (*Journ. of the Phil. Col. of Pharm.* vi. 202.)

Smilax Sarsaparilla. Willd. *Sp. Plant.* iv. 776; Woodv. *Med. Bot.* p. 161. t. 62. This plant is perennial, and like all of the same genus has a climbing or trailing stem, which in the present instance is long, slender, shrubby, angular, and beset with spines. The leaves are unarmed, ovate lanceolate, with about five nerves, somewhat glaucous beneath, and supported alternately upon footstalks, at the bases of which are long tendrils. The flowers usually stand three or four together upon a common peduncle, which is longer than the leafstalk. The name *sarsaparilla* is expressive of the character of the plant, being derived from two Spanish words which signify a small thorny vine.

S. officinalis. Humb. and Bonpl. *Plant. Æquinoct.* i. 271. In this species the stem is angular and prickly, and the leaves oblong oval, acuminate, cordiform, coriaceous, smooth, and furnished with five or seven nerves. According to Humboldt, it abounds on the river Magdalena, and is the *zarzaparilla* of the natives.

S. syphilitica. Humb. *Plant. Æquinoct.* This species has a round prickly stem, with scattered prickles, and very firm, oblong lanceolate, mucronate, three-nerved, coriaceous leaves. It grows in Venezuela and perhaps other parts of South America.

The medicinal species of Smilax grow in Mexico, Guatemala, and the warm latitudes of South America. The roots are very long and slender, and originate in a common head from which the stems of the plant rise. They are brought into the market from various sources, and are divided into several commercial varieties according to their place of collection or shipment.

The sarsaparilla most commonly used in this country is brought from the bay of *Honduras*, by which name it is known in commerce. It comes in bundles two or three feet long, composed of the roots folded lengthwise, and secured in a compact form by a few circular turns. These are packed in bales imperfectly covered with skins, each bale containing about one hundred pounds. The roots are usually connected at one extremity in large numbers in a common head, to which portions of the stems are also attached.

In some bundles are many small fibres either lying loose or still adhering to the roots.

The *Jamaica* or *red sarsaparilla* of foreign writers is not known by that name in the United States. As the island of Jamaica is said to be merely its channel of exportation to Europe, and as it is supposed to be originally from Honduras, it is probably confounded by our druggists with the Honduras sarsaparilla, from which it does not materially differ in properties. The reddish colour of its epidermis is its chief peculiarity.

Considerable quantities of the drug are imported from the Mexican ports of *Vera Cruz* and *Tampico*. It comes either in packages, like the Honduras, or in large, rather loose bundles, bound with cords or leather thongs, and usually containing the roots separately packed. These, as in the Honduras sarsaparilla, consist of a head or caudex with numerous long radicles, which, however, are somewhat smaller than in that variety, and have a thinner bark. They are often also much soiled with earth. The *Vera Cruz sarsaparilla* is not highly esteemed; but from the acrid taste which it possesses, it is probably not inferior in real virtues to the other kinds.

Another variety is the *Caracas sarsaparilla*, brought in large quantities from La Guayra. It is in oblong packages, of about one hundred pounds, surrounded with broad strips of hide, which are connected laterally with thongs of the same material, and leave much of the root exposed. The roots, as in the last variety, are separately packed, but more closely and with greater care. The radicles are often very amylaceous internally, in this respect resembling the following.

The *Brazilian*, or, as it is sometimes called in Europe, the *Lisbon sarsaparilla*, scarcely reaches the United States. Commanding a higher price in the European markets than in ours, it takes the former course. It grows in the country between the sources of the Orinoco, and the Rio Negro, a northern tributary of the Amazon, through which latter river it is conveyed to the Port of Para. It is celebrated throughout South America by the name of *sarsa of the Rio Negro*, and is considered as the most valuable variety of the drug. It is distinguished by the amylaceous character of its interior structure. Hence has probably arisen the value attached in Europe to sarsaparilla, from whatever source derived, which when broken exhibits a starch-like aspect. We are informed that our druggists find it profitable to export parcels of this character when they happen to reach our market. But the Brazilian drug, if really more efficient, must owe its superiority to some other cause than the abundance of starch which it contains.

Properties. The dried sarsaparilla roots are several feet in length, abou the thickness of a goose-quill, cylindrical, more or less wrinkled longitudinally, flexible, and composed of a thick exterior cortical portion coverec with a thin easily separable epidermis, of an inner layer of ligneous fibre and of a central pith. The epidermis is of various colours, generally, in th *Honduras* variety, of a dirty ash-colour, sometimes very dark, and ofte more or less deeply tinged with red. The cortical portion is in some specimens whitish, in others brown, and not unfrequently of a pink or rosy hue It is occasionally white, brittle, and almost powdery like starch. The wood part is usually very thin, and composed of longitudinal fibres, which allov the root to be split with facility through its whole length.

Sarsaparilla is in its ordinary state nearly or quite inodorous, but in decoction acquires a decided and peculiar smell. To the taste it is mucilag nous and very slightly bitter, and, when chewed for some time, produces disagreeable acrid impression which remains long in the mouth and fauces

The root is efficient in proportion as it possesses this acrimony, which is said by some authors to be confined to the cortical portion, while the ligneous fibre and medullary matter are insipid and inert. Hancock avers that all parts are equally acrid and efficacious. The truth is probably between the two extremes; and, as in most medicinal roots, it must be admitted that the bark is more powerful than the interior portions, while these are not wholly inactive. The virtues of the root are communicated to water cold or hot, but are impaired by long boiling. (See *Decoctum Sarsaparillæ.*) They are extracted also by diluted alcohol. It appears from the experiments of Hancock that the whole of the active principle is not extracted by water. He observes in his paper upon sarsaparilla published in the London Medico-Botanical Transactions, when speaking of the sarsaparilla from Para and the Rio Negro, "after exhausting half a pound of this sort by two digestions, boiling and pressure, I added to the dregs half a pint of proof spirit, and digested this with a gentle heat for a few hours in a close vessel, then affusing hot water to the amount of that taken off from the first boiling, and pressing again, I procured by the last operation about four pints of an infusion which possessed the acrid properties of the sarsa in a much higher degree even than that obtained by the first decoction with simple water." It appears that in South America it is the custom to prepare sarsaparilla by digestion in wine or spirit, or by infusion in water with additions which may produce the vinous fermentation, and thus add alcohol to the menstruum. The same result, as to the superior efficacy of alcohol as a solvent of the acrid principle of sarsaparilla, has been obtained by the French experimentalists.*

According to M. Thubeuf, sarsaparilla contains, 1. a peculiar crystalline substance, which is probably the active principle of the root, 2. a colouring substance, 3. resin, 4. starch, 5. lignin, 6. a thick, aromatic fixed oil, 7. a waxy substance, and 8. muriate and nitrate of potassa. The proportion of starch is large. The crystalline principle in which the virtues of sarsaparilla probably reside should be called *sarsaparillin.* It was first discovered by Dr. Palotta, who described it in 1824, under the name of *pariglin.* Subsequently, M. Folchi supposed that he had found another principle which he called *smilacin.* In 1831, M. Thubeuf announced the discovery of a new substance in sarsaparilla, which he named *salseparine*, from the French name of the root. Finally, Batka, a German chemist, towards the end of 1833, published an account of a principle which he had discovered in the root, and which, under the impression that it possessed acid properties, he called *parillinic acid.* M. Poggiale, however, has recently shown that these substances are identical, and differ only in the processes by which they were procured. The process of M. Thubeuf, which is decidedly preferable to he others, is the following. The root is treated with hot alcohol till deprived of taste. The tincture thus obtained is submitted to distillation and even-eighths of the alcohol drawn off. The remainder is treated with nimal charcoal, and filtered at the end of twenty-four or forty-eight hours. The sarsaparillin is deposited in the form of a granular powder. This s dissolved in a fresh portion of alcohol and crystallized. The alcoholic nother liquors may be deprived of that portion of the principle which they etain by evaporating to dryness, dissolving the product in water, filtering, gain evaporating to dryness, redissolving in alcohol, and crystallizing. *Sarsaparillin* is white, inodorous, almost tasteless in the solid state, but of bitter, acrid, nauseous taste when dissolved in alcohol or water. It is very slightly soluble in cold water, but is more readily dissolved by boiling water which deposites it on cooling. It is very soluble in alcohol, especially at a boiling temperature. Ether and the volatile oils also dissolve it. Water which holds it in solution has the property of frothing very much by agitation. The solutions of sarsaparillin, are without either acid or alkaline reaction. Batka erred in considering it an acid. M. Poggiale found it both in the cortical and medullary part of the root, but most largely in the former. Palotta gave it internally in doses varying from two to thirteen grains, and found it to produce nausea and to diminish the force of the circulation. It is probably the principle upon which sarsaparilla depends chiefly, if not exclusively, for its remedial powers; but this opinion needs the support of further observation before it can be admitted as an established fact. (*Journ. de Pharm.* xx. 553 and 679.)

---

* See a paper by M. Soubeiran, Journ. de Pharm. tom. xvi. p. 38. an. 1830.

The sarsaparilla of the shops is very apt to be nearly if not quite inert, either from age, or from having been obtained from an inferior species of Smilax. This inequality of the medicine, together with the improper modes of preparing it which have been long in vogue, have probably contributed to its variable reputation. The only criterion of good sarsaparilla which can be relied on is the taste. If it leave a decidedly acrid impression in the mouth after having been chewed for a short time, it may be considered efficient; if otherwise, it is probably inert.

Medical Properties and Uses. Few medicines have undergone greater changes of reputation. About the middle of the sixteenth century it was introduced into Europe as a remedy for the venereal complaint, in the treatment of which it had been found very useful in the recent Spanish settlements in the West Indies. After a time it fell into disrepute, and was little employed till nearly a century ago, when it was again brought into notice by Sir William Fordyce and others, as a useful adjuvant and corrigent of mercury in lues venerea. Since that period very different opinions have been entertained of its efficacy. Some, among whom was Dr. Cullen, considered it wholly inert; others, on the contrary, have had the most unbounded confidence in its powers. The probable cause of much of this discrepancy has been already mentioned. Experience, both among regular practitioners and empyrics, would seem to have placed its efficiency beyond reasonable doubt; and at this moment its reputation is probably as high as at any former period. Its most extensive and useful application is to the treatment of secondary syphilis and syphiloid diseases, and that shattered state of the system which sometimes follows the imprudent use of mercury in these affections. It is also employed, though with less obvious benefit, in chronic rheumatism, scrofulous affections, certain cutaneous diseases, and other depraved conditions of the general health to which the physician may find it difficult to apply a name. Its mode of action is less evident than its ultimate effects. It is said to increase the secretion of perspiration and urine; but allowing it to possess this power, the amount of effect is too trifling to explain its influence over disease; and the diaphoretic and diuretic action which it appears to evince, may perhaps be as justly ascribed to the medicines with which it is generally associated, or the liquid in which it is exhibited. In this ignorance of its precise *modus operandi* we may call it an alterative, as we call all those medicines which change existing morbid actions, without an obvious influence over any of the functions.

Sarsaparilla may be given in powder in the dose of half a drachm or a drachm three or four times a day; but it is more conveniently administered in the form of infusion, decoction, syrup, or extract. (*See the several offi-*

cinal preparations in Part II.) A beer made by fermenting an infusion of the drug with molasses, is said to be a popular remedy in South America.*

Laurus Sassafras. Willd. *Sp. Plant.* ii. 485; Bigelow, *Am. Med. Bot.* ii. 142; Michaux, *N. Am. Sylv.* ii. 144. This is an indigenous tree of middling size; rising in favourable situations from thirty to fifty feet in height, with a trunk about a foot in diameter. In the Southern States it is sometimes larger, and in the northern parts of New England is little more than a shrub. The bark which covers the stem and large branches is rough, deeply furrowed, and grayish; that of the extreme branches or twigs is smooth and beautifully green. The leaves, which are alternate, petiolate, and downy when young, vary much in their form and size even upon the same tree. Some are oval and entire, others have a lobe on one side; but the greater umber are three-lobed. Their mean length is four or five inches. The lowers, which are frequently diœcious, are small, of a pale yellowish-green olour, and disposed in racemes which spring from the branches below the eaves, and have linear bractes at their base. The corolla is divided into six blong segments. The male flowers have nine stamens; the hermaphrodite, vhich are on a different plant, have only six, with a simple style. The fruit s an oval drupe, about as large as a pea, of a deep blue colour when ripe, and upported on a red pedicel, which enlarges at the extremity into a cup for its eception.

---

* The following is a formula recommended by Hancock. "Take of Rio Negro sarsa, ruised, 2℔; bark of guaiac, powdered. 8 oz.; raspings of guaiac wood, anise seeds, nd liquorice root, each 4 oz.; mezereon, *bark of the root*, 2 oz.; treacle [molasses] 2℔; nd a dozen bruised cloves; pour upon these ingredients about four gallons of boiling waer, and shake the vessel thrice a day. When a fermentation has well begun, it is fit for se, and may be taken in the dose of a small tumblerful twice or thrice a day." This ormula is worthy of attention; but the bark of guaiacum, which is not kept in the shops, ight be omitted without materially affecting the virtues of the preparation.

The sassafras is common throughout the United States, and extends into Mexico. It is said also to grow in Brazil and Cochin-china. In this country it is found both in woods and open places, and is apt to spring up in the neighbourhood of cultivation, and in neglected or abandoned fields. In Pennsylvania and New York it blooms in the beginning of May; but much earlier at the South. The fresh flowers have a slightly fragrant odour, and almost all parts of the plant are more or less aromatic. The wood and root are directed by the British Pharmacopœias, the bark of the root, and the pith of the twigs or extreme branches, by that of the United States. The wood is porous, light, fragile, whitish in the young tree, reddish in the old, and but feebly endowed with aromatic properties. It is sent to Europe in billets invested with the bark; but is not employed in this country. The root is more commonly exported, and is the part chiefly used in British pharmacy. It consists of a brownish-white wood, covered with a spongy bark divisible into layers. The latter portion is by far the most active, and is usually kept in our shops in a separate state.

1. *Sassafras Pith.* This is in slender cylindrical pieces, very light and spongy, with a mucilaginous taste, having in a slight degree the characteristic flavour of the sassafras. It abounds in a gummy matter which it readily imparts to water, forming a limpid mucilage, which, though ropy and viscid, has much less tenacity than that of gum Arabic, and will not answer as a substitute in the suspension of insoluble substances. It differs also from solutions of ordinary gum, in remaining perfectly limpid when added to alcohol. This mucilage is much employed as a mild and soothing application in inflammation of the eyes; and forms a pleasant and useful drink in dysenteric, catarrhal, and nephritic diseases. It may be prepared by adding a drachm of the pith to a pint of boiling water.

2. *Bark of Sassafras Root.* As found in the shops, this is usually in small irregular fragments, sometimes invested with a brownish epidermis, sometimes partially or wholly freed from it, of a reddish or rusty cinnamon hue, very brittle, and presenting when freshly broken a lighter colour than that of the exposed surfaces. Its odour is highly fragrant, its taste sweetish, and gratefully aromatic. These properties are extracted by water and alcohol. They reside in a volatile oil which may be obtained separate by distillation with water. (See *Oleum Sassafras.*)

Medical Properties and Uses. The bark of sassafras root is stimulant, and perhaps diaphoretic, though its possession of any peculiar tendency to the skin, independently of its mere excitant property, is quite doubtful. It is used almost exclusively as an adjuvant to other more efficient medicines, the flavour of which it improves, while it renders them more cordial to the stomach. The complaints for which it has been particularly recommended, are chronic rheumatism, cutaneous eruptions, and scorbutic and syphiloid affections. As a remedy in lues venerea, in which it formerly had a high reputation, it is now universally considered as in itself wholly inefficient. It is most conveniently administered in the form of infusion. The oil may also be given. As the active principle is volatile, the decoction and extract are useless preparations.

Convolvulus Scammonia. Willd. *Sp. Plant.* i. 845; Woodv. *Med. Bot.* p. 243. t. 86. This species of Convolvulus has a perennial, tapering root, from three to four feet long, from nine to twelve inches in circumference, branching towards its lower extremity, covered with a light gray bark, and containing a milky juice. The stems are numerous, slender, and twining, extending sometimes to the distance of fifteen or twenty feet upon the ground or on neighbouring plants, aud furnished with smooth, bright green, arrow-shaped leaves, which stand alternately upon long footstalks. The flowers are placed in pairs, or three together upon the pedicels, which are round, axillary, solitary, and of nearly twice the length of the leaf.

The plant is a native of Syria, and the neighbouring countries. No part is medicinal except the root, which when dried, was found by Dr. Russel to be a mild cathartic. Scammony is the concrete juice of the fresh root, and is collected, according to Russel, in the following manner. In the month of June, the earth is cleared away from about the root, the top of which is cut off obliquely about two inches from the origin of the stems. The milky juice which exudes is collected in shells or other convenient receptacle, placed at the most depending part of the cut surface. A few drachms only are collected from each root. The juice from several plants is put into any convenient vessel, and concretes by time. In this state it constitutes genuine scammony, but is very seldom exported. It is generally prepared for the market by admixture, while it is yet soft, with the expressed juice of the stalks and leaves, with wheat flour, ashes, fine sand, &c.; and there is reason to believe that scammony sometimes consists wholly or in great part of the expressed juice of the root evaporated to dryness by exposure to the sun, or by artificial heat. The drug produced in Syria is called *Aleppo scammony*, from the place whence it is sent out of the country. There is another variety called *Smyrna scammony*, which is of uncertain origin, but supposed by some to be derived from the *Periploca Scammone*, and named from its place of export. In the South of France, a substance prepared from the expressed juice of the *Cynanchum Monspeliacum*, is sold by the name of *Montpellier scammony*, and is said to be brought into this country from Marseilles. Each of these varieties deserves a separate notice.

1. *Aleppo scammony.* This seldom or never reaches us in its purest state. It is described as in small masses, often porous, sometimes uniform, of a reddish or whitish-gray colour, breaking with a dull waxy fracture, forming when rubbed with the saliva a greenish-yellow emulsion, and pos-

sessing a strong disagreeable odour. The *Aleppo Scammony* brought to our market is contained in drums, in large irregular rather heavy masses, breaking with a faintly shining fracture, and exhibiting when broken a structure generally somewhat porous, sometimes cavernous, occasionally almost compact. The colour externally is usually a dark ash or olive; internally it is lighter and sometimes slightly tinged with yellow, but speedily deepens on exposure. The small fragments are somewhat translucent at the edges. The mass is easily pulverized, and yields a light gray powder. It imparts to water with which it is triturated a greenish milky appearance. The smell is rather disagreeable, but said to resemble that of old cheese made from ewe's milk. The taste is bitterish and slightly acrid.

2. *Smyrna scammony.* This is in flat cakes, darker, more compact, heavier, and harder than the preceding variety, less easily pulverized, of a dull and earthy fracture, a bitter acrid taste, and an odour which though disagreeable is different from that of genuine scammony. Its watery solution is opaque and of a dirty white colour. It is much inferior to Aleppo scammony; but is scarcely known as a distinct variety in our market. Under the name, however, of *Smyrna scammony*, a substance is found in some of our drug stores, said to be imported from Marseilles, which is evidently factitious, and may be considered as nearly or altogether worthless. It is in circular cakes or fragments of such cakes, rather more than half an inch thick, very light, almost black externally, penetrated with small holes as if worm eaten, and when broken exhibiting an irregular cellular, spongy texture.

3. The *Montpellier scammony* is black, hard, compact, and when rubbed with the moistened finger, becomes dark gray, unctuous, and tenacious. Its smell is weak and disagreeable, and its taste nauseous. We are not aware that it is imported; but as scammony is sometimes brought from the South of France, our druggists should be on their guard against it. It is said to be more irritating and less purgative than the Aleppo scammony, which it is sometimes employed to adulterate.

Scammony is ranked among the gum-resins. It is partially dissolved by water, more largely by alcohol, and entirely, with the exception of impurities, by diluted alcohol. Its chief constituent is resin, which constitutes more than two-thirds of the weight of Aleppo scammony. Bouillon-Lagrange and Vogel obtained from 100 parts of *Aleppo scammony* 60 of resin, 3 of gum, 2 of extractive, and 35 of insoluble matter; from the same quantity of *Smyrna scammony* 29 parts of resin, 8 of gum, 5 of extractive, and 58 of vegetable remains and earthy substances.

Medical Properties and Uses. Scammony is an energetic cathartic, apt to occasion griping, and sometimes operating with harshness. It was known to the ancient Greek physicians, and was much employed by the Arabians, who not only gave it as a purgative, but also applied it externally for the cure of various cutaneous diseases. It may be used in all cases of torpid bowels, when a powerful impression is desired; but on account of its occasional violence is seldom administered, except in combination with other cathartics, the action of which it promotes, while its own harshness is mitigated. It should be given in emulsion with mucilage, sugar, almonds, liquorice or other demulcent; and its disposition to gripe may be counteracted by the addition of an aromatic. The dose is from five to ten grains.

Scilla. *Sex. Syst.* Hexandria Monogynia.—*Nat. Ord.* Asphodeleæ.

Gen. Ch. *Corolla* six-petaled, spreading, deciduous. *Filaments* thread-like. *Willd.*

Scilla maritima. Willd. *Sp. Plant.* ii. 125; Woodv. *Med. Bot.* p. 745. t. 255. This is a perennial plant, with fibrous roots proceeding from the bottom of a large bulb, which sends forth several long, lanceolate, pointed, somewhat undulated, shining, deep-green leaves. From the midst of the leaves a round, smooth, succulent flower-stem rises, from one to three feet high, terminating in a long, close spike of whitish flowers. These are destitute of calyx, and stand on purplish peduncles, at the base of each of which is a linear, twisted, deciduous floral leaf.

The squill grows on the seacoast of Spain, France, Italy, Greece, and the other countries bordering on the Mediterranean. The bulb is the officinal portion. It is generally dried for use; but it is sometimes imported into this country in the recent state, packed in sand.

Properties. The fresh bulb is pear-shaped, usually larger than a man's fist, sometimes as large as the head of a child, and consisting of fleshy scales, attenuated at their edges, closely applied over each other, and invested by exterior scales so thin and dry as to appear to constitute a membranous coat. In the variety generally employed, this exterior coating is of a deep reddish-brown colour, and the inner scales have a whitish rosy or very light pink epidermis, with a yellowish-white parenchyma. In another variety the whole bulb is white. They do not differ in their medicinal virtues. The bulb abounds in a viscid, very acrid juice, which causes it to inflame and even excoriate the skin when much handled. By drying, this acrimony is very much diminished, with little loss of medicinal power. The bulb loses about four-fifths of its weight in the process. Vogel found 100 parts of fresh squill to be reduced to 18 by desiccation. The process is somewhat difficult, in consequence of the abundance and viscid character of the juice. The bulb is cut into thin transverse slices, and the pieces dried separately by artificial or solar heat. The outer and central scales are rejected, the former being dry and destitute of the active principle, the latter too fleshy and mucilaginous. The British Colleges give directions in relation to the drying of squill; and the Dublin College orders it to be reduced to powder, and kept in phials with ground stoppers.

Dried squill, as found in our shops, is in irregular oblong pieces, often more or less contorted, of a dull yellowish-white colour with a reddish or rosy tint, sometimes entirely white, slightly diaphanous, brittle and pulverizable when perfectly dry, but generally flexible from the presence of moisture, for which they have a great affinity. Occasionally a parcel will be found consisting of vertical slices, some of which adhere together at their base. The odour is very feeble, the taste bitter, nauseous, and acrid.

The virtues of squill are extracted by water, alcohol, and vinegar. According to Vogel, it contains a peculiar very bitter principle named by him *scillitin*, gum, tannin, traces of citrate of lime and saccharine matter, lignin, and an acrid principle which he was unable to isolate. Water distilled from it had neither taste nor smell, and was drank by Vogel to the amount of six ounces without producing any effect. From the experiments of Duncan and Buchner it appears, that tannin, if it exists in squill, is in very small proportion. The *scillitin* of Vogel is soluble in water, alcohol, and vinegar; but it is considered by M. Tilloy of Dijon, whose analysis is more recent, as a compound of the proper active principle of squill with gum and uncrystallizable sugar. The *scillitin* obtained by the latter experimenter, was insoluble in water and in dilute acids, soluble in alcohol, exceedingly acrid and bitter to the taste, and very powerful in its influence on the animal system. A single grain produced the death of a strong dog. The following is the process of M. Tilloy. Dried squill is macerated in alcohol of 33° Baumé, the resulting tincture evaporated to the consistence of syrup, and the extract treated with alcohol of 35°. The alcoholic solution is evaporated, and the residue treated first with ether and subsequently with water. The aqueous solution, filtered and evaporated, yields a substance analogous to the scillitin of Vogel. To obtain the principle pure, the aqueous solution is treated with animal charcoal before evaporation. The matter obtained is dissolved in alcohol, ether is added to precipitate the sugar, and the active principle remains in the mixed liquor, from which it may be obtained by evaporation. According to M. Tilloy, this proceeding should be repeated several times. (*Dict. des Drogues.*) M. Chevallier thinks that the active principle of squill has not yet been entirely isolated.

When kept in a dry place, squill retains its virtues for a long time; but if exposed to moisture, it soon becomes mouldy.

Medical Properties and Uses. Squill is expectorant, diuretic, and in large doses emetic and purgative. In overdoses it has been known to occasion hypercatharsis, strangury, bloody urine, and fatal inflammation of the stomach and bowels. The Greek physicians employed it as a medicine; and it has retained to the present period a deserved popularity. As an expectorant, it is used both in cases of deficient and of superabundant secretion from the bronchial mucous membrane, in the former case usually combined with tartar emetic or ipecacuanha, in the latter frequently with the stimulant expectorants. In both instances, it operates by stimulating the vessels of the lungs; and where the inflammatory action in this organ is considerable, as in pneumonia and severe catarrh, the use of squill should be preceded by the lancet. In dropsical diseases it is very much employed, especially in connexion with calomel, which is supposed to excite the absorbents, while the squill increases the secretory action of the kidneys. In these complaints also it is thought to succeed best in the absence of general inflammatory excitement. On account of its great uncertainty and occasional harshness as an emetic, it is very seldom prescribed, except in infantile croup or catarrh, in which it is usually given in the form of syrup or oxymel. When given in substance, it is most conveniently administered in the form of pill. The dose, as a diuretic or expectorant, is one grain, repeated two or three times a day, and gradually increased till it produces slight nausea, or evinces its action upon the kidneys or lungs. From six to twelve grains will generally vomit.

SCROPHULARIA NODOSA. Folia. *Dub.*

Figwort Leaves.

Scrophulaire noueuse, *Fr.;* Braunwurzel, *Germ.;* Scrofolaria nodosa, *Ital.;* Escrofularia, *Span.*

Scrophularia. *Sex. Syst.* Didynamia Angiospermia.—*Nat. Ord.* Scrophularineæ.

Gen. Ch. *Calyx* five-cleft. *Corolla* subglobular, resupine. *Capsule* two-celled. *Willd.*

Scrophularia nodosa. Willd. *Sp. Plant.* iii. 270; Smith, *Flor. Brit.* 663. The root of the *knotty rooted figwort* is perennial, tuberous, and knotty; the stem is herbaceous, erect, quadrangular, smooth, branching, and from two to three feet high; the leaves are opposite, petiolate, ovate cordate, pointed, sharply toothed, veined, and of a deep-green colour; the flowers are small, dark purple, slightly drooping, and borne on branching peduncles in erect terminal bunches.

The plant is a native of Europe, where it grows in shady and moist places, and flowers in July.

The leaves, which are the part used, have when fresh a rank fetid odour, and a bitter somewhat acrid taste; but these properties are diminished by drying. Water extracts their virtues, forming a reddish infusion, which is blackened by the persulphate of iron.

Medical Properties and Uses. Figwort leaves are said to be anodyne and diuretic, and to have repellent properties when externally applied. They were formerly considered tonic, diaphoretic, discutient, anthelmintic, &c.; and were thought to be useful in scrofula. They are at present very little employed, and never in this country. In Europe they are sometimes applied in the form of ointment or fomentation to piles, painful tumours and ulcers, and cutaneous eruptions.

SECALE CORNUTUM. *U.S.*

Spurred Rye. Ergot.

"Secale cereale. Semen morbo affectum. *The diseased seed.* Vel, Scle-otium clavus. *De Candolle.*" *U.S.*

Seigle ergoté, *Fr.;* Mutterkorn, *Germ.*

In several of the grains, the place of the seed is occupied by a morbid ex-rescence, which, from its resemblance to the spur of a cock, has received he name of *ergot*, adopted from the French. This excrescence occurs ost frequently in the rye, *Secale cereale* of botanists, and having been und, as produced by this plant, to possess valuable medicinal properties, as been introduced into the Pharmacopœia of the United States, under the reviously recognised title of *Secale cornutum*, or *spurred rye.* In the last dition of the Pharmacopœia it was transferred to the primary from the condary list, in which it was first placed.

Considerable difference of opinion has prevailed in relation to the nature this singular substance. At one time it was thought to be merely the seed tered by disease; and the opinion was maintained, that the morbid action epended on the puncture of an insect and the deposition of its egg, which by irritating the neighbouring parts gave rise to this excrescence, as the gall is produced in the oak. De Candolle, however, considers it a parasitic plant, belonging to the natural family of the *Fungi*, and the genus *Sclerotium*, and denominates it *Sclerotium Clavus*. An intermediate opinion is advocated by M. Léveillé, who, after careful observation of the development of the ergot, published the result of his inquiries in the Annals of the Linn. Society of Paris for the year 1826. According to this author, a soft viscid tubercle may be seen at the earliest stage of the flower, surmounting the germ, the character of which it changes, without preventing its growth. The germ becomes of a dark colour, and increasing in size pushes the tubercle before it, which also expands, and exudes a viscid matter, which spreads over the germ, and drying upon its surface, gives it a thin yellowish coating. This tubercle M. Léveillé considers a parasitic fungus, for which he proposes the name *Sphacelia segetum;* and the ergot is thus composed of the diseased grain incorporated with a distinct and independent vegetable production. It is in the coating given by the latter to the enlarged seed that he supposes the virtues of the spurred rye to reside; and very dry or very wet seasons are equally unfavourable to the full development of the medicine, the former because the coating breaks into scales and falls off, the latter because it is washed away by the rain. These statements need confirmation before they can be implicitly received.

Rye is most subject to this disease in poor and wet soils, and in rainy seasons. Intense heat succeeding continued rains is said to favour its development. The ergot usually projects out of the glume or husk beyond the ordinary outline of the spike or ear. In some spikes the place of the seeds is wholly occupied by the ergot, in others only two or three spurs are observed. It is stated that this substance is much more energetic when collected before than after harvest.

Properties. Ergot is in solid, brittle yet somewhat flexible grains, from six lines to an inch and a half long, from half a line to two lines in thickness, usually curved like a spur, tapering from near the middle, obtuse at the extremities, marked with a deep longitudinal furrow on one or both sides, of a violet-brown colour externally, yellowish-white within, of an unpleasant smell when in mass resembling that of putrid fish, and of a taste which is at first scarcely perceptible, but ultimately disagreeable and slightly acrid. It imparts its virtues to water and to alcohol. Vauquelin obtained from it—1. a yellowish fawn-coloured matter soluble in alcohol, 2. a violet colouring matter insoluble in alcohol but soluble in water, 3. a sweetish oleaginous substance in great abundance, 4. a fixed acid, probably the phosphoric, 5. an azotized substance in large proportion which easily became putrid, and 6. free ammonia, which escaped at the temperature of boiling water. According to a recent analysis by a German chemist of the name of Wiggers, ergot contains 35.0 per cent. of a peculiar fixed oil; 1.04 of a peculiar, white, crystallizable, very soft fatty matter; 0.75 of cerin; 46.18 of a substance analogous to fungin or the fleshy substance of mushrooms; 1.24 of a reddish-brown substance of a peculiar nauseous odour, and a bitter slightly acrid taste, soluble in alcohol, but insoluble in water and ether, and called *ergotin* by the discoverer, under the impression that it might be the active principle of ergot; 7.76 of a substance resembling osmazome; 1.55 of a peculiar saccharine matter; 2.32 of gummy extractive combined with an azotized colouring principle; and 1.46 of albumen; besides saline and earthy matters in minute proportion. (*Journ. de Pharm.* xviii. 534.)

Medical Properties and Uses. Given in small doses, ergot produces, in the system of the male, no obvious effects; but in the female, exhibits a strong tendency to the uterus, upon the contractile property of which it operates with great energy. It is perhaps the only medicine which specifically promotes contraction in this organ. In the quantity of half a drachm or a drachm it often occasions nausea or vomiting, and in still larger doses excites headach and febrile symptoms, and sometimes operates unpleasantly upon the brain. Its long continued use is highly dangerous, even when no immediate effects are perceptible. Terrible and devastating epidemics in different parts of the continent of Europe, particularly in certain provinces of France, have long been ascribed to the use of bread made from rye contaminated with this degenerate grain. Dry gangrene, typhus fever, and disorder of the nervous system attended with convulsions, are the forms of disease which have been observed to follow the use of this unwholesome food. It is true that ergot has been denied to be the cause; but accurate investigations made by competent men upon the spot where the epidemics have prevailed, together with the result of experiments made upon inferior animals, leave no room for reasonable doubt upon the subject.

The most important remedial application of ergot is founded on its power of promoting the contraction of the uterus. On the continent of Europe, in various parts of Germany, France, and Italy, it has long been empyrically employed by midwives for this purpose; and its German name of *mutterkorn* implies a popular acquaintance with its peculiar powers. But the attention of the medical profession was first called to it by a letter from Dr. Stearns of Saratoga county, in the state of New York, addressed to Dr. Ackerly, A.D. 1807, and published in the eleventh volume of the New York Medical Repository. Since that period the journals have teemed with communications attesting its efficacy in facilitating parturition; and though it has failed in the hands of some physicians, the general opinion of the profession is so decidedly in its favour, that it may now be considered among the established articles of the materia medica. When it has proved wholly inefficient, the result is probably ascribable to the inferior character of the particular parcel employed. In its operation upon the pregnant uterus it produces a constant unremitting contraction and rigidity, rather than that alternation of spasmodic effort and relaxation which is observable in the natural process of labour. Hence, unless the os uteri and external parts are sufficiently relaxed, the medicine would be likely to produce injury to the child by the incessant pressure which it maintains. Such in fact has been the observation of numerous practitioners, and the death of the infant is thought not unfrequently to result from the injudicious employment of the medicine. The cases to which it is thought to be especially adapted are those of lingering labour, when the os uteri is sufficiently dilated, and the external passages sufficiently relaxed, when no mechanical impediment is offered to the passage of the child, and the delay is ascribable solely to want of energy in the uterus. Other cases are those in which the death of the fœtus has been ascertained, and when great exhaustion or dangerous constitutional irritation imperiously calls for speedy delivery. The remedy may also be given to promote the expulsion of the placenta, to restrain inordinate hemorrhage after delivery, and to hasten the discharge of the fœtus in protracted cases of abortion. In women subject to dangerous flooding, a dose of ergot given immediately before delivery is said to have the happiest effects. In menorrhagia and uterine hemorrhage, unconnected with pregnancy, the medicine has long been empyrically employed; and is now found highly useful in the hands of regular practitioners. Its use has even been extended to hemorrhages from other organs, and with reputed good effect. Cases of hemorrhage from the lungs are recorded in which ergot has proved highly beneficial. It has also been employed in amenorrhœa, but not with encouraging success. Gonorrhœa, gleet, and leucorrhœa are among the complaints in which it has been recommended.

Ergot is given in substance, infusion, or decoction. The dose of the powder to a woman in labour is fifteen or twenty grains, to be repeated every twenty minutes, till its peculiar effects are experienced, or till the amount of a drachm has been taken. Of an infusion made in the proportion of one drachm of the ergot to four fluidounces of water, one-third may be given for a dose, and repeated with the same interval. For other purposes the dose of the medicine is ten or fifteen grains, repeated three times a day, and gradually increased, but not continued for a great length of time.

Ergot should be powdered only when wanted for use. W.

SENEGA.

Seneka.

"Polygala senega. Radix. *The Root.*" *U.S.*

Off. Syn. SENEGÆ RADIX. Polygala Senega. Radix. *Lond.;* POLYGALÆ SENEGÆ RADIX. *Ed.;* POLYGALA SENEGA. Radix. *Dub.*

Polygale de Virginie, *Fr.;* Klapperschlangenwurzel, *Germ.;* Poligala Virginiana, *Ital.*

POLYGALA. *Sex. Syst.* Diadelphia Octandria.—*Nat. Ord.* Polygaleæ.

Gen. Ch. Calyx five-leaved, with two leaflets wing-shaped, and coloured. *Legume* obcordate, two celled. *Willd.*

Besides the *P. Senega*, two other species have attracted some attention in Europe—the *P. amara* and *P. vulgaris*—as remedies in chronic pectoral affections; but as they are not natives of this country, and are never used by practitioners here, they do not merit particular notice.

Polygala Senega. Willd. *Sp. Plant.* iii. 894; Bigelow, *Am. Med. Bot.* ii. 97; Barton, *Med. Bot.* ii. 111. This unostentatious plant has a perennial branching root, from which several erect, simple, smooth, round, leafy stems annually rise, from nine inches to a foot in height. The stems are occasionally tinged with red or purple in their lower portion, but are green near the top. The leaves are alternate or scattered, lanceolate, pointed, smooth, bright green on the upper surface, paler beneath, and sessile or supported on very short footstalks. The flowers are small, white, and arrange in a close spike at the summit of the stem. The calyx is the most conspicuous part of the flower. It consists of five leaflets, two of which are wingshaped, white, and larger than the others. The corolla is small and closed The capsules are small, much compressed, obcordate, two-valved, two-celled and contain two oblong ovate, blackish seeds, pointed at one extremity.

This species of Polygala, commonly called *Seneka snakeroot*, grows wil in all parts of the United States, but most abundantly in the southern an western sections, where the root is collected in great quantities for sale. I is brought into market in bales weighing from fifty to four hundred pounds.

Properties. As the root occurs in commerce, it is of various sizes, fro that of a small quill to that of the little finger, presenting a thick knotty hea which exhibits traces of the numerous stems. It is tapering, branched, variously twisted, often marked with crowded annular protuberances, and wit a projecting keel-like line, extending along its whole length. The epiderm is corrugated, transversely cracked, of a yellowish-brown colour in the youn roots, and brownish-gray in the old. In the smaller branches the colour is a lighter yellow. The bark is hard and resinous, and contains the active principles of the root. The central portion is ligneous, white, and quite inert, and should be rejected in the preparation of the powder. The colour of this is gray. The odour of seneka is peculiar, strong in the fresh root, but faint in the dried. The taste is at first sweetish and mucilaginous, but after chewing becomes somewhat pungent and acrid, leaving a peculiar irritating sensation in the fauces. These properties, as well as the medical virtues of the root, are extracted by boiling water, and by alcohol; but the alcoholic solution is said to be less acrid than the decoction. Diluted alcohol is an excellent solvent. The root does not impart either taste or smell to water distilled from it. According to Gehlen, it contains 6.15 per cent. of a peculiar principle to which the name of *senegin* has been given, 7.5 of a soft resin, 26.85 of a sweetish and somewhat acrid extractive matter, 9.5 of gum with a little albumen, and 46.0 of lignin. *Senegin*, which has been supposed to be the active principle, is obtained by treating the alcoholic extract of the root successively with ether and water, which dissolve the sof resin and extractive, and leave the substance in question. This should be well washed with water. When dried it is translucent, brown, hard, and brittle. It has an acrid taste, which is especially sensible in the fauces, in this respect resembling that of seneka itself. It is more soluble in diluted than in concentrated alcohol, is insoluble in ether and the oils, and when quite pure is insoluble in water. When associated, however, with the other principles of the root, it is in part dissolved by the last mentioned fluid. Hence the extractive matter has an acrid taste, and the decoction of seneka is active. It is hardly probable that the senegin, as above obtained, is completely isolated. M. Peschier of Geneva obtained from the root a substance which he supposed to be alkaline, and to exist combined with a peculiar acid; but his experiments require confirmation. M. Feneulle of Cambray obtained 1. a pale yellow colouring matter, 2. a bitter substance, 3. gum, 4. pectic acid, 5. albumen, 6. volatile oil, 7. fixed oil, 8. saline and earthy matters. To M. Dulong d'Astafort the root yielded a peculiar alkaline principle, resin, gummy matter, a colouring matter analogous to wax, a yellow colouring matter, a substance reddened by the action of sulphuric acid, pectic acid, and salts. Still more recently an analysis by M. Folki presented the following results; viz. a thick oil in part volatile, free gallic acid, wax, an acrid principle, a yellow colouring matter, an azotized matter, and various salts.

The roots of the *Panax quinquefolium* or ginseng are frequently mixed with the seneka, but are easily distinguishable by their shape and taste.

Medical Properties and Uses. Seneka is a stimulating expectorant and diuretic, and in large doses proves emetic and cathartic. It appears indeed to excite more or less all the secretions, proving occasionally diaphoretic and emmenagogue, and increasing the flow of saliva. Its action, however, is more especially directed to the lungs; and its expectorant virtues are those for which it is chiefly employed. It was introduced into practice about a century ago by Dr. Tennant of Virginia, who recommended it as a cure for the bite of the rattlesnake and in various pectoral complaints. As an expectorant it is employed in cases not attended with inflammatory action, or in which the inflammation has in great measure been subdued. It is peculiarly useful in chronic catarrh, humoral asthma, the secondary stages of croup, and in peripneumonia notha after sufficient depletion. By Dr. Archer of Maryland it was recommended in the early stages of croup; but under these circumstances it is now seldom given unless in combination with squill and an antimonial, as in the *Mel Scillæ Compositum.* Employed so as to purge and vomit it has proved useful in rheumatism; and some cases of dropsy are said to have been cured by it. Amenorrhœa also is among the complaints for which it has been recommended.

The dose of powdered seneka is from ten to twenty grains; but the form of decoction is that in which the medicine is most conveniently administered. (See *Decoctum Senegæ.*) There is an officinal syrup; and an extract and tincture may be prepared, though neither is much employed.

Cassia. See CASSIA FISTULA.

The plants which yield senna belong to the genus Cassia, of which several species contribute to furnish the drug. These were confounded together by Linnæus in a single species, which he named Cassia Senna. Since his time the subject has been more thoroughly investigated, especially by Delile, who accompanied the French expedition to Egypt, and had an opportunity of examining the plant in its native country. Botanists at present distinguish at least three species, the C. acutifolia, the C. obovata, and the C. elongata, on each of which we shall offer a few observations.

2. *Cassia acutifolia.* Delile, *Flore d'Egypte*, lxxv. tab. 27. f. 1. This is a small undershrub, from two to three feet high, with a straight, woody, branching, whitish stem. The leaves are pinnate, alternately placed upon the stem, and have at their base two small narrow pointed stipules. The leaflets, of which four or five pairs belong to each leaf, are almost sessile, oval lanceolate, acute, oblique at their base, nerved, from half an inch to an inch in length, and of a yellowish-green colour. The flowers are yellow, and arranged in axillary spikes. The fruit is a flat, elliptical, obtuse, membranous, smooth, grayish-brown, bivalvular legume, about an inch long and half an inch broad, scarcely if at all curved, and divided into six or seven cells, each containing a hard, heart-shaped, ash-coloured seed. The C. acutifolia grows wild in great abundance in Upper Egypt near Sienne, in Nubia, Sennaar, and probably in other parts of Africa having similar qualities of soil and climate. It is this species that furnishes the Tripoli senna, and the greater part of that variety known in commerce by the title of Alexandria senna.

2. *Cassia obovata.* Colladon, *Monographie des Casses*, p. 92. tab. 15. fig. a.; De Cand., *Prodrom.*, ii. 492. The stem of this species is rather shorter than that of the C. acutifolia, rising to the height of only a foot and a half. The leaves have from five to seven pairs of leaflets, which are obovate, very obtuse, sometimes mucronate, in other respects similar to those of the preceding species. The flowers are in axillary spikes, of which the peduncles are longer than the leaves of the plant. The legumes are very much compressed, curved almost into the kidney form, of a greenish-brown colour

and covered with a very short down, which is perceptible only by the aid of a magnifying glass. They contain from eight to ten seeds. This plant, which according to M. Merat is annual, grows wild in Syria, Egypt, and Senegal; and is said to have been cultivated successfully in Italy, Spain, and the West Indies. It yields the variety of senna called in Europe Aleppo senna, and contributes to the packages of the Alexandrian.

3. *Cassia elongata.* Lemaire, *Journ. de Pharm.*, vii. 345; Fée, *Journ. de Chim. Med.*, vi. 232. This name was conferred by M. Lemaire upon the plant from which the India senna of commerce is derived. The botanical description was completed by M. Fée, from dried specimens of the leaves and fruit found by him in unassorted parcels of this variety of senna. Each leaf has five pairs of leaflets. These are elongated, acute, thin and flexible, obscurely mucronate, oblique, and with very short petioles; which are somewhat swollen, but not glandular. The most striking characteristic of the leaflet is its length, which varies from an inch to twenty lines. Its breadth is from three to five lines. The legumes are thin, shining, smooth, a little curved, mucronate and very obtuse at the summit, of a greenish-olive colour towards the edges, and blackish in the centre. They contain from five to seven irregular heart-shaped seeds. This species has not yet been examined by botanists in its native state. It is inferred, however, from the sources whence the variety of senna which it furnishes is brought, that it grows in the southern parts of Arabia.

Besides the three species of senna plants above described, a fourth is mentioned by some authors—the *C. lanceolata*—so named by Forskhal, who found it growing in the deserts of Arabia. Some difference, however, of opinion exists as to the justice of its claims to the rank of a distinct species. De Candolle considers it only a variety of the C. acutifolia, from the ordinary form of which it differs chiefly in having leaflets with glandular petioles. It has been supposed by some to be the source of the India and Mocha senna; but the leaflets in this variety are much longer than those of the C. lanceolata, from which they differ also in having no glands. Niebuhr informs us that he found the Alexandria senna growing in the Arabian territory of *Abuarish*, whence it is taken by the Arabs to Mecca and Jedda. This is probably the C. lanceolata of Forskhal.

Commercial History. Several varieties of this valuable drug are known in commerce. Of these we receive three only in America, the Alexandria, the Tripoli, and the India senna.

1. *Alexandria Senna.* Though the name of this variety is derived from the Egyptian port at which it is shipped, it is in fact gathered very far in the interior of the country. The Alexandria senna does not consist exclusively of the product of one species of Cassia. The history of its preparation is not destitute of interest. The senna plants of Upper Egypt yield two crops annually, one in spring and the other in autumn. They are gathered chiefly in the country beyond Sienne. The natives cut the plants, and having dried them in the sun, strip off the leaves and pods which they pack in bales, and send to Boulac, in the vicinity of Cairo, the great entrepot for this article of Egyptian commerce. This senna from Upper Egypt, consisting chiefly though not exclusively of the product of the C. acutifolia, is here mixed with the leaflets of the C. obovata, brought from other parts of Egypt, and even from Syria, and with the leaves of the *Cynanchum oleæfolium*, known commonly by the name of *argel* or *arguel.* A small portion of Mocha or Arabian senna is also probably added; and it is said that the leaves of the *Colutea arborescens* and *Coriaria myrtifolia* have been occasionally found in the parcels which reach the European market. Accord-

ing to M. Royer, the proportions in which the three chief constituents of this mixture are added together, are five parts of the C. acutifolia, three of the C. obovata, and two of Cynanchum. Thus prepared, the senna is again packed in bales, and transmitted to Alexandria. It is by no means improbable that a similar mixture is effected in this place of the C. acutifolia from Tripoli with the C. obovata from Syria. The Alexandria senna is often called in the French pharmaceutic works *séné de la palthe*, a name derived from an impost formerly laid upon it by the Ottoman Porte. If a parcel of this commercial variety of senna be carefully examined, it will be found to consist of the following ingredients:—1. The leaflets of the C. acutifolia, characterized by their acute pointed form, and their length always less than an inch; 2. the leaflets of the C. obovata, known by their rounded very obtuse summit, which is sometimes furnished with a small projecting point, and by their gradual diminution in breadth towards their base; 3. the pods, broken leafstalks, and fine fragments of other parts of one or both of these species; 4. the leaves of the Cynanchum oleæfolium, which are distinguishable by their length, almost always more than an inch, their greater thickness and firmness, the absence of any visible lateral nerves on their under surface, their somewhat lighter colour, and the regularity of their base. In this last character they strikingly differ from the genuine senna leaflets, which, from whatever species derived, are always marked by obliquity at their base, one side being inserted in the petiole at a point somewhat lower than the other, and at a different angle. The discrimination between this and the other ingredients is a matter of some consequence, as the cynanchum must be considered an adulteration. It is said by the French writers to occasion hypercatharsis and much irritation of the bowels. Besides the above constituents of Alexandria senna, it occasionally contains leaflets of genuine senna, much longer than those of the acutifolia or obovata, equalling in this respect the cynanchum, which they also somewhat resemble in form. They may be distinguished however by their greater thinness, the distinctness of their lateral nerves, and the irregularity of their base. They are probably, as before stated, the product of the C. elongata, and are brought to Egypt from Mocha in Arabia. The Alexandria senna sometimes comes to our market with very few leaves of the obovate senna and Cynanchum, and is then probably a portion of the product brought directly to Alexandria from Upper Egypt, without having undergone any intermixture at Boulac or other intervening place.

2. *Tripoli Senna.* It has been customary in England and this country to consider the Tripoli senna as very impure; and Paris expressly states, that it contains a much larger proportion than the Alexandrian of cynanchum and other adulterations. This, however, is a mistake, which has probably arisen from the inferior price commanded by this variety; and it is not uncommon to class indiscriminately together under this name all the least valuable parcels of the drug. The fact is, that the genuine Tripoli senna consists exclusively of the product of the C. acutifolia, containing neither the obovate senna nor the leaves of Cynanchum, and generally free even from the pods of the first mentioned species. The leaflets however are much broken up; and it is probably on this account that the variety is less esteemed than the Alexandrian. The aspect given to it by this state of comminution, and by the uniformity of its constitution, enables the eye at once to distinguish it from the other varieties of senna. The leaflets of the Tripoli senna, though undoubtedly derived from the C. acutifolia, differ in some respects from those of the same species contained in the Alexandrian. They are shorter, less acute, thinner, and more fragile; and their nerves are much less

distinct. From these characters of the Tripoli senna, there is good reason to believe, that the plant from which it is derived grows in a different region from the Egyptian, and in one less favourable to its full development. The general opinion is, that it is brought from Sennaar and Nubia in caravans across the desert, and receives its name from Tripoli simply as its place of export; but it is reasonably asked by M. Fée, how it could be afforded at a cheaper price than the Alexandrian, if thus brought on the backs of camels a distance of eight hundred leagues through the desert; and why, moreover, it should be unmixed with the obovate senna, if gathered in regions neighbouring to those from which the other variety is transmitted, which is known even when first gathered to contain a portion of this species. This author is of the opinion that the Tripoli senna grows upon the Mediterranean coast of Africa, in the vicinity of that city.

3. *India Senna.* This variety is in Europe sometimes called Mocha senna, and is identical with an article recently introduced into French commerce under the name of Senegambia senna, said to be derived from the western coast of Africa. It usually contains, besides the leaflets, considerable quantities of the pod, and of the petioles or leafstalks. The leaflets are all of the same character, and are evidently the product of the same plant. The eye is at once struck by their great length and comparative narrowness, so that no difficulty can be experienced in distinguishing this variety. The pike-like shape of the leaflet has given rise to the name of *séné de la pique*, by which it is known in French Pharmacy. It has been already stated that the title of C. elongata has been conferred upon the species from which it is derived. Though denominated India senna, and certainly imported from Calcutta and perhaps other ports of Hindostan, it appears not to be the growth of that country. Ainslie informs us that senna grows abundantly in India; but that it is of the species with obtuse leaves, and is not held in high estimation. A better sort, distinguished by its pointed leaves, is taken to India from Mocha, and extensively consumed. This is undoubtedly identical with that which we obtain from India, and of which the native country is Arabia Felix. It is said by Ainslie that the Arabian senna plant has been recently introduced into the South of India and pronises to succeed.

The senna of the Mediterranean is brought to our markets chiefly from Marseilles. The India or Mocha variety comes either directly from Calcutta, or by the route of London, where it is purchased at the East India Company's sales.

Commercial senna is prepared for use by picking out the leaflets, and rejecting the leafstalks, the small fragments, and the leaves of other plants. The pods are also rejected by some apothecaries; but they appear to possess he cathartic virtue to a considerable extent, if not equally with the leaves; nd, though not adopted by the American or British Pharmacopœias, are recognised as officinal in the Paris Codex.

Properties. The odour of senna is faint and sickly; the taste slightly itter, sweetish, and nauseous. Water and alcohol extract its active princiles. The leaves yield about one-third of their weight to boiling water, one int of which is requisite to exhaust the strength of an ounce of the medine. The infusion is of a deep reddish-brown colour, and preserves the lour and taste of the leaves. When exposed to the air for a short time, it eposites a yellowish insoluble precipitate, supposed to result from the union extractive matter with oxygen. The nature of this precipitate, however, not well understood. Decoction also produces some change in the principles of senna, by which its medicinal virtues are impaired. To diluted alcohol it imparts the same reddish-brown colour as to water; but rectified alcohol and ether digested upon the powdered leaves become of a deep olive-green. The analysis of senna by MM. Lassaigne and Feneulle furnished the following results. The leaves contain—1. a peculiar principle called cathartin; 2. chlorophylle or the green colouring matter of leaves; 3. a fixed oil; 4. a small quantity of volatile oil; 5. albumen; 6. a yellow colouring matter; 7. mucilage; 8. salts of the vegetable acids, viz. malate and tartrate of lime and acetate of potassa; and 9. mineral salts. The pods are composed of the same principles, with the exception of the chlorophylle, the place of which is supplied by a peculiar colouring matter. (*Journ. de Pharm.* vii. 548. *and* ix. 58.) Of these constituents, the most interesting and important is the *cathartin*, which is said to be the active principle of senna, and derived its name from this circumstance. It is an uncrystallizable substance, having a peculiar smell, a bitter, nauseous taste, and a reddish-yellow colour; is soluble in every proportion in water and alcohol, but insoluble in ether; and in its dry state attracts moisture from the air. It is prepared in the following manner. To a filtered decoction of senna the solution of acetate of lead is added; and the precipitate which forms is separated. A stream of hydrosulphuric acid (sulphuretted hydrogen) is then made to pass through the liquor in order to precipitate the lead, and the sulphuret produced is removed by filtration. The liquid is now evaporated to the consistence of an extract; the product is treated with rectified alcohol; and the alcoholic solution is evaporated. To the extract thus obtained sulphuric acid diluted with alcohol is added, in order to decompose the acetate of potassa which it contains; the sulphate of potassa is separated by filtration; the excess of sulphuric acid by the acetate of lead; the excess of acetate of lead by hydrosulphuric acid; and the sulphuret of lead by another filtration. The liquid being now evaporated yields *cathartin.*

Incompatibles. Many substances afford precipitates with the infusion of senna; but it by no means follows that they are all medicinally incompatible; as they may remove ingredients which have no influence upon the system, and leave the active principles unaffected. Cathartin is precipitated by the infusion of galls and probably other astringents, and by the solution of subacetate of lead. The acetate of lead and tartarized antimony, which disturb the infusion of senna, have no effect upon the solution of this principle.

Medical Properties and Uses. Senna was first used as a medicine by the Arabians. It was noticed in their writings so early as the ninth century; and the name itself is Arabic. It is a prompt, efficient, and very safe purgative, well calculated for fevers and febrile complaints, and other cases in which a decided but not violent impression is desired, An objection sometimes urged against it is that it is apt to produce severe griping pain in the bowels. This effect, however, may be obviated by combining with the senna some aromatic and some one of the alkaline salts, especially the supertartrate of potassa, tartrate of potassa, or sulphate of magnesia. The explanation which attributes the griping property to the oxidized extractive, and its prevention by the neutral salts to their influence in promoting the solubility of this substance, is not entirely satisfactory. The purgative effect o senna is considerably increased by combination with bitters, a fact whicl was noticed by Cullen, and has been abundantly confirmed by the experi ence of others. The decoction of guaiac is said to exert a similar influence The dose of senna in powder is from half a drachm to a drachm; but it bulk renders it of inconvenient administration; and it is not often prescribe in this state. Besides, the powder is said to undergo decomposition, and t become mouldy on exposure to a damp air. The form of infusion is almost universally preferred. (See *Infusum Sennæ.*) The medicine is sometimes used in the form of confection and of tincture.

SERPENTARIA. *U.S.*

Virginia Snakeroot.

"Aristolochia serpentaria. Radix. *The root.*" *U.S.*

Off. Syn. SERPENTARIÆ RADIX. Aristolochia Serpentaria. Radix. *Lond.;* ARISTOLOCHIÆ SERPENTARIÆ RADIX. *Ed.;* ARISTOLOCHIA SERPENTARIA. Radix. *Dub.*

Serpentaire de Virginie, *Fr.;* Virginianische Schlangenwurzel, *Germ.;* Serpentaria Virginiana, *Ital., Span.*

ARISTOLOCHIA. *Sex. Syst.* Gynandria Hexandria.—*Nat. Ord.* Aristolochiæ.

Gen. Ch. *Calyx* none. *Corolla* one-petaled, ligulate, ventricose at the base. *Capsule* six-celled, many-seeded, inferior. *Willd.*

Numerous species of Aristolochia have been employed in medicine. The roots of all of them are tonic and stimulant, and from their supposed possession of emmenagogue properties, have given origin to the name of the genus. The *A. Clematitis*, *A. longa*, *A. rotunda*, and *A. Pistolochia*, are still retained in many officinal catalogues of the continent of Europe, where they are indigenous. The root of the *A. Clematitis* is very long, cylindrical, as thick as a goose quill or thicker, variously contorted, beset with the remains of the stems and radicles, of a grayish-brown colour, a strong peculiar odour, and an acrid bitter taste; that of the *A. longa* is spindleshaped, from a few inches to a foot in length, of the thickness of the thumb or more, fleshy, very brittle, grayish externally, brownish-yellow within, bitter, and of a strong disagreeable odour when fresh; that of the *A. rotunda* is tuberous, roundish, heavy, fleshy, brownish on the exterior, grayish-yellow internally, and similar to the preceding in odour and taste; that of the *A. Pistolochia* consists of numerous slender yellowish or brownish fibres attached to a common head, and possessed of an agreeable aromatic odour, with a taste bitter and somewhat acrid. Many species of Aristolochia growing in the West Indies, Mexico, and South America, have attracted attention for their medicinal properties, and some, like our own snakeroot, have acquired the reputation of antidotes for the bites of serpents. In the East Indies, the *A. Indica* is employed for similar purposes with the European and American species; and the Arabians are said by Forskhal to use the leaves of the *A. sempervirens* as a counter-poison. We have within the limits of the United States four species, of which three—the *A. Serpentaria*, *A. tomentosa*, and *A. hastata*—contribute indiscriminately to furnish the snakeroot of the shops, though one only, the *A. Serpentaria*, is admitted into the Pharmacopœia.

Aristolochia Serpentaria. Willd. *Sp. Plant.* iv. 159; Bigelow, *Am. Med. Bot.* iii. 82; Barton, *Med. Bot.* ii. 41. This species of Aristolochia is an herbaceous plant with a perennial root, which consists of numerous slender fibres proceeding from a short horizontal caudex. Several stems often rise from the same root. They are about eight or ten inches in height, slender, round, flexuose, jointed at irregular distances, and frequently of a reddish or purple colour at the base. The leaves are oblong cordate, acuminate, entire, of a pale yellowish-green colour, and supported on short petioles at the joints of the stem. The flowers proceed from the joints near the root, and stand singly on long, slender, round, jointed peduncles, which are sometimes furnished with one or two small scales, and bend downward so as nearly to bury the flower in the earth or decayed leaves. There is no calyx. The corolla is of a purple colour, monopetalous, tubular, swelling at the base, contracted and curved in the middle, and terminating in a labiate border with lanceolate lips. The anthers—six or twelve in number—are sessile, attached to the under part of the stigma, which is roundish, divided into six parts, and supported by a short fleshy style upon an oblong, angular, hairy, inferior germ. The fruit is an hexangular, six-celled capsule, containing several small flat seeds.

The plant grows in rich, shady woods, throughout the Middle, Southern, and Western States, abounding in the valley of the Ohio, and in the mountainous regions of our interior. It flowers in May and June. The root is collected in Western Pennsylvania and Virginia, in Ohio, Indiana, and Kentucky, and is brought to the eastern markets chiefly by the route of Wheeling and Pittsburg. As it reaches Philadelphia, it is usually in bales containing one hundred pounds, and is often mixed with the leaves and stems of the plant, and with dirt from which it has not been properly cleansed at the time of collection.

A. tomentosa. Nuttall, *Gen. of N. Am. Plants*, p. 199.—*A. hirsuta*, Muhl. *Catal.* p. 81. The stem of this species is twining, and ascends to the summit of the tallest trees. Its leaves are roundish cordate, and villous on the under surface; the peduncles solitary and without bractes; the corolla densely villous, with a three-cleft, greenish-yellow border, and an oblique gaping orifice, the margin of which is elevated, rugose, and dark purple, while the interior of the tube is white, spotted with purple. The stigmas are three, and the anthers immersed in the style. The plant grows abundantly throughout Louisiana, on the banks of the Mississippi, on the mountains of South Carolina, and probably in other parts of the Western and Southern States.

A. hastata. Nuttall, *Gen. of N. Am. Plants*, p. 200.—*A. sagittata.* Muhl. *Catal.* This species, if indeed it can be considered a distinct species, differs from the A. Serpentaria in having hastate, acute, somewhat cordate leaves, radical peduncles, and the lip of the corolla ovate. It flourishes on the banks of the Mississippi, in Carolina, and elsewhere.

The roots of the two latter species scarcely differ from those of the officinal plant, and are frequently mixed with them, as is evinced by the presence of the characteristic leaves of the *A. tomentosa* and *A. hastata* in the parcels brought into market. (See *Journ. of the Phil. Col. of Pharm.* vol. i. p. 264.)

Properties. Virginia snakeroot, as found in the shops, is in tufts of long, slender, frequently interlaced and brittle fibres, attached to a short, contorted, knotty head or caudex. The colour, which in the recent state is yellowish, becomes brown by time. That of the powder is grayish. The smell is strong, aromatic, and camphorous; the taste warm, very bitter, and also camphorous. The root yields all its virtues to water and to alcohol, producing with the former a yellowish-brown infusion, with the latter a bright greenish tincture, which is rendered turbid by the addition of water. Chevallier found in the root, volatile oil, a yellow bitter principle soluble in water and alcohol, resin, gum, starch, albumen, lignin, and various salts. Bucholz obtained from 1000 parts, 5 of a green fragrant volatile oil, 28.5 of a yellowish-green resin, 17 of extractive matter, 181 of gummy extract, 624 of lignin, and 144.5 of water. The active ingredients are probably the volatile oil, and the yellow bitter principle of Chevallier, which that chemist considers analogous to the extract of quassia called *quassin* by Dr. Thomson. The volatile oil passes over with water in distillation, rendering the liquid milky, and impregnating it with the peculiar odour of the root. Dr. Bigelow states that the liquid on standing deposites round the edges of its surface small crystals of camphor.

Dr. A. T. Thomson in his Dispensatory informs us that the roots of the *Collinsonia præcox*, the *C. scabra* of Pursh, are often mixed with those of *A. Serpentaria.* This is not the case with the drug as brought to the Philadelphia market; but the roots of the *Spigelia Marilandica* are sometimes found associated with it. They may be distinguished by the absence of the bitter taste, and when the stem and foliage are attached, by the peculiar character of these parts of the plant. (See *Spigelia.*)

Medical Properties and Uses. Serpentaria is a stimulant tonic, acting also as a diaphoretic or diuretic, according to the mode of its application. Too largely taken, it occasions nausea, griping pains in the bowels, sometimes vomiting and dysenteric tenesmus. It is admirably adapted to the treatment of typhoid fevers, whether idiopathic or symptomatic, when the system begins to feel the necessity for support, but is unable to bear active stimulation. In exanthematous diseases in which the eruption is tardy or has receded, and the grade of action is low, it is thought to be useful by promoting the cutaneous affection. It has also been highly recommended in intermittent fevers; and though itself generally inadequate to the cure of the complaint, often proves serviceable as an adjunct to Peruvian bark or the sulphate of quinia. With he same remedies it is frequently associated in the treatment of typhous diseases. It is sometimes given in dyspepsia, and is employed as a gargle in nalignant sorethroat.

The dose of the powdered root is from ten to thirty grains; but the infuion is almost always preferred. (See *Infusum Serpentariæ.*) The decocion or extract would be an improper form, as the volatile oil, upon which he virtues of the medicine partly depend, is dissipated by boiling.

OLEUM SESAMI. *U.S. Secondary.*

Benne Oil.

"Sesamum orientale. Seminum oleum. *The oil of the seeds.*" *U.S.*

Sesame, *Fr.;* Sesam, *Germ.;* Sesamo, *Ital.;* Ajonjoli, *Span.*

Sesamum. *Sex. Syst.* Didynamia Angiospermia.—*Nat. Ord.* Bignoniæ, *Juss.;* Pedalineæ, *R. Brown, Lindley.*

Gen. Ch. *Calyx* five parted. *Corolla* bell-shaped, five-cleft, with the lower lobe largest. *Stamens* five, the fifth a rudiment. *Stigma* lanceolate. *Capsule* four-celled, *Willd.*

Though the *Sesamum orientale* has been indicated by the United States Pharmacopœia as the medicinal plant, there is reason to believe that the *S. Indicum* is that cultivated in our Southern States; at least we have found plants raised in Philadelphia from seeds obtained from Georgia, to correspond more closely with the description of the latter, as given by Willdenow. We give the specific character of both.

Sesamum orientale. Willd. *Sp. Plant.* iii. 358; Rheed. *Hort. Malab.* ix. 54. "Leaves ovate, oblong, entire."

Sesamum Indicum. Willd. *Sp. Plant.* iii. 359; Curtis, *Bot. Mag.* vol. xli. t. 1688. "Leaves ovate-lanceolate, the inferior three-lobed, the superior undivided. Stem erect."

The benne plant of our Southern States is annual, with a branching stem, which rises four or five feet in height, and bears opposite, petiolate leaves, varying considerably in their shape. Those on the upper part of the plant are ovate-lanceolate, irregularly serrate, and pointed; those near the base three-lobed and sometimes ternate; and lobed leaves are not uncommon at all distances from the ground. The flowers are of a reddish-white colour, and stand solitarily upon short peduncles in the axils of the leaves. The fruit is an oblong capsule, containing small, oval, yellowish seeds.

These two species of Sesamum are natives of the East Indies, and have been cultivated from time immemorial in various parts of Asia and Africa. From the latter continent it is supposed that seeds were brought by the Negroes to our Southern States, where, as well as in the West Indies, one or both species are now cultivated to a considerable extent. It has been found that the plant above described will grow vigorously in the gardens so far north as Philadelphia.

The seeds are employed as food by the negroes, who parch them over the fire, boil them in broths, make them into puddings, and prepare them in various other modes. By expression they yield a fixed oil, which, as well as the leaves of the plant, has been introduced into the secondary catalogue of our national Pharmacopœia.

1. *Oil of Benne.* This is inodorous, of a bland sweetish taste, and will keep very long without becoming rancid. It bears some resemblance to olive oil in its properties, and may be used for similar purposes. It was known to the ancient Persians and Egyptians, and is highly esteemed by the modern Arabs, and other people of the East, both as food, and as an external application to promote softness of the skin. Like olive oil, it is laxative in large doses.

2. *Leaves.* These abound in a gummy matter, which they readily impart to water, forming a rich bland mucilage, much used in the Sourthern States as a drink in various complaints to which demulcents are applicable, as in cholera infantum, diarrhœa, dysentery, catarrh, and affections of the urinary passages. The remedy has attracted some attention further northward, and has been employed with favourable results by physicians in Philadelphia. One or two fresh leaves stirred about in half a pint of cool water, will soon render it sufficiently viscid. In their dried state they should be introduced into hot water. The leaves also serve for the preparation of emollient cataplasms.

SEVUM. *U.S.*

Suet.

"Ovis aries. Sevum curatum. *The prepared suet. U.S.*

Off. Syn. SEVUM PRÆPARATUM. *Lond.;* ADEPS OVILLUS. *Ed.;* ADEPS OVILLUS PRÆPARATUS. *Dub.*

Suif, Graisse de mouton, *Fr.;* Hammelstalg, *Germ.;* Grasse duro, *Ital.;* Sebo. *Span.*

Suet is the fat of the sheep taken chiefly from about the kidneys. The London and Dublin Colleges direct it to be prepared by cutting the fat into pieces, melting it with a moderate heat, and straining it through linen or flannel. In order to avoid too great a heat, the crude suet is sometimes purified by boiling it in a little water.

Mutton-suet is of a firmer consistence, and requires a higher temperature for its fusion than any other animal fat. It is very white, somewhat brittle, inodorous, of a bland taste, insoluble in water, and nearly so in alcohol. Boiling alcohol, however, dissolves it, and deposites it upon cooling. It consists, according to Chevreul, of stearin, elaïn, and a small proportion of hircin. For an account of the two first mentioned principles, the reader is referred to the article *Adeps*. *Hircin* is a liquid like elaïn, from which it differs in being much more soluble in alcohol, and in being converted into *hircic acid* by saponification. (See *Sapo.*)

Suet acquires by time an unpleasant smell, and becomes unfit for pharmaceutic purposes. It is employed exclusively to give a proper consistence to ointments and plasters.

Quassia. See QUASSIA.

Quassia Simaruba. Willd. *Sp. Plant.* ii. 568; Woodv. *Med. Bot.* p. 69. t. 203. As this plant is polygamous, it belongs properly to the genus Simaruba, separated by De Candolle from the Quassia (see *Quassia*); but ve follow the Pharmacopœias in considering it under its former title. It is tree of considerable height and thickness, having alternate branches, with bark, which in the old tree is black and somewhat furrowed, in the young s smooth, gray, and marked here and there with broad yellow spots. The eaves are alternate and abruptly pinnate, with a naked petiole to which the eaflets are alternately attached by short footstalks. The leaflets are nearly lliptical, on the upper surface smooth and of a deep green colour, on the nder whitish. The flowers are of a yellow colour, and are disposed in ng axillary panicles. In some descriptions they are stated to be monœ-ous, in others diœcious. According to Dr. Wright, the female flowers are never found at Jamaica on the same tree with the male. The number of stamens is ten.

The tree is found in the West Indies and Guyana. In Jamaica it is called the mountain damson. Dr. A. T. Thomson is mistaken in stating that it is a native of Carolina. The *Simaruba amara* of Aublet, which grows in Guyana, and has generally been considered identical with the *Q. Simaruba*, is believed by Hayne to be a distinct species. The bark of the root is the part employed, the wood itself being nearly tasteless and inert.

Simaruba bark is in long pieces, some inches in breadth, folded lengthwise, light, flexible, tenacious, very fibrous, externally of a light brownish-yellow colour, rough, warty, and marked with transverse ridges, internally of a pale yellow. It is without smell, and of a bitter taste. It readily imparts its virtues, at ordinary temperatures, to water and alcohol. The infusion is at least equally bitter with the decoction, which becomes turbid as it cools. Its constituents, according to M. Morin, are a bitter principle, supposed by him to be identical with *quassin*, a resinous matter, a volatile oil having the odour of benzoin, malic acid, gallic acid in very minute proportion, an ammoniacal salt, malate and oxalate of lime, some mineral salts, oxide of iron, silica, ulmin, and lignin.

Medical Properties and Uses. Simaruba possesses the same tonic properties as other simple bitters, and may be employed for the same purposes. It was introduced into France in the year 1713 from Guyana, where it had previously been used as a remedy for dysentery. In the treatment of this disease and of obstinate diarrhœa it afterwards obtained much credit in Europe; but Cullen was right in denying to it any specific control over these complaints. It operates simply as a tonic; and, though it may be occasionally beneficial in relaxed and debilitated states of the alimentary canal, it would do much harm if indiscriminately prescribed in dysenteric cases.

On account of its difficult pulverization, it is seldom given in substance. The best mode of administration is by infusion. (See *Infusum Simaroubæ.*) The dose is from a scruple to a drachm.

Gen. Ch. Calyx spreading. *Corolla* with straight claws. *Glands* between the shorter stamens and pistil, and between the longer stamens and calyx. *Willd.*

Sinapis nigra. Willd. *Sp. Plant.* iii. 555; Woodv. *Med. Bot.* p. 403. t. 146. Common or black mustard is an annual plant, with a stem three or four feet in height, divided and subdivided into numerous spreading branches. The leaves are petiolate, and variously shaped. Those near the root are large, rough, lyrate-pinnate, and unequally toothed; those higher on the stem are smooth and less lobed; and the uppermost are entire, narrow, smooth, and dependent. The flowers are small, yellow, with a coloured calyx, and stand closely together upon peduncles at the upper part of the branches. The pods are smooth, erect, nearly parallel with the branches, quadrangular, furnished with a short beak, and occupied by numerous seeds.

Sinapis alba. Willd. *Sp. Plant.* iii. 555; Smith, *Flor. Brit.* 721. The white mustard is also an annual plant. It is rather smaller than the preceding species. The lower leaves are deeply pinnatifid, the upper sublyrate, and all irregularly toothed, rugged with stiff hairs on both sides, and of a pale green colour. The flowers are in racemes, with yellow petals, and linear, green, calycine leaflets. The pods are spreading, bristly, rugged, roundish, swelling in the position of the seeds, ribbed, and provided with a very long ensiform beak.

Both plants are natives of Europe and cultivated in our culinary gardens; and the *S. nigra* has become naturalized in some parts of this country. Their flowers appear in June. The seeds are kept in the shops both whole and in the state of very fine powder, as prepared by the manufacturers for the table.

The *black mustard seeds* are small, globular, of a deep brown colour, slightly rugose on the surface, and internally yellow. In the entire state they are inodorous, but have a distinct smell in powder, and when rubbed with water or vinegar exhale a strong pungent odour, sufficient in some instances to excite a flow of tears. Their taste is bitterish, hot, and pungent, but not permanent. The *seeds of the white mustard* are much larger, of a yellowish colour, and less pungent taste. Both afford a yellow powder, which has a somewhat unctuous appearance, and cakes when compressed. Their skin contains a mucilaginous substance, which is extracted by boiling water, and abounds most in the white. When bruised or powdered they impart their active properties wholly to water, but in a very slight degree to alcohol. They yield upon pressure a fixed oil, of a greenish-yellow colour, little smell, and a mild not unpleasant taste; and the portion which remains is even more pungent than the unpressed seed. When black mustard seeds are distilled with water they afford a yellow volatile oil, soluble in alcohol and water, of an exceedingly pungent odour, an acrid and burning taste, containing a portion of sulphur, and capable, when applied to the skin, of producing very speedy vesication. Guibourt conjectured, and Robiquet and Boutron have proved, that this oil does not exist ready formed in the seeds, but is produced by the action of water. Hence the absence or very slight degree of odour in the seeds when bruised in a perfectly dry state, and their great pungency when water is added. It will probably be found that a principle exists in black mustard seed, containing sulphur as a constituent, which is converted into volatile oil by the agency of this fluid. MM. Robiquet and Boutron were unable to procure any volatile oil from he white mustard seeds. The active properties of these they found to depend n a fixed principle, not existing in the seeds, but developed, as the volaile oil in the former case, by the action of water or other agent. The ingrelient of the seeds which is converted into this acrid principle, they believe o be the *sulpho-sinapisin* discovered originally by MM. Henry the younger nd Garot in the oil of white mustard, afterwards found in the seeds themelves. Their reason for this belief is that mustard which has been preiously deprived of this ingredient, is incapable of developing the acrid rinciple. As the white mustard contains none of that substance which ffords the volatile oil when water is applied, so the black mustard contains ttle or none of the *sulpho-sinapisin* which in the former is converted by milar means into the active principle. The two varieties, therefore, differ essentially in their constitution, though it is probable that their respective characteristic ingredients are closely analogous, as they both contain sulphur. *Sulpho-sinapisin* is an interesting compound, as affording an instance of a proximate vegetable principle having sulphur as a constituent. Its other elements are carbon, hydrogen, oxygen, and nitrogen. It was at first thought by MM. Henry and Garot to be an acid, but has since been acknowledged to be a neutral substance. It is white, crystallizable, soluble in water and alcohol, producing a yellow solution, without smell, and of a taste analogous to that of mustard. (*Journ. de Pharm. Janv.* 1831.)

From the experiments of MM. Troupeau and Blanc, it appears that vinegar diminishes the irritating property of black mustard; and that a mixture of the powder with concentrated acetic acid in certain proportions is quite inert when applied to the skin, though either separately is capable of exciting severe inflammation. The same result does not appear to have been obtained with the white mustard seed. (*Archives Generales. Sept.* 1830.)

Medical Properties and Uses. Mustard seeds swallowed whole operate as a laxative, and have recently enjoyed great popularity as a remedy in dyspepsia, and in other complaints attended with torpid bowels and deficient excitement. The white seeds are preferred, and are taken in the dose of a tablespoonful once or twice a day, mixed with molasses, or previously softened and rendered mucilaginous by immersion in hot water. They probably act by mechanically stimulating the bowels. The bruised seeds or powder, in the quantity of a large teaspoonful, operate as an emetic. Mustard in this state is applicable to cases of great torpor of stomach, especially that resulting from narcotic poisons. It rouses the gastric susceptibility and facilitates the action of other emetics. In smaller quantities it is useful as a safe stimulant of the digestive organs; and, as it is frequently determined to the kidneys, has been usefully employed in dropsy. Whey made by boiling half an ounce of the bruised seeds or powder in a pint of milk, and straining, is a convenient form for administration. It may be given in the dose of a wineglassful repeated several times a day. But mustard is most valuable as a rubefacient. Mixed with water in the form of a cataplasm, and applied to the skin, it very soon produces redness with a burning pain which in less than an hour usually becomes insupportable. When a speedy impression is not desired, especially when the sinapism is applied to the extremities, the powder should be diluted with an equal portion of rye meal or wheat flour. Care should be taken not to allow the application to continue too long, as vesication with obstinate ulceration, and even sphacelus may result. This caution is particularly necessary in cases where the patient is insensible, and the degree of pain can afford no criterion of the sufficiency of the action.

SODIUM.

Sodium.

Sodium, *Fr.;* Natronmetall, Natrium, *Germ.;* Sodio, *Ital.*, *Span.*

Sodium is a peculiar elementary body of a metallic nature, forming the basis of the alkali soda. It was discovered by Sir H. Davy in 1807, who obtained it in minute quantity by decomposing the alkali by the agency of galvanic electricity. It was afterwards procured in much larger quantities by Gay-Lussac and Thenard, by bringing the alkali in contact with iron turnings heated to whiteness. The iron became oxidized, and the metallic basis of the soda was liberated.

Sodium is a soft, malleable, sectile solid, of a silver-white colour. It possesses the metallic lustre in a high degree when protected from the action of the air, by which it is quickly tarnished and oxidized. Its sp. gr. is 0.97, fusing point about 200°, and equivalent number 23.3. Its chemical affinities resemble those of potassium, but are by no means so energetic. Like potassium it has a strong attraction for oxygen. When thrown upon cold water it instantly fuses into a globule without inflaming, and traverses the surface in different directions with rapidity; on hot water it inflames. In both cases the water is decomposed, hydrogen is liberated, and a solution of soda generated. It combines also with a larger proportion of oxygen than exists in soda, forming the peroxide of sodium. This oxide is always formed when the metal is burnt in the open air.

Sodium is present in a number of important medicinal preparations, and is briefly described in this place as an introduction to these compounds. Its protoxide only is salifiable, constituting the alkali soda, which, united to acids, gives rise to a numerous class of compounds, called salts of sodium or salts of soda. This oxide consists of one equiv. of sodium 23.3, and one of oxygen 8 = 31.3. United with one equiv. of water 9, it forms hydrate of soda (caustic soda,) weighing 40.3.

Sodium unites also with chlorine, forming chloride of sodium, or common salt, and with most of the other simple non-metallic bodies. The officinal combinations containing sodium, are the chloride of sodium, the acetate, borate, carbonate, bicarbonate, phosphate, sulphate, and sulphuret of soda, and the tartrate of potassa and soda. The description of most of these combinations will immediately follow; while the remainder, being included among the "Preparations," will be noticed, under their respective titles, in the second part of the work.

B.

SODÆ ACETAS. *U.S., Dub.*

Acetate of Soda.

Acétate de soude, *Fr.;* Essigsaures Natron, *Germ.;* Acetato di soda, *Ital.*

Acetate of soda is officinal only in the Dublin and United States Pharmacopœias. In the former work it is included among the "Preparations," in the latter, with greater propriety, in the catalogue of the Materia Medica; as the salt is made in considerable quantities by the manufacturing chemist in the process for purifying pyroligneous acid.

Preparation. The Dublin College obtains this salt by saturating carbonate of soda with distilled vinegar, and evaporating the filtered solution until it attains the sp. gr. 1. 276. As the solution cools crystals will form, which must be cautiously dried, and kept in well stopped bottles. In conducting the process, the crystallized carbonate of soda will be found to require about eleven times its weight of distilled vinegar for saturation.

The acetate of soda is prepared in large quantities by the manufacturers of pyroligneous acid, for the purpose of being decomposed, so as to yield strong acetic acid by the action of sulphuric acid. (See *Acidum Aceticum Empyreumaticum*, and *Acidum Aceticum.*) The first step is to add to the impure acid as much chalk as it is capable of decomposing at common temperatures, and then to boil the liquor, and complete the saturation with slaked lime. During the saturation a quantity of blackish scum arises, which must be carefully removed. In this way an acetate of lime is formed, which must be decomposed by the requisite quantity of sulphate of soda. By double decomposition there become formed acetate of soda, which remains in solution, and sulphate of lime, which precipitates, carrying down with it more or less of the tarry impurities. After the sulphate of lime has completely subsided, the solution of acetate of soda is decanted, and concentrated to a pellicle; when it is transferred to crystallizers, in which it cools and crystallizes in mass. The acetate, in this state, is very impure, being black and impregnated with much tar. It is purified by drying, submitting it to the igneous fusion, solution in water, filtration, and repeated crystallizations. Sometimes animal charcoal is used to free the crystals from colour.

Properties, &c. Acetate of soda is a white salt, crystallizing in long striated prisms, and possessing a sharp, bitterish, not disagreeable taste. Exposed to the air it effloresces slowly, and loses about forty per cent. of its weight. It is soluble in about three parts of cold water, and in twenty-four of alcohol. Subjected to heat, it undergoes first the aqueous and then the igneous fusion, and is finally decomposed. By the affusion of sulphuric acid it is decomposed, the acetic acid being liberated, and sulphate of soda formed. It consists, when crystallized, of one equiv. of acetic acid 51.48, one of soda, 31.3, and six of water $54=136.78$.

Medical Properties and Uses. Acetate of soda is diuretic, and possesses generally the same medical properties as the acetate of potassa, to which article the reader is referred. It is, however, more convenient for exhibition than the latter salt, as it is not deliquescent. The dose is from one to four scruples. Its only pharmaceutical use is to yield strong acetic acid by the action of sulphuric acid, and for this purpose it is employed in the United States Pharmacopœia.

* * *

SODÆ BORAS. *U.S.*

Borate of Soda.

Off. Syn. SODÆ SUBBORAS. *Lond.;* SUB-BORAS SODÆ. *Ed.;* SODÆ BORAS. BORAX. *Dub.*

Borax; Borate de soude, Borax, *Fr.;* Boraxsaures Natron, Borax, *Germ.;* Borace, *Ital.;* Borrax, *Span.;* Boorak, *Arab.*

Borax was known to the ancients, but its chemical nature was first ascertained by Geoffroy in 1732. It exists native, and may be obtained by artificial means. It occurs in small quantities in several localities in Europe, and in Peru in South America; but the demands of commerce are supplied almost exclusively by certain lakes, existing in Thibet and Persia, from which it is obtained by spontaneous evaporation. The impure borax concretes on the margins of these lakes, and is dug up in lumps, called in commerce *tincal* or *crude borax*. In this state it is in the form of crystalline masses, which are sometimes colourless, sometimes yellowish or greenish, and always covered with an earthy coating, greasy to the touch, and having the odour of soap. The greasy appearance is derived from a fatty matter, with which the excess of soda appears to be united. The crude borax, thus obtained in the interior, is transferred to the seaports of India, from which it is exported to this country packed in chests. Besides tincal, there is another commercial variety of borax, which comes from China, and which is partially refined. Both these kinds of borax require to be refined, before they are fit for use in medicine or the arts.

Purification. The method of refining borax was originally possessed as a secret by the Venetians and Dutch, but is now practised in several European countries. The process pursued in France, as reported by Robiquet and Marchand, is as follows. The tincal is placed in a large wooden vessel, and covered to the depth of three or four inches with water; in which state it is allowed to remain for five or six hours, agitating it from time to time. Slaked lime is now added, in the proportion of one part to four hundred of the impure salt; and the whole being mixed thoroughly, is allowed to remain at rest until the succeeding day. The salt is next separated by means of a sieve, the crystals being crumbled between the hands, and placed so as to drain. The object of this treatment is to separate the greasy matter, with which the lime forms an insoluble soap. The borax being drained is next dissolved, by the assistance of heat, in two and a half times its weight of water, and the solution treated with one-fiftieth of its weight of muriate of lime, and allowed to strain through a coarse bag. The filtration being completed, the liquor is concentrated by heat, and then run into wooden vessels, lined with lead, having the shape of an inverted quadrangular pyramid. If care be taken that the cooling proceeds very gradually, distinct crystals will be obtained, such as are found in commerce; otherwise, crystalline crusts will be formed. The washing with water in this process causes the loss of a minute portion only of the borax, the substances removed being a soapy matter, together with the sulphate and muriate of soda. The Chinese borax is purified in a similar manner, but being less impure than the common tincal, does not require to be washed. According to Berzelius, tincal, in the process of purification, loses half its weight; but according to Robiquet and Marchand, the loss is not nearly so great.

Preparation of Artificial Borax. In France of latter years borax has been made to a considerable extent by the direct combination of boracic acid with soda; and the same process is beginning to be employed by a few of our own manufacturing chemists. The acid made use of is imported from Italy, where it exists in solution in certain lakes, particularly in Tuscany. It is heated with water and carbonate of soda in excess, and the solution, after proper concentration, is allowed to crystallize in vessels lined with lead, as above described.

Properties. Borax is a white salt, generally crystallized in flattened hexahedral prisms terminated by triangular pyramids, and possessing a sweetish, feebly alkaline taste, and an alkaline reaction with test paper. It dissolves in twelve times it weight of cold, and twice its weight of boiling water. Exposed to the air, it effloresces slowly and slightly at the surface of the crystals, which become covered with a white powder. Subjected to a moderate heat it undergoes the aqueous fusion, swells considerably, and finally becomes a dry porous mass, with loss of half its weight. Above a red heat it melts into a limpid liquid, and, after cooling, concretes into a transparent solid, called *glass of borax*, which is very much used as a flux in assays with the blowpipe. According to Dr. Duncan, borax possesses the singular property of converting the mucilage of gum Arabic, of Iceland moss, or salep, into a gelatinous mass, without any adhesive property. It is decomposed by a majority of the acids, by potassa, and by the earthy and ammoniacal sulphates, muriates, phosphates, and fluates.

Borax has the property of rendering cream of tartar very soluble in water, and forms a combination with it, called *soluble cream of tartar*, which is sometimes used in medicine. This preparation is made by boiling six parts of cream of tartar and two of borax in sixteen of water for five minutes, allowing the solution to cool, and then filtering to separate some tartrate of lime. Soluble cream of tartar attracts moisture from the air, and is soluble in its own weight of cold, and half its weight of boiling water. A similar preparation may be made by substituting boracic acid for the borax; the proportions being four parts of cream of tartar to one of the acid. This combination is even more soluble than the other. It has not been well ascertained what is the nature of these compounds. Thenard has thrown out the suggestion, that the former consists of the tartrate of potassa and soda (Rochelle salt), and a combination of cream of tartar with boracic acid; and Berzelius inclines to the opinion, that in the latter the boracic acid acts the part of a base, and that the compound is a double salt, consisting of the tartrate of potassa and tartrate of boracic acid. Applying Berzelius's view to the former salt, it would consist of two double salts united together, namely the tartrate of potassa and soda, and the tartrate of potassa and boracic acid. According to the formula of the Paris Codex, soluble cream of tartar is made with boracic acid. Three parts of the acid are mixed with two parts of distilled water, and heated in a silver vessel, the mixture being stirred with a spatula. Twenty-one parts of cream of tartar are then added by small portions at a time, the mixture being constantly stirred. The whole completely liquefies, and, by a continuance of the heat until dryness is produced, passes into the state of powder. This is next thoroughly dried by the heat of a stove, and, after having been reduced to a very fine powder, is preserved in well stopped bottles.

Composition. Borax consists of two equiv. of boracic acid 69.8, and one of soda 31.3=101.1. As ordinarily crystallized it contains ten equiv. of water; but a variety of the salt exists, which crystallizes in octohedrons, and which contains only five equiv. of water. From the composition of borax in equivalents, it is evidently a *bi*borate, though generally called *sub*borate, on account of its possessing an alkaline reaction. This latter property arises from the feeble neutralizing power of boracic acid, which renders it inadequate to overcome the alkaline nature of so strong a base as soda.

Medical Properties and Uses. Borax is considered to be diuretic and emmenagogue, but is seldom used internally. Dr. Duncan quotes Wurzer for asserting that it is the best remedy that can be used in nephritic and calculous complaints, dependent on an excess of uric acid. It acts in such cases as an alkali, the boracic acid being displaced by the acid which may be met with in the stomach or urinary passages. The dose is from thirty to forty grains. Cream of tartar, rendered soluble by borax or boracic acid, is a convenient preparation, where it is desirable to administer large quantities of the former salt. The chief medical use, however, of borax, is as a detergent in aphthous affections of the mouth in children. When thus employed, it is generally applied in powder, mixed with sugar in the proportion of one part to seven, or rubbed up with honey. See *Mel Boracis*.

SODÆ CARBONAS VENALE.—BARILLA. *Dub.*

Commercial Carbonate of Soda.

Off. Syn. SODA IMPURA. *Lond.;* SUB-CARBONAS SODÆ IMPURUS. *Ed.*

Barilla; Soude du commerce, *Fr.;* Rohe Soda, *Germ.;* Soda impura, *Ital.;* Barilla, *Span.*

The impure carbonate of soda of commerce, or barilla, is introduced into the British Pharmacopœias, as the substance from which the pure carbonate is to be obtained by solution and crystallization. It has not a place in our national Pharmacopœia; as the purified carbonate, obtained by artificial means on a large scale by the manufacturing chemist, is sufficiently pure for medicinal use, and is the preparation found in our shops; the apothecary seldom or never resorting to any process for the purification of barilla.

The sources of the alkali soda are either natural or artificial. The natural sources are certain minerals which contain it in a carbonated state, and certain marine vegetables, which yield it by incineration; the artificial, are particular salts of soda which yield the alkali by chemical decomposition.

Native soda is found in different parts of the world; but chiefly in Egypt, in Hungary, and near Merida in the Republic of Columbia. It exists in these localities in solution in small lakes, from which it is extracted in consequence of the drying up of the water during the heats of summer. Native soda is called in commerce by the name of *natron*, and was formerly imported from Egypt for use in the arts; but for a number of years, the demands of commerce for this alkali have been supplied from other sources. The native soda of Egypt, called *trona* by the natives, proves on analysis to be a sesquicarbonate; while the South American is intermediate, in the proportion of its acid, between the Egyytian and artificial carbonate. None of these native sodas are important to the American chemist or druggist, as they are never imported into this country.

Soda of vegetable origin is derived from certain plants which grow on the the surface or borders of the sea, and is denominated either barilla or kelp, according to the particular character of the marine plants from which it is derived. *Barilla* is obtained from several vegetables, principally belonging to the genera *Salicornia* and *Salsola;* and the *Salsola soda* and *Salsola kali* are the species preferred. In Spain, Sicily, and some other countries, these plants are regularly cultivated for the purpose of yielding soda by their combustion. The plants, when mature, are cut down, dried, and burnt in excavations in the ground, about three feet deep, and four in diameter. The combustion is continued by the fresh addition of bundles of the dried plant, until the pit is filled with the ashes. These are found in the state of a semifused, hard, and compact saline mass, which is broken up into fragments by means of pickaxes, and thrown into commerce. *Kelp* is procured by the incineration of various kinds of sea-weeds, principally the algæ and fuci, which grow on the rocky coasts of many countries. The Orkney Islands, and the rocky coasts of Wales, Scotland, and Ireland, furnish large quantities of these weeds. The plants are allowed to ferment in heaps, then dried, and afterwards burnt to ashes in ovens, roughly made with brick or stone, and built in the ground. The alkali in the ashes melts, and forms the whole into one solid mass. When cold, it is broken up with iron instruments into large heavy masses, in which state it is found in commerce. Many thousand tons of kelp are thus annually made in Great Britain for the purposes of the arts.

An impure soda is obtained in a similar manner in France, under the name of *vareck.*

Properties. Barilla, when of good quality, is in hard, dry, porous, sonorous, grayish-blue masses, which become covered with a saline efflorescence after exposure to the air. It possesses an alkaline taste, but is inodorous, and should not emit any unpleasant smell on solution. It comes to this country principally from the Canary Islands. It contains from twenty-five to forty per cent. of real carbonated alkali, the residue being made up of sulphate of soda, sulphuret of sodium, common salt, carbonate of lime, alumina, silica, oxide of iron, and a small portion of charcoal which had escaped incineration.

Kelp is in hard compact masses, of a dark blue colour, and possessing a sulphureous odour, and an acrid, caustic taste. It is still less pure than barilla, containing only from three to eight per cent. of carbonated soda, the rest being made up of a large proportion of the sulphates of soda and potassa and the chlorides of potassium and sodium, and a small quantity of the iodide either of potassium or sodium. It is from kelp that iodine is most readily obtained. (See *Iodinum.*)

Preparation of the Artificial Soda of Commerce. Soda is obtained by chemical means, principally from the sulphate of soda, and the chloride of sodium or common salt. The methods pursued in Scotland for decomposing these salts are very well described by Mr. Steele, lecturer on chemistry in Glasgow, in a communication made to Dr. Duncan, from which we derive the following account. When the sulphate of soda is employed, 5 cwt. of the salt, 2 cwt. of saw-dust, 50 lbs. of lime, and a small quantity of iron-filings or borings are ground together, and then exposed to heat in a reverberatory furnace, until the mixture becomes pasty. During the calcination the sulphuric acid is decomposed; its oxygen combines with the carbon derived from the saw-dust, and forms carbonic acid, which unites with the soda; while the sulphur forms sulphurets with the lime and iron. The matter in this state is then transferred to large cisterns with double bottoms, where it is lixiviated to separate the soluble matter from the insoluble impurities. The ley obtained, consisting of a solution of carbonate of soda with a little sulphate of soda, is evaporated to dryness, and the dry mass subjected to a new treatment, precisely similar to that above described, with a view of decomposing the remains of the latter salt. The dry mass remaining after the second treatment consists of the soda, but is deficient in carbonic acid, in consequence of the strong heat to which it has been exposed. To supply this deficiency, the product is heated in a reverberatory furnace with a quantity of saw-dust, which, during its combustion, furnishes the necessary carbonic acid to the soda. The carbonate being thus completely formed, the matter from the furnace is again lixiviated, and the solution crystallized at a temperature which should not exceed 55°.

When soda is obtained from common salt, the process pursued is as follows. Saturated solutions of equal weights of common salt and pot or pearlash are mixed together and boiled to a pellicle. The common salt by solution in water becomes a muriate of soda, which, by double decomposion with the carbonate of potassa, generates carbonate of soda, and muriate of potassa in solution. This reaction having taken place, the solution is run into a cooler, and the muriate of potassa separates as chloride of potassium by priority of crystallization. The supernatant liquid containing the soda, somewhat deficient in carbonic acid owing to the deficiency of this acid in the potash, is now evaporated to dryness, and the dry mass calcined at a low red heat with saw-dust, to supply the deficient acid. It is then withdrawn from the furnace and lixiviated, and the solution crystallized at a temperature not exceeding 55°.

Sometimes soda is obtained from what are called *soaper's salts*, which are the saline matters remaining after the conversion of the alkali in kelp into hard soap. These salts consist of the sulphates and muriates of soda and potassa, and are treated in the same way as the unmixed sulphate of soda. The sulphate of soda in the mixture is of course converted into carbonate of soda, and by the operation of similar affinities, the sulphate of potassa passes into the state of a carbonate. The carbonate of potassa, as soon as formed, reacts upon the muriate of soda, and produces an additional portion of carbonate of soda. The muriate of potassa is consequently the only salt present in the soaper's salts, which remains unchanged in the process; and its quantity is somewhat increased by the decomposition of the common salt. (*Duncan, Edinb. Dispensatory.*)

The method of obtaining carbonate of soda by the decomposition of the salts of soda was first put in practice in France by Leblanc and Dizé, and has since been improved by other chemists. The process above detailed is that practised in Scotland, in which country large quantities of artificial carbonate of soda are made. The alkali, as obtained after the first calcination of the materials, is very impure, containing only from thirty-two to thirty-three per cent. of pure carbonate of soda, and may be considered as corresponding in quality to the barilla of commerce; but after being subjected to all the steps of the process, as above described, it may be considered as a pure carbonate of soda.

The carbonate of soda used in this country is chiefly imported from Scotland, and comes packed in hogsheads. The impure carbonate, in the form of barilla, is imported principally from the Canary Islands, and is consumed by the soap manufacturers. The different kinds of impure carbonate of soda of commerce, whether barilla or kelp, are exceedingly variable in composition; and as their value depends entirely on the quantity of real carbonated alkali which they contain, it becomes important to have a ready method of determining this quantity. The mode in which this is ascertained, by means of an instrument called an alkalimeter, is explained under another head. (See *Potassæ Carbonas Impurus.*)

Pharmaceutical Uses, &c. Barilla is never used in medicine, but is directed by the British Colleges for the purpose of obtaining from it the pure carbonate of soda. It is largely consumed in the arts, in the manufacture of soap and glass, and in some of the processes of dyeing.

◆

SODÆ CARBONAS. *U.S. Dub.*

Carbonate of Soda.

Off. Syn. SODÆ SUBCARBONAS. *Lond.;* SUB-CARBONAS SODÆ. *Ed.*

Carbonate de soude, *Fr.;* Kohlensaures Natron, *Germ.;* Carbonato di soda, *Ital.;* Carbonato de soda, *Span.*

The different British Colleges give directions for the preparation of this salt from barilla by solution and crystallization; but the framers of the United States Pharmacopœia have placed it more properly in the list of the Materia Medica, as a product obtained on a large scale by the manufacturing chemist, and not made by the apothecary.

The directions of the British Colleges for the purification of barilla do not materially differ. The *London* College takes a pound of the impure salt, boils it with four pints of distilled water for half an hour, and filters. The solution is then evaporated to two pints, and set aside to crystallize. The *Edinburgh* process is the same, with the exception that the quantity of water to be used is not specified. The *Dublin* College exhausts the barilla by boiling it with twice its weight of water for two or three successive times, and, having mixed the several solutions, evaporates to dryness. The dry mass is then dissolved in boiling water, and the solution evaporated until it acquires the sp. gr. 1.22; when it is exposed to a temperature about freezing, in order that it may crystallize. The crystals are then dried and kept in close bottles.

These processes for the purification of barilla are almost entirely superseded, in consequecce of the great perfection to which the artificial production of the carbonate of soda has been brought. It is this product, made on a large scale, that supplies our apothecaries with the carbonate of soda which they vend. The manner in which it is prepared is fully detailed under the preceding article. (See *Sodæ Carbonas Venale.*)

Properties. Carbonate of soda is a white efflorescent salt, possessing an alkaline, slightly caustic taste, and crystallizing usually in large rhomboidal prisms, which are opaque and powdery on the surface, but semitransparent within. It is exceedingly soluble in water and displays an alkaline reaction with tests. When heated it undergoes the aqueous fusion at a low temperature; and if the heat be continued it dries, and finally suffers the igneous fusion. The most usual impurities which it contains are sulphate of soda and common salt, which may be detected by converting the salt into a nitrate, and testing separate portions of this severally with the nitrates of baryta and silver. Carbonate of soda is incompatible with acids, acidulous salts, lime-water, muriate of ammonia, and earthy and metallic salts. It consists of one equiv. of carbonic acid 22.12, and one of soda 31.3=53.42. When fully crystallized it contains ten equivalents of water 90, giving as the number representing the crystallized salt 143.42. It is thus perceived that this salt, when perfectly crystallized, contains nearly two-thirds of its weight of water; but the actual quantity present in it as found in the shops, is very variable, being dependent on the extent to which it may have undergone efflorescence.

Medical Properties and Uses. Carbonate of soda is antacid and deobstruent. It is given principally in diseases attended with acidity of the stomach; such as gout, uric acid gravel, and certain forms of dyspepsia. It is more frequently exhibited than carbonate of potassa, as it is more easily taken, its taste being less acrid. It has also been recommended in hooping-cough, scrofula, and bronchocele. In the latter disease, Dr. Peschier of Geneva considers it more efficacious than the iodine itself. It is given in doses of from ten grains to half a drachm, either in powder, or in solution in some bitter infusion. In consequence of the variable state in which it exists in the shops, as to the amount of water of crystallization which it contains, it is not easy to designate the dose with precision. It is on this account, that the most convenient form of the salt for administration is in the dried state. (See *Sodæ Carbonas Exsiccatus.*) It is used in preparing the precipitated carbonate of iron.

SODÆ SULPHAS. *U. S., Lond., Dub.*

Sulphate of Soda.

Off. Syn. SULPHAS SODÆ. *Ed.*

Vitriolated soda, Glauber's salt; Sulfate de soude, *Fr.;* Schwefelsaures Natron, Glaubersalz, *Germ.;* Solfato di soda, *Ital.;* Sulfato de soda, Sal de Glaubero, *Span.*

This salt is included among the Preparations by the three British Colleges, a formula for obtaining it being given; and is placed also in the catalogue of the Materia Medica by the London and Edinburgh Colleges. In the United States Pharmacopœia, it is inserted only in the Materia Medica, where it properly stands as a substance obtained on a large scale.

Sulphate of soda, in small quantities, is extensively diffused in nature, and is obtained artificially in several chemical operations. It exists in solution in many mineral springs, among which may be mentioned those of Cheltenham and Carlsbad; its ingredients are present in sea-water; and it is found combined with sulphate of lime, constituting a distinct mineral. As an artificial product, it is formed in the processes for obtaining muriatic acid and chlorine, and in the preparation of muriate of ammonia, from sulphate of ammonia and common salt. (See *Acidum Muriaticum, Aqua Chlorinii,* and *Ammoniæ Murias.*) It may also be procured, under favourable circumstances, from sea-water.

Preparation. The British Colleges agree in obtaining sulphate of soda from the salt left after the distillation of muriatic acid. This residuary salt, as is explained under muriatic acid, is sulphate of soda; but it generally contains a slight excess of sulphuric acid, which must be neutralized or removed. The *London College* dissolves two pounds of the salt in two pints and a half of boiling water, and saturates the excess of acid with carbonate of soda. The solution is then evaporated to a pellicle, filtered, and set aside to crystallize. The supernatant liquor being poured off, the crystals are dried on blotting paper. The *Edinburgh College* dissolves the salt in water, the quantity not being specified, and adds to the solution powdered carbonate of lime to neutralize the excess of acid. The solution, after being allowed to stand until the precipitate subsides, is poured off clear, filtered through paper, and evaporated to the point of crystallization. In the *Dublin* Pharmacopœia, the salt is directed to be dissolved in a sufficient quantity of boiling water, and the solution, after filtration and due evaporation, is allowed to crystallize by slow cooling.

In the above processes, it is perceived that the London College converts the excess of acid in the residuary salt into an additional portion of sulphate of soda; while the Edinburgh College gets rid of the excess, by converting it into the insoluble sulphate of lime. The latter plan is considered the best, as the London process implies the expenditure of a more valuable, to obtain a less valuable salt. The Dublin process makes no provision for removing the excess of acid, and hence the sulphate of soda obtained is slightly acid.

The residuum of the process for obtaining chlorine by the action of sulphuric acid, water, and peroxide of manganese on common salt, is a mixture of sulphate of soda and sulphate of protoxide of manganese. We have not been able to find any detailed process for separating the sulphate of soda from this mixture; but we are informed by Mr. Parkes, that an establishment for this purpose in England was attended with complete success, and was only discontinued in consequence of the Government having forbidden the sale of the residuum in question. Considering the large quantities of this residuum, which are necessarily formed in preparing chloride of lime and other bleaching agents, it would seem worth the while of our manufacturing chemists to attempt its purification. The object would not be to furnish a salt for use in medicine, but to convert the sulphate of soda which might be obtained into the carbonate. (See *Sodæ Carbonas Venale.*) For this purpose, it would probably not require to be carefully purified.

In the process for obtaining muriate of ammonia from the sulphate and common salt, water is decomposed, and a double decomposition takes place, resulting in the formation of muriate of ammonia and sulphate of soda. The mode in which the two salts are afterwards separated is explained under the head of *muriate of ammonia.*

Since the chemical method of making carbonate of soda from the sulphate has been generally practised in France and England, the consumption of Glauber's salt has considerably increased, and its preparation has been an object of importance. In France, it is usually made by decomposing common salt by sulphuric acid, and in most instances the muriatic acid is allowed to escape. This is the same process with that of the British Colleges, only performed on a large scale. In Sweden sulphate of soda is made by double decomposition between sulphate of iron and common salt. In some of our Northern States, particularly Massachusetts, a portion of Glauber's salt is made from sea-water in the winter season. The circumstances under which it is formed, have been explained in a paper "On the preparation of Glauber's and Epsom Salt and Magnesia from Sea-water," by Mr. Daniel B. Smith, published in the fourth volume of the Journal of the Philadelphia College of Pharmacy, The constituents of a number of salts exist in sea-water; and in what binary order they may precipitate during evaporation, depends on the temperature. During the prevalence of rigorous cold, sulphate of soda is the least soluble salt which can be formed out of the acids and bases present, and accordingly separates in the form of crystals.

Properties. Sulphate of soda is a white salt, possessing a cooling, nauseous, bitter taste, and crystallizing with great facility in four-sided striated prisms, with dihedral summits. When recently prepared, it is beautifully transparent; but by exposure to the air it effloresces, and the crystals become covered with an opaque white powder. By long exposure it undergoes complete efflorescence, and falls to powder with loss of more than half its weight. It is soluble in about twice its weight of cold water, and in less than one-third of its weight at 91.5°, above which temperature, up to the boiling point, its solubility diminishes. Subjected to heat, it melts in its water of crystallization, then dries, and afterwards, by the application of a pretty strong heat, undergoes the igneous fusion. Occasionally it contains an excess of acid or alkali, which may be discovered by the use of litmus or turmeric paper. The presence of common salt may be detected by sulphate of silver; that of iron by ferrocyanate of potassa or tincture of galls. It is incompatible with carbonate of potassa, muriate of lime, the salts of baryta, nitrate of silver if the solutions be strong, and the acetate and subacetate of lead. It consists of one equiv. of sulphuric acid 40.1, one of soda 31.3, and ten of water 90=161.4.

Medical Properties and Uses. Sulphate of soda, in doses of from half an ounce to an ounce, is an efficient cathartic; in smaller doses largely diluted, an aperient and diuretic. When in an effloresced state, the dose must be reduced one-half. It is much less used than formerly, having been almost entirely superseded by sulphate of magnesia, which is less disagreeable to the palate. Its nauseous taste, however, may be readily disguised by the admixture of a little lemon-juice or cream of tartar. Sulphate of soda is the principal ingredient in the artificial *Cheltenham salts.* These consist of 120 grs. of sulphate of soda, 66 grs. of sulphate of magnesia, 10 grs. of muriate of soda, and half a grain of sulphate of iron, and constitute, according to Dr. Paris, a very efficacious purgative. The only use of sulphate of soda in the arts is to make carbonate of soda, and as an ingredient in some kinds of glass. It has no officinal preparations. B.

SODII CHLORIDUM. *U.S.*

Chloride of Sodium.

Off. Syn. SODÆ MURIAS. *Lond., Dub.;* MURIAS SODÆ. *Ed.*

Muriate of soda, Common salt; Chlorure de sodium, Hydro-chlorate de soude, Sel marin, *Fr.;* Salzsaures Natron, Kochsalz, *Germ.;* Salt, *Dan., Swed.;* Sal commune, *Ital.;* Sal, *Span.*

This mineral production, so necessary to the wants of mankind, is universally distributed over the globe, and is the most abundant of the native soluble salts. Most animals have an instinctive relish for it; and from its frequent presence in the solids and fluids of the animal economy, it may be viewed as performing an important part in nutrition and assimilation.

Natural State. Common salt exists in nature, either in the solid state or in solution. In the solid state, called rock salt, it is often found forming extensive beds, and even entire mountains, from which it is extracted in blocks or masses by mining operations. Its geological position is very constant, occurring almost invariably in secondary formations, associated with clay and gypsum. In solution it occurs in certain springs and lakes, and in the waters of the ocean. The principal salt-mines in the world are found in Poland, Hungary, and Russia; in various parts of Germany, particularly the Tyrol; in England, in the county of Cheshire; in Spain; in various parts of Asia and Africa; and in Peru, and other countries of South America. In the United States there are no salt-mines, but numerous saline springs, which either flow naturally, or are produced artificially by sinking shafts to various depths, in places where salt is known to exist. These are found principally in Missouri, Kentucky, Illinois, Ohio, Pennsylvania, Virginia, and New York. In the last mentioned State the springs are the most productive; the chief ones being situated at Salina, Montezuma, and Galen. In Virginia, an important salt region exists, extending fifteen miles on each side of the great Kanawha river. The salt works in this district were estimated in 1835 to have produced two millions of bushels of salt. Rock salt is always transparent or translucent; but it often exhibits various colours, such as red, yellow, brown, violet, blue, &c., which are supposed to be derived from iron and manganese.

Extraction. Mines of salt are worked in two ways. When the salt is pure, it is merely dug out in blocks and thrown into commerce. When impure, it is dissolved in water and extracted afterwards from the solution by evaporation. When the salt is naturally in solution, the mode of extraction depends upon the strength of the brine, and the temperature of the place where it is found. When the water contains from fourteen to fifteen per cent. of salt, it is extracted by evaporation in large iron boilers. If, however, it contains only two, three, four, or five per cent., the salt is obtained in a different manner. If the climate be warm it is procured by spontaneous evaporation, effected by the heat of the sun; if temperate, by a peculiar mode of spontaneous evaporation to be mentioned presently, and the subsequent application of artificial heat.

Sea-water is a weak saline solution, from which salt is often extracted by the agency of solar heat in warm countries. Salt thus obtained, is called *bay salt*. The extraction is conducted in Europe principally on the shores of the Mediterranean, the waters of which are salter than those of the open ocean. The mode in which it is performed is by letting in the sea-water into a kind of shallow dikes, lined with clay, and capable, after being filled, of being shut off from the sea. In this situation the heat of the sun gradually concentrates the water, and the salt is deposited. In temperate climates, weak brines are first concentrated in buildings, called *graduation houses*. These are rough wooden structures, open on the sides, ten or eleven yards high, five or six wide, and three or four hundred long, and containing an oblong pile of faggots somewhat smaller than the building itself. The brine is pumped up into troughs full of holes, placed above the faggots, upon which it is allowed to fall; and in its descent it becomes minutely divided. This operation, by greatly increasing the surface of the brine, promotes its evaporation; and being repeated several times, the solution is at last brought to the requisite degree of strength, to permit of its final concentration in iron boilers by artificial heat. Sometimes, to save fuel, the last concentration is performed by allowing the brine to trickle down a number of vertical ropes, on the surface of which the salt is deposited in the form of a crust.

Properties. Chloride of sodium is white, without odour, and of a peculiar taste, called saline. It is usually crystallized in cubes; but by hasty evaporation it often assumes the form of hollow quadrangular pyramids. When pure it undergoes no change in the air; but when contaminated with muriate of magnesia, as not unfrequently happens, it is rendered deliquescent. It dissolves in somewhat less than three times its weight of cold water, and is scarcely more soluble in boiling water. In weak alcohol it is very soluble, but sparingly so in absolute alcohol. Exposed to a gradually increasing heat, it first decrepitates from the presence of interstitial moisture, next melts, and finally volatilizes in white fumes without decomposition. It is decomposed by several of the acids, particularly the sulphuric and nitric, which disengage vapours of muriatic acid; by carbonate of potassa with the assistance of heat; and by the nitrate of silver and protoxide of mercury.

Several varieties of common salt are distinguished in commerce; as *stoved salt*, *fishery salt*, *bay salt*, &c.; but they are characterized by modifications in the size and compactness of the grains, rather than by any essential difference in composition.

Composition. Common salt, in its pure state, consists of one equiv. of chlorine 35.42, and one of sodium 23.3=58.72. It contains no water of crystallization. When in solution it is supposed to become a muriate of soda in consequence of the decomposition of water, the hydrogen and oxygen of which severally convert the chlorine and sodium into muriatic acid and soda. The common salt of commerce, besides pure chloride of sodium, contains, generally speaking, insoluble matter, and usually more or less of the muriates and sulphates of lime and magnesia. The muriate of lime is generally present in very small amount; but the muriate of magnesia sometimes amounts to 28 parts in 1000. Sulphate of lime is usually present, constituting variously from 1 part to 23 in 1000; and sulphate of magnesia is sometimes present and sometimes absent. To separate the earths, a boiling solution of carbonate of soda must be added, as long as any precipitate is formed. The earths will fall as carbonates, and must be separated by filtration, and muriate and sulphate of soda will remain in solution. The sulphate of soda may then be decomposed by the cautious addition of muriate of baryta, which will generate muriate of soda, and the insoluble sulphate of baryta.

Medical Properties and Uses. Chloride of sodium, in small doses, acts as a stimulant tonic; in larger doses, as a purgative. It certainly promotes digestion, and the almost universal animal appetency for it, proves it to be a salutary stimulus in health. When taken in larger quantities than usual with food, it is useful in some forms of dyspepsia, and by giving greater tone to the digestive organs in weakly children, may correct the disposition to generate worms. On the sudden occurrence of hæmoptysis, it is usefully resorted to as a styptic, in the dose of a teaspoonful, taken dry, and often proves successful in stopping the flow of blood. Externally applied in solution it is stimulant, and may be used either locally or generally. Locally it is sometimes employed as a fomentation in sprains and bruises; and as a general external application, it forms the salt water bath, a valuable remedy as a tonic and excitant in depraved conditions of the system, occurring especially in children, and supposed to be dependent on the scrofulous diathesis. It is frequently used as an ingredient in stimulating enemata. The dose, as a tonic, is from ten grains to a drachm; as a cathartic, though seldom used for this purpose, from half an ounce to an ounce. When employed as a clyster, it may be used in the amount of from one to two tablespoonfuls dissolved in a pint of water.

The uses of common salt in domestic economy as a condiment and antiseptic are well known. In agriculture it is sometimes used as a manure, and in the arts it is employed to prepare artificial soda and muriate of ammonia. In pharmacy it is used in the processes for obtaining muriatic acid, chlorine, calomel, and corrosive sublimate.

SOLIDAGO. *U.S. Secondary.*

Golden-rod.

"Solidago odora. Folia. *The leaves.*" *U. S.*

Solidago. *Sex. Syst.* Syngenesia Superflua.—*Nat. Ord.* Compositæ Corymbiferæ.

Gen. Ch. *Calyx* imbricated, scales closed. *Radial florets* about five, yellow. *Receptacle* naked, punctate. *Pappus* simple pilose. *Nuttall.*

This is a very abundant genus, including, according to Eaton's enumeration, upwards of sixty species belonging to this country. Of these the *S. odora* only is officinal. The *S. Virgaurea*, which is common to the United States and Europe, was formerly directed by the Dublin College; but was omitted in the last edition of their Pharmacopœia. It is astringent, and has been supposed to possess lithontriptic virtues.

Solidago odora. Willd. *Sp. Plant.* iii. 2061; Bigelow, *Am. Med. Bot.* i. 187. The *sweet-scented golden-rod* has a perennial creeping root, and a slender, erect, pubescent stem, which rises two or three feet in height. The leaves are sessile, linear lanceolate, entire, acute, rough at the margin, elsewhere smooth, and, according to Bigelow, covered with pellucid dots. The flowers are of a deep golden-yellow colour, and are arranged in a terminal, compound, panicled raceme, the branches of which spread almost horizontally, are each accompanied by a small leaf, and support the flowers on downy pedicels, which put forth from the upper side of the peduncle, and have small linear bractes at their base. The florets of the ray are ligulate, oblong, and obtuse; those of the disk funnel-shaped, with acute segments.

The plant grows in woods and fields throughout the United States, and is in flower from August to October. The leaves, which are the officinal portion, have a fragrant odour, and a warm, aromatic, agreeable taste. These properties depend on a volatile oil, which may be separated by distillation with water. It is of a pale greenish-yellow colour, and lighter than water.

Medical Properties and Uses. Golden-rod is aromatic, moderately stimulant and carminative, and like other substances of the same class, diaphoretic when given in warm infusion. It may be used to relieve pain arising from flatulence, to allay nausea, and to cover the taste or correct the operation of unpleasant or irritating medicines. For these purposes it may be given in infusion. The volatile oil dissolved in alcohol is employed in the Eastern States. According to Pursh, the dried flowers are used as a pleasant and wholesome substitute for common tea. W.

SPARTIUM. *U.S. Secondary.*

Broom.

" Spartium scoparium. Cacumina. *The tops.*" *U. S.*

Off. Syn. SPARTII CACUMINA. Spartium scoparium. Cacumina. *Lond.;* SPARTII SCOPARII SUMMITATES. *Ed.;* SPARTIUM SCOPARIUM. Cacumina. *Dub.*

Genet a balais, *Fr.;* Gemeine Besenginster, Pfriemén, *Germ.;* Scoparia, *Ital.;* Retama, *Span.*

Spartium. *Sex. Syst.* Diadelphia Decandria.—*Nat. Ord.* Leguminosæ.

Gen. Ch. *Stigma* longitudinal, villous above. *Filaments* adhering to the germen. *Calyx* produced downwards. *Willd.*

Spartium scoparium. Willd. *Sp. Plant.* iii. 933; Woodv. *Med. Bot.* p. 413. t. 150. This is a common European shrub, cultivated in our gardens, from three to eight feet high, with numerous straight, pentangular, bright-green, very flexible branches, and small, oblong, downy leaves, which are usually ternate, but on the upper part of the plant are sometimes simple. The flowers are numerous, papilionaceous, large, showy, of a golden-yellow colour, and supported solitarily upon short axillary peduncles. The seeds are contained in a compressed legume, which is hairy at the sutures.

The whole plant has a bitter nauseous taste, and when bruised, a strong peculiar odour. The tops of the branches are the officinal portion; but the seeds are also used, and possess similar virtues. Water and alcohol extract their active properties.

Medical Properties and Uses. Broom is diuretic and cathartic, and has been employed with some advantage in dropsical complaints, in which it was recommended by Mead, Cullen, and others. Cullen prescribed it in the form of decoction, made by boiling half an ounce of the fresh tops in a pint of water down to half a pint, of which he gave a fluidounce every hour till it operated by stool or urine. It is a domestic remedy in Great Britain, but is seldom used in this country.

SPIGELIA. *U. S.*

Pink-root.

"Spigelia Marilandica. Radix. *The root.*" *U. S.*

Off. Syn. SPIGELIÆ RADIX. Spigelia Marilandica. Radix. *Lond.;* SPIGELIÆ MARILANDICÆ RADIX. *Ed.;* SPIGELIA MARILANDICA. Radix. *Dub.*

Spigélie du Maryland, *Fr.;* Spigelie, *Germ.;* Spigelia, *Ital.*

SPIGELIA. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Gentianæ, *Juss.;* Spigeliaceæ, *Martius, Lindley.*

Gen. Ch. *Calyx* five-parted. *Corolla* funnel-shaped, border five-cleft, equal. *Capsule* didymous, two-celled, four-valved, many-seeded. *Nuttall.*

There are two species of Spigelia which have attracted attention as anthelmintics, the *S. anthelmintica* of South America and the West Indies, and the *S. Marilandica* of this country. The former is an annual plant, used only in the countries where it grows, the latter is much employed both in this country and in Europe.

Spigelia Marilandica. Willd. *Sp. Plant.* i. 825; Bigelow, *Am. Med. Bot.* i. 142; Barton, *Med. Bot.* ii. 75. The *Carolina pink* is an herbaceous plant with a perennial root, which sends off numerous fibrous branches. The stems, several of which rise from the same root, are simple, erect, four-sided, nearly smooth, and from twelve to twenty inches high. The leaves are opposite, sessile, ovate lanceolate, acuminate, entire, and smooth, with the veins and margins slightly pubescent. Each stem terminates in a spike, which leans to one side and supports from four to twelve flowers with very short peduncles. The calyx is persistent, with five long, subulate, slightly serrate leaves, reflexed in the ripe fruit. The corolla is funnel-shaped, and much longer than the calyx, with the tube inflated in the middle, and the border divided into five acute, spreading segments. It is of a rich carmine colour externally, becoming paler at the base, and orange-yellow within. The edges of the segments are slightly tinged with green. The stamens, though apparently very short, and inserted into the upper part of the tube between the segments, may be traced down its internal surface to the base. The anthers are oblong, heart-shaped; the germ superior, ovate; the style about the length of the corolla, and terminating in a linear fringed stigma projecting considerably beyond it. The capsule is double, consisting of two cohering, globular, one-celled portions, and containing many seeds.

The plant is a native of our Southern States, being seldom if ever found North of the Potomac. It grows in rich soils on the borders of woods, and flowers from May to July. The root is the part recognised as officinal in the United States Pharmacopœia, although the whole plant is gathered and dried for sale. It is collected by the Creek and Cherokee Indians, who dispose of it to the white traders. By these it is packed in casks, or more commonly in large bales, weighing from three hundred to three hundred and fifty pounds. That contained in casks is to be preferred, as less liable to be damp and mouldy. Owing to the imperfect manner in which the plant is dried, it seldom happens that packages of it reach the market free from dirt and mouldiness, and having the stalks of a bright colour. Parcels have sometimes been brought free from the stalks, and have commanded more than double the price of the drug prepared in the usual way.

Properties. Pink-root consists of numerous slender, branching, crooked, wrinkled fibres, from three to six inches long, attached to a knotty head or caudex, which exhibits traces of the stems of former years. It is of a brownish or yellowish-brown colour externally, of a faint smell, and a sweetish, slightly bitter, not very disagreeable taste. Its virtues are extracted by boiling water. The root, analyzed by M. Feneulle, yielded a fixed and volatile oil, a small quantity of resin, a bitter substance supposed to be the active principle, a mucilaginous saccharine matter, albumen, gallic acid, the malates of potassa and lime, &c., and woody fibre. The principle upon which the virtues of the root are thought to depend, is brown, of a bitter nauseous taste like that of the purgative matter of the leguminous plants, and when taken internally produces vertigo and a kind of intoxication.

The stalks, which, with the leaves, are usually attached to the root, are oval below the first pair of leaves, and then become obscurely four-sided. The leaves, when good, have a fresh greenish colour, and an odour somewhat like that of tea. In taste they resemble the root, and afforded to M. Feneulle nearly the same principles. The quantity, however, of the bitter substance was less, corresponding with their inferior efficacy. This circumstance should cause their rejection from the shops, as the inequality in power of the two portions of the plant would lead to uncertainty in the result, when they are both employed. The root alone is wisely directed by the Pharmacopœias.

The roots are sometimes mixed with those of other plants, particularly of a small vine which twines round the stem of the Spigelia. These are long, slender, crooked, yellowish, thickly set with short capillary fibres, and much smaller and lighter coloured that the pink-root. They should be separated before the latter is used. The activity of spigelia is somewhat diminished by time.

Medical Properties and Uses. Pink-root is generally considered among the most powerful anthelmintics. In the ordinary dose it usually produces little sensible effect on the system; more largely given it acts as a cathartic, though unequal and uncertain in its operation; in overdoses it excites the circulation, and determines to the brain, giving rise to vertigo, dimness of vision, dilated pupils, spasm of the facial muscles, and sometimes even to general convulsions. Spasmodic movements of the eyelids have been observed among the most common attendants of its narcotic action. The death of two children who expired in convulsions was attributed by Dr. Chalmers to the influence of spigelia. The narcotic effects are said to be less apt to occur when the medicine purges, and to be altogether obviated by combining it with cathartics. The danger from its employment cannot be great, as it is in very general use in the United States, both in regular and domestic practice, and we never hear at present of serious consequences. Its effects upon the nervous system have been erroneously conjectured to depend on other roots sometimes mixed with the genuine. The vermifuge properties of spigelia were first learned from the Cherokee Indians. They were made known to the medical profession by Drs. Lining, Garden, and Chalmers of South Carolina. The remedy stands at present in this country at the head of the anthelmintics. It has also been recommended in infantile remittents and other febrile diseases; but is entitled to little confidence in these complaints.

It may be given in substance or infusion. The dose of the powdered root for a child three or four years old, is from ten to twenty grains, for an adult from one to two drachms, to be repeated morning and evening for several days successively, and then followed by a brisk cathartic. The practice of preceding its use by an emetic has been generally abandoned. It is frequently given in combination with calomel. The infusion, however, is the most common form of administration. (See *Infusum Spigeliæ.*) It is usually combined with senna or some other cathartic, to ensure its action on the bowels. A preparation generally kept in the shops and much prescribed by physicians, under the name of *worm tea*, consists of pink-root, senna, manna, and savine, mixed together, in various proportions, to suit the views of different individuals.

SPIRÆA. *U.S. Secondary.*

Hardhack.

"Spiræa tomentosa. Radix. *The root.*" *U.S.*

SPIRÆA. *Sex. Syst.* Icosandria Pentagynia.—*Nat. Ord.* Rosaceæ.

Gen. Ch. *Calyx* spreading, five-cleft, inferior. *Petals* five, equal, roundish. *Stamens* numerous, exserted. *Capsules* three to twelve, internally bivalve, each one to three-seeded. *Nuttall.*

Spiræa tomentosa. Willd. *Sp. Plant.* ii. 1056; Rafinesque, *Med. Flor.* vol. ii. This is an indigenous shrub, two or three feet high, with numerous simple, erect, round, downy, and purplish stems, furnished with alternate leaves closely set upon very short footstalks. The leaves are ovate lanceolate, unequally serrate, somewhat pointed at both ends, dark green on their upper surface, whitish and tomentose beneath. The flowers are of a beautiful red or purple colour, and disposed in terminal, compound, crowded spikes or racemes.

The hardhack flourishes in low grounds, from New England to Carolina, but is most abundant in the Northern States. It flowers in July and August. All parts of it are medicinal. The root, though designated in the Pharmacopœia, is, according to Dr. A. W. Ives, the least valuable portion. The taste of the plant is bitter and powerfully astringent. Among its constituents are tannin, gallic acid, and bitter extractive. Water extracts its sensible properties and medicinal virtues.

Medical Properties and Uses. Spiræa is tonic and astringent, and may be used in diarrhœa, cholera infantum, and other complaints in which astringents are indicated. In consequence of its tonic powers it is peculiarly adapted to cases of debility; and, from the same cause, should not be given during the existence of inflammatory action, or febrile excitement. It is said to have been employed by the aborigines of our country; but was first brought before the notice of the medical profession by Dr. Cogswell of Hartford, in Connecticut. It is said to be less apt to disagree with the stomach than most other astringents.

The form in which it is best administered is that of an extract, prepared by evaporating the decoction of the leaves, stems, or root. The dose is from five to fifteen grains, repeated several times a day. A decoction prepared by boiling an ounce of the plant in a pint of water, may be given in the dose of one or two fluidounces. W.

SPONGIA. *U.S., Lond.*

Sponge.

"Spongia officinalis." *U.S.*

Off. Syn. SPONGIA OFFICINALIS. *Ed., Dub.*

Eponge, *Fr.;* Badeschwamm, *Germ.;* Spugna, *Ital.;* Esponja, *Span., Portug.;* Isfung, *Arab.*

The sponge is now universally admitted to be an animal belonging to the class of Zoophites. It is characterized as "a flexile, fixed, torpid, polymorphous animal, composed either of reticulate fibres, or masses of small spires interwoven together, and clothed with a gelatinous flesh full of small mouths on its surface, by which it absorbs and ejects water." More than two hundred and fifty species have been described by naturalists, of which several are probably employed, though the *Spongia officinalis* is the only one designated in the Pharmacopœias. They inhabit the bottom of the sea, where they are fixed to rocks or other solid bodies; and are most abundant within the tropics. They are collected chiefly in the Mediterranean and Red Seas, and in those of the East and West Indies. In the Grecian Archipelago many persons derive their support altogether from diving for sponges. When first collected they are enveloped in a gelatinous coating, which forms part of the animal, and is separated by washing with water. Large quantities of the coarser kinds are imported from the Bahamas; but the finest and most esteemed are brought from the Mediterranean.

Sponge, as found in commerce, is in yellowish-brown masses of various shape and size, light, porous, elastic, and composed of fine, flexible, tenacious fibres, interwoven in the form of cells and meshes. It usually contains numerous minute fragments of coral or stone, or small shells, from which it must be freed before it can be used for ordinary purposes. Sponge is prepared by macerating it for several days in cold water, beating it in order to break up the concretions which it contains, and dissolving what cannot thus be separated of the calcareous matter by muriatic acid diluted with thirty parts of water. By this process, it is rendered perfectly soft, and fit for surgical use. It may be bleached by steeping it in water impregnated with sulphurous acid, or by exposure in a moist state to the action of chlorine. When intended for surgical purposes, the softest, finest, and most elastic sponges should be selected; for forming *burnt sponge*, the coarser will answer equally well.

According to Mr. Hatchett, the chemical constituents of sponge are gelatin, albumen, common salt, and carbonate of lime. The presence of magnesia, silica, iron, and phosphorus has also been detected; and iodine, in the state of hydriodate of soda, is among the ingredients.

Medical Properties and Uses. Sponge, in its unaltered state, is not employed as a medicine; but in consequence of its softness, porosity, and property of imbibing liquids, it is very useful in surgical operations. From the same qualities it may be advantageously applied over certain ulcers, the irritating sanies from which it removes by absorption. Compressed upon a bleeding vessel, it is sometimes useful for promoting the coagulation of the blood, especially in hemorrhage from the nostrils. In the shape of sponge tent it is also useful for dilating sinuses. This is prepared by dipping sponge into melted wax, compressing it between two flat surfaces till the wax hardens, and then cutting it into pieces of a proper form and size. By the heat of the body the wax becomes soft, and the sponge expanding by the imbibition of moisture, gradually dilates the wound or ulcer in which it may be placed. Reduced to the state of charcoal by heat, sponge has long been used as a remedy in goitre. (See *Spongia Usta.*) Its efficacy in this complaint, which was formerly considered very doubtful by many physicians, has been generally admitted since the discovery of iodine.

STANNUM. *U.S., Lond., Dub.*

Tin.

Off. Syn. STANNI LIMATURA. *Ed.*

Etain, *Fr.;* Zinn, *Germ.;* Stagno, *Ital.;* Estanno, *Span.*

Tin is one of those metals which have been known from the earliest ages. It exists in the earth generally as an oxide, rarely as a sulphuret, and is by no means generally diffused. It is found in England, Spain, Germany, Bohemia, and Hungary, in Europe; in the island of Banca and the peninsula of Malacca in Asia; and in Chili and Mexico in America. It has not been discovered in the United States. The English mines are the most productive, but those of Asia furnish the purest tin. The metal is extracted exclusively from the native oxide. When this occurs in its purest state, under the form of detached roundish grains, called *stream tin*, the reduction is effected simply by heating with charcoal. When the oxide is extracted from mines, it requires to be freed, by pounding and washing, from the adhering gangue; after which it is roasted to drive off sulphur, arsenic, and antimony, and finally reduced in furnaces by means of stone coal. The metal, as thus obtained, is not pure, and requires to be subjected to a gentle heat, whereby the pure tin enters first into fusion, and is thus separated from the impurities, which consist of tin united with copper, arsenic, iron, and antimony. The pure metal, thus obtained, is the *grain-tin* of the English; while the impure residue, after being fused, constitutes *ordinary* or *block-tin.*

Properties. Tin is a malleable, rather soft metal, of a silver-white colour, and possessing considerable brilliancy. It undergoes but a slight tarnish in the air. Its taste is slight, and when rubbed it exhales a peculiar smell. Its ductility and tenacity are small, and when bent to and fro, it emits a crackling noise, which is characteristic of this metal. Its sp. gr. is 7.29, melting point 442°, and equiv. number 57.9. It forms three oxides, a protoxide, sesquioxide, and deutoxide. The *protoxide* is of a grayish-black colour, and consists of one equiv. of tin 57.9 and one of oxygen 8=65.9. The *sesquioxide* is gray, and is composed of two equiv. of tin 115.8, and three of oxygen 24=139.8. The *deutoxide* is of a white colour, and constitutes the native oxide. It consists of one equiv. of tin 57.9 and two of oxygen 16=73.9

The tin of commerce is often impure, being contaminated with other metals, either by fraud, or in consequence of the mode of extraction from the ore. When its colour has a bluish or grayish cast, the presence of copper, lead, iron, or antimony, may be suspected. Arsenic renders it whiter, but at the same time harder than natural; and lead, copper, and iron, cause it to become brittle. Pure tin, dissolved in nitro-muriatic acid, gives a white precipitate with ferrocyanate of potassa. A blue precipitate with this test indicates iron; a purple one, copper; and a violet-blue one, both iron and copper. If lead be present, a precipitate will be produced by sulphate of soda. The Malacca and Banca tin, and the English grain-tin, are the purest kinds found in commerce. Block tin and the metal obtained from Germany are always of inferior quality.

Uses. Tin enters into the composition of bronze, bell-metal, pewter, and plumbers' solder. It is used also in making tin-plate, in silvering looking-glasses, and in forming the muriate of tin, a combination essential to the perfection of the scarlet dye. It is employed in fabricating various vessels and instruments, useful in domestic economy and the arts. Being unaffected by weak acids, it forms a good material for vessels intended for boiling operations in pharmacy. For its medical properties, see *Pulvis Stanni.*

Off. Prep. Pulvis Stanni, *U.S.*, *Ed.*, *Dub.* B.

STAPHISAGRIÆ SEMINA. *Lond.*

Stavesacre seeds.

"Delphinium Staphisagria. *Semina.*" *Lond.*

Off. Syn. DELPHINII STAPHISAGRIÆ SEMINA. *Ed.;* DELPHINIUM STAPHISAGRIA. Semina. *Dub.*

Staphisaigre, *Fr.;* Stephanskraut, Läusekraut, *Germ.;* Stafisagria, *Ital.;* Abarraz, *Span.*

Delphinium. See DELPHINIUM.

Delphinium Staphisagria. Willd. *Sp. Plant.* ii. 1231.; Woodv. *Med. Bot.* p. 471. t. 168. Stavesacre is a handsome annual or biennial plant, one or two feet high, with a simple, erect, downy stem, and palmate, five or seven-lobed leaves supported on hairy footstalks. The flowers are bluish or purple, in terminal racemes, with pedicels twice as long as the flower, and bracteoles inserted at the base of the pedicel. The nectary is four-leaved and shorter than the petals, which are five in number, the uppermost projected backward so as to form a spur which encloses two spurs of the upper leaflets of the nectary. The seeds are contained in straight, oblong capsules. The plant is a native of the South of Europe.

Properties. Stavesacre seeds are large, irregularly triangular, wrinkled, externally brown, internally whitish and oily. They have a slight but disagreeable odour, and an extremely acrid, bitter, hot, nauseous taste. Their virtues are extracted by water and alcohol. Analyzed by MM. Lassaigne and Feneulle, they yielded a brown and a yellow bitter principle, a volatile oil, a fixed oil, albumen, an azotized substance, a mucilaginous saccharine matter, mineral salts, and a peculiar vegetable alkali called *delphine* or *delphia*, which exists in the seeds combined with an excess of malic acid. It is white, pulverulent, inodorous, of a bitter acrid taste, fusible by heat and becoming hard and brittle upon cooling, slightly soluble in cold water, very soluble in alcohol and ether, and capable of forming salts with the acids. It is obtained by boiling a decoction of the seeds with magnesia, collecting the precipitate, and treating it with alcohol, which dissolves the *delphia* and yields it upon evaporation. According to M. Couerbe, this substance consists of three distinct principles,—one of a resinous nature separated from its solution in diluted sulphuric acid by the addition of nitric acid, another distinguished by its insolubility in ether, and named by M. Couerbe, *staphisain*, and the third soluble both in alcohol and ether, and deserving to be considered as pure *delphia.* (*Journ. de Pharm.* xix. 519.)

Medical Properties and Uses. The seeds were formerly used as an emetic and cathartic, but have been abandoned in consequence of the violence of their action. Powdered and mixed with lard they are employed in some cutaneous diseases, and to destroy lice in the hair. An infusion in

vinegar has been applied to the same purpose. In some countries the seeds are used to intoxicate fish in the same manner as the Cocculus Indicus. Delphia is highly poisonous in small doses, exerting its effects chiefly on the nervous system.

STATICE. *U.S. Secondary.*

Marsh Rosemary.

"Statice Caroliniana. Radix. *The root.*" *U. S.*

STATICE. *Sex. Syst.* Pentandria Pentagynia.—*Nat. Ord.* Plumbagineæ.

Gen. Ch. *Calyx* one-leaved, entire, plaited, scariose. *Petals* five. *Seed* one, superior. *Nuttall.*

Statice Caroliniana. Walter, *Flor. Car.* 118; Bigelow, *Am. Med. Bot.* ii. 51. This is considered by Nuttall, Torrey, and some other botanists, as a mere variety of the *Statice Limonium* of Europe. Pursh, Bigelow, and others follow Walter in considering it as a distinct species. It is an indigenous maritime plant, with a perennial root, sending up annually tufts of leaves, which are obovate or cuneiform, entire, obtuse, mucronate, smooth, and supported on long footstalks. They differ from the leaves of the *S. Limonium* in being perfectly flat on the margin, while the latter are undulated. The flower-stem is round, smooth, from a few inches to a foot or more in height, sending off near its summit numerous alternate subdividing branches, which terminate in spikes, and form altogether a loose panicle. The flowers are small, bluish-purple, erect, upon one side only of the common peduncle, with a mucronate scaly bracte at the base of each, a five-angled, five-toothed calyx, and spatulate, obtuse petals.

The marsh rosemary grows in the salt marshes along the seacoast, from New England to Florida, and flowers in August and September. The root, which is the officinal portion, is large, spindle-shaped or branched, fleshy, compact, rough, and of a purplish-brown colour. To the taste it is bitter and extremely astringent, but is without odour. It contains abundance of tannin and gallic acid, with extractive matter and some common salt. Water extracts its virtues.

Medical Properties and Uses. Statice is powerfully astringent, and in some parts of the United States, particularly in New England, is much employed. It may be used for all the purposes for which kino and catechu are given; but its chief popular application is to aphthous and ulcerative affections of the mouth and fauces. Dr. Baylies of Massachusetts found it highly useful in cynanche maligna, both as an internal and local remedy. It is employed in the form of infusion or decoction.

STILLINGIA. *U. S. Secondary.*

Queen's-root.

"Stillingia sylvatica. Radix. *The root.*" *U. S.*

STILLINGIA. *Sex. Syst.* Monœcia Monadelphia.—*Nat. Ord.* Euphorbiaceæ.

Gen. Ch. MALE. *Involucre* hemispherical, many-flowered, or wanting. *Calyx* tubular, eroded. *Stamens* two and three, exserted. FEMALE. *Calyx* one-flowered, inferior. *Style* trifid. *Capsule* three-grained. *Nuttall.*

Stillingia sylvatica. Willd. *Sp. Plant.* iv. 588. This is an indigenous, perennial plant, with herbaceous stems, and alternate, sessile, oblong or lanceolate oblong, obtuse, serrulate leaves, tapering at the base, and accompanied with stipules. The male and female flowers are distinct upon the same plant. They are yellow, and arranged in the form of a spike, of which the upper part is occupied by the male, the lower by the female flowers. The male florets are scarcely longer than the bracteal scales.

The plant grows in pine barrens, from Virginia to Florida, flowering in May and June. When wounded, it emits a milky juice. The root, which is the part used, is large, thick, and woody. We are not acquainted with its precise properties; but understand that it is much employed in the Southern States. It is said to be purgative and alterative; and probably possesses more or less of the acrid quality common to the Euphorbiaceæ. It is used in lues venerea, obstinate cutaneous affections, and other complaints which are usually treated with sarsaparilla. W.

◆

STRAMONII FOLIA. *U.S.*

Thorn-apple Leaves.

STRAMONII SEMEN. *U.S.*

Thorn-apple Seed.

"Datura stramonium. Folia. Semina. *The leaves and seeds.*" *U.S.*

Stramoine, Pomme épineuse, *Fr.;* Stechapfel, *Germ.;* Stramonio, *Ital.;* Estramonio, *Span.*

Datura. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Solaneæ.

Gen. Ch. Corolla funnel-shaped, plaited. *Calyx* tubular, angular, deciduous. *Capsule* four-valved. *Willd.*

Datura Stramonium. Willd. *Sp. Plant.* i. 1008; Bigelow, *Am. Med. Bot.* i. 17; Woodv. *Med. Bot.* p. 197. t. 74. The thorn-apple is an annual plant, of rank and vigorous growth, usually about three feet high, but in a very rich soil sometimes rising six feet or more. The root is large, whitish, and furnished with numerous fibres. The stem is erect, round, smooth, somewhat shining, simple below, dichotomous above, with numerous spreading branches. The leaves, which stand on short round footstalks in the forks of the stem, are five or six inches long, of an ovate triangular form, irregularly sinuated and toothed at the edges, unequal at the base, of a dark-green colour on the upper surface, and pale beneath. The flowers are large, axillary, solitary, and peduncled: having a tubular, pentangular, five-toothed calyx, and a funnel-shaped corolla with a long tube, and a waved plaited border, terminating in five acuminate teeth. The upper portion of the calyx falls with the deciduous parts of the flower, leaving its base, which becomes reflexed, and remains attached to the fruit. This is a large, fleshy, roundish ovate, four-valved, four-celled capsule, thickly covered with sharp spines, and containing numerous seeds attached to a longitudinal receptacle in the centre of each cell. It opens at the summit.

Dr. Bigelow describes two varieties of this species of Stramonium, one with green stems and white flowers; the other with a dark reddish stem, minutely dotted with green, and purplish flowers striped with deep purple on the inside. The latter variety, however, is considered by most botanists as a distinct species, being the *D. Tatula* of Linn. The properties of both are the same.

It is doubtful to what country this plant originally belonged. Many European botanists refer it to North America, while we in return trace it to the old continent. Nuttall considers it as having originated in South America or in Asia; and it is probable that its native country is to be found in some portion of the East. Its seeds being retentive of life and easily germinating, are taken in the earth put on shipboard for ballast from one country to another, not unfrequently springing up upon the passage, and thus propagating the plant in all regions which have any commercial connexion. In the United States it is found everywhere in the vicinity of cultivation, frequenting dung-heaps, the road-sides and commons, and other places where a rank soil is created by the deposited refuse of towns and villages. Its flowers appear from May to July or August, according to the latitude. Where the plant grows abundantly, its vicinity may be detected by the rank odour which it diffuses to some distance around. All parts of it possess medicinal properties. The herbaceous portion is directed by the Edinburgh College; the herb and seeds by that of Dublin; and the leaves and seeds by the Pharmacopœias of the United States and of London. The leaves may be gathered at any time from the appearance of the flowers till the autumnal frost. In the common language of this country, the plant is most known by the name of *Jamestown weed*, derived probably from its having been first observed in the neighbourhood of that old settlement in Virginia.

1. The *fresh leaves* when bruised emit a fetid narcotic odour, which they ose upon drying. Their taste is bitter and nauseous. These properties, ogether with their medical virtues, are imparted to water and alcohol. Water distilled from them, though possessed of their odour in a slight degree, is destitute of their active properties. They contain, according to Promnitz, 0.58 per cent. of gum, 0.6 of extractive, 0.64 of green starch, 0.15 of albumen, 0.12 of resin, 0.23 of saline matters, 5.15 of lignin, and 91.25 of water.

2. The *seeds* are small, kidney-shaped, flattened on the sides, of a dark rown almost black colour, inodorous, and of the bitter nauseous taste of the eaves, with some degree of acrimony. They were minutely analyzed by Brandes, who found, besides a peculiar alkaline principle called *daturia*, a lutinous matter, albumen, gum, a butyraceous substance, green wax, resin nsoluble in ether, fixed oil, bassorin, sugar, gummy extractive, orange-oloured extractive, and various saline and earthy substances. *Daturia* exists n the seeds combined with an excess of malic acid. In its pure state it is rystallizable in the form of acicular prisms, nearly insoluble in water and old alcohol, soluble in boiling alcohol, and capable of neutralizing the acids. s salts are very soluble; and the sulphate, muriate, and nitrate are crystalzable. It is said to produce upon the system narcotic effects similar to those stramonium, but has hitherto been little used. To obtain it, the seeds are iled in alcohol, the alcoholic solution treated with magnesia, and the prepitate submitted to the action of boiling alcohol, which yields the daturia on cooling, and still further by evaporation. Mr. Simes of Philadelphia peated the process of Brandes, adding the magnesia while the liquor was ll hot, and treating the last alcoholic solution with animal charcoal before bmitting it to evaporation. He obtained crystals of a substance which he und to be slightly bitter and acrid, and to possess the other properties menned as belonging to daturia. He experienced headach to a violent degree

after tasting its salts; and killed a small cat with four grains of the muriate. Mr. Simes treated the green and dried leaves in the same manner as the seeds. From the former he obtained no crystals, from the latter a crystalline deposite, but so small in quantity that he could not determine its properties. (*Journ. of the Phil. Col. of Pharm.* v. 114.) Berzelius states that this salifiable base has been ascertained by other chemists, and even by Brandes himself, to be nothing more than the phosphate of magnesia. (*Traité de Chimie*, vi. 319.)

Medical Properties and Uses. Stramonium is a powerful narcotic. When taken in quantities sufficient to affect the system moderately, it usually produces more or less cerebral disturbance, indicated by vertigo, headach, dimness or perversion of vision, and confusion of thought, sometimes amounting to slight delirium or a species of intoxication. At the same time peculiar deranged sensations are experienced about the fauces, œsophagus, and trachea, increased occasionally to a feeling of suffocation, and often attended with nausea. A disposition to sleep is sometimes, but not uniformly produced. The pulse is not materially affected. The bowels are rather relaxed than confined, and the secretions from the skin and kidneys not unfrequently augmented. These effects pass off in five or six hours, or in a shorter period, and no inconvenience is subsequently experienced. (*Marcet, Gredding*, &c.) Taken in poisonous doses, the narcotic produces cardialgia, excessive thirst, nausea and vomiting, a sense of strangulation, anxiety and faintness, partial or complete blindness with dilatation of the pupil, vertigo, delirium sometimes of a furious sometimes of a whimsical character, tremors of the limbs, palsy, and ultimately stupor and convulsions. From all these symptoms the patient may recover; but in numerous instances they have terminated in death. To evacuate the stomach by emetics or the stomach pump is the most effectual means of affording relief.

Though long known as a poisonous and intoxicating herb, stramonium was first introduced into regular practice by Baron Störck of Vienna, who found some advantage from its use in mania and epilepsy. Subsequent observation has confirmed his estimate of the remedy; and numerous cases are on record in which benefit has accrued from it in these complaints. It can be of use, however, only in those cases which depend solely on irregular nervous action. Other diseases in which it has been found beneficial are neuralgic and rheumatic affections, syphilitic pains, cancerous sores, and spasmodic asthma. In the last complaint it has acquired considerable reputation. It is employed only during the paroxysm, which it very often greatly alleviates or altogether subverts. The practice was introduced into Great Britain from the East Indies, where the natives are in the habit of smoking the dried root and lower part of the stem of the *Datura ferox*, in the paroxysms of this distressing complaint. The same parts of the *D. Stramonium* were substituted and found equally effectual. To prepare the roots for use, they are quickly dried, cut into pieces, and beat so as to loosen the texture. The dried leaves answer the same purpose. They are smoked by means of common tobacco-pipe. The smoke produces a sense of heat in the lungs followed by copious expectoration, and attended frequently with temporary vertigo or drowsiness, and sometimes with nausea. The remedy shoul never be used in plethoric cases, unless preceded by ample depletion. Dangerous and even fatal consequences are said to have resulted from its incautious or improper use. Stramonium has sometimes been given by the stomach in the same complaint.

Externally the medicine is used advantageously as an ointment or cataplasm in irritable ulcers, inflamed tumours, swelling of the mammæ, an painful hemorrhoidal affections. By American surgeons it is very frequently applied to the eye, in order to produce dilatation of the pupil, previously to the operation for cataract; and is found equally efficacious with belladonna. For this purpose the extract, mixed with lard, is generally rubbed over the eyelid, or a solution of it dropped into the eye.

Of the parts of the plant employed, the seeds are the most powerful. They may be given in the dose of a grain twice a day; and an extract made by evaporating the decoction, in one quarter or half of the quantity. The dose of the powdered leaves is two or three grains. The inspissated juice of the fresh leaves, which is the officinal extract, is more commonly prescribed than any other preparation, and may be administered in the quantity of one grain. (See *Extractum Stramonii.*) There is also an officinal tincture to which the reader is referred. Whatever preparation is used, the dose should be gradually increased till the narcotic operation becomes evident, or relief from the symptoms of the disease is obtained. The quantity of fifteen or twenty grains of the powdered leaves, and a proportionate amount of the other preparations, have often been given daily without unpleasant effects.

Storax, *Fr., Germ.;* Storace, *Ital.;* Estoraque, *Span.*

Styrax. See BENZOINUM.

Styrax officinale. Willd. *Sp. Plant.* ii. 623; Woodv. *Med. Bot.* p. 291. t. 101. This species of Styrax is a tree which rises from fifteen to twenty-five feet in height, sends off many branches, and is covered with a rough gray bark. The leaves are alternate, petiolate, entire, oval, pointed, of a bright-green on their upper surface, white with a cotton-like down upon the under, about two inches in length, and an inch and a half in breadth. The flowers are united in clusters of three or four at the extremities of the branches. They are white, and bear considerable resemblance to those of the orange.

This tree is a native of Syria and other parts of the Levant, and has become naturalized in Italy, Spain, and the South of France, where, however, it does not yield balsam. This circumstance has induced some naturalists to doubt whether the *Styrax officinale* is the real source of storax; and as the *Liquidambar styraciflua* of this country affords a balsam closely analogous to that under consideration, Bernard de Jussieu conjectured that the latter might be derived from another species of the same genus, the *L. orientale* of Lamarck, which is more abundant in Syria than *Styrax*.

Storax is obtained in Asiatic Turkey by making incisions into the trunk of the tree. Several kinds are mentioned in the books. The purest is the *storax in grains*, which is in whitish, yellowish-white, or reddish-yellow tears, about the size of a pea, opaque, soft, adhesive, and capable of uniting so as to form a mass. Another variety formerly called *storax calamita*, from the circumstance, as is supposed, that it was brought wrapped in the leaves of a kind of reed, consists of dry and brittle masses, formed of yellowish agglutinated tears, in the interstices of which is a brown or reddish matter. The French writers call it *storax amygdaloïde.* Both this and the preceding variety have a very pleasant odour like that of vanilla. Neither of them, however, is brought to our markets.

A third variety, which is sometimes sold as the *storax calamita,* is in brown or reddish-brown masses of various shapes, light, friable, yet possessing a certain degree of tenacity, and softening under the teeth. It evidently consists of saw-dust, united either with a portion of the balsam, or with other analogous substances. As found in the shops of this country, it is usually in the state of a coarse, soft, dark-coloured powder, mingled with occasional light friable lumps of various magnitude, and containing very little of the balsam. When good, it should yield upon pressure between two hot plates, a brown, resinous fluid, having the odour of storax.

Another variety found in our market, is a semi-fluid adhesive matter, called *liquid storax,* which is brown or almost black upon the surface exposed to the air, but of a light slightly greenish gray colour within, and of an odour somewhat like that of the Peruvian balsam. It is kept in jars, and is the kind most employed. What is the source of liquid storax is not certainly known. Some suppose it to be derived by decoction from the young branches of the *Liquidambar styraciflua;* but some of the genuine juice of this plant, brought from New Orleans, which we have had an opportunity of inspecting, has an odour entirely distinct from that of the substance under consideration.

General Properties. Storax has a fragrant odour and aromatic taste. It melts with a moderate heat, and when the temperature is raised takes fire and burns with a white flame, leaving a light spongy carbonaceous residue. It imparts its odour to water, which it renders yellow and milky. With the exception of impurities, it is wholly dissolved by alcohol and ether. Newmann obtained from 480 grains of storax 120 of watery extract; and from an equal quantity 360 grains of alcoholic extract. It yields benzoic acid by distillation, and is therefore entitled to the rank of a balsam. It contains also resin and volatile oil.

Medical Properties and Uses. This balsam is a stimulant expectorant, and was formerly recommended in phthisis, chronic catarrh, asthma, and amenorrhœa; but it is very seldom used at present, except as a constituent of the compound tincture of benzoin. The liquid storax has recently been recommended in gonorrhœa and leucorrhœa as equally effectual with copaiba, and less disagreeable. From ten to twenty grains may be given twice a day, and the dose gradually increased.

SUCCINUM. *U.S., Lond., Ed., Dub.*

Amber.

Succin, Ambre jaune, Karabé, *Fr.;* Bernstein, *Germ.;* Ambra, *Ital.;* Succino, *Span.*

Amber is a kind of fossil resin of vegetable origin, occurring generally in small detached masses, in alluvial deposites, in different parts of the world. It is found chiefly in Prussia, either on the seashore, where it is thrown up by the Baltic, or underneath the surface, in the alluvial formations along the coast. It occurs, also, in considerable quantities near Catania, in Sicily. It is most frequently associated with bituminous wood and lignite, and sometimes encloses twigs of vegetables, and insects. In the United States, it was found in Maryland, at Cape Sable, near Magothy river, by Dr. Troost. In this locality it is associated with iron pyrites and lignite. It has also been discovered in New Jersey. The amber consumed in this country, however, is brought from the ports of the Baltic.

Properties. Amber is a brittle solid, generally in small irregular masses, permanent in the air, having a homogeneous texture and vitreous fracture, and susceptible of a fine polish. Its colour is generally yellow, either light or deep; but occasionally it is reddish-brown, or even deep brown. It has no taste, and is inodorous unless when heated, when it exhales a peculiar, aromatic, not unpleasant smell. It is usually translucent, though occasionally transparent or opaque. Its sp. gr. is 1.078. Water and alcohol scarcely act on it. When heated in the open air, it softens, melts, swells, and at last inflames, leaving, after combustion, a small portion of ashes. Subjected to distillation in a retort furnished with a tubulated receiver, it yields, first, a sour yellow liquid; and afterwards a thin yellowish oil, with a yellow crystalline sublimate, which is deposited in the neck of the retort and the upper part of the receiver. In the mean time a considerable quantity of combustible gas is given off, which must be allowed to escape from the tubulure of the receiver. By continuing the heat the oil gradually deepens in colour, until, towards the end of the distillation, it becomes black and of the consistence of pitch. The oil obtained is called *oil of amber;* the crystalline sublimate is of an acid nature, and is denominated *succinic acid.* As thus obtained it is impure, being contaminated with the oil.

Resinous substances, particularly copal, are sometimes fraudulently mixed with amber. They may be detected by the difference in their colour and fracture, and by their not emitting the peculiar odour of amber when thrown upon hot iron.

Composition. According to Berzelius, amber consists of 1. a volatile oil of an agreeable odour in small quantity, 2. a yellow resin, intimately united with a volatile oil, very soluble in alcohol, ether, and the alkalies, easily fusible, and resembling ordinary resins; 3. another resin, also combined with volatile oil, soluble in ether and the alkalies, sparingly soluble in cold, but more soluble in boiling alcohol; 4. succinic acid; 5. a principle, insoluble in alcohol, ether, and the alkalies, having some analogy to the lac resin of John. It also contains a strongly odorous, bright yellow balsam, which hardens by time, but preserves in part its odour. The ultimate constituents of amber are hydrogen, carbon, and oxygen.

Pharmaceutical Uses, &c. Amber was held in high estimation by the ancients as a medicine; but at present it is only employed in pharmacy and the arts. In pharmacy it is used to prepare succinic acid and oil of amber. (See *Acidum Succinicum* and *Oleum Succini.*) In the arts, it is made into ornaments, and employed in preparing varnishes. When put to the latter use it requires to be first subjected to roasting, whereby it is rendered soluble in alcohol and the fat oils.

SULPHUR. *U.S.*

Sulphur.

"Sulphur sublimatum et lotum. *Sulphur sublimed and washed.*" *U.S.*

Off. Syn. SULPHUR. SULPHUR SUBLIMATUM. SULPHUR LOTUM. *Lond.;* SULPHUR SUBLIMATUM. SULPHUR SUBLIMATUM LOTUM. *Ed.;* SULPHUR SULIMATUM. SULPHUR LOTUM. *Dub.*

Brimstone; Soufre, *Fr.;* Schwefel, *Germ.;* Zolfo, *Ital.;* Azufre, *Span.*

The officinal names placed at the head of this article designate the several forms in which uncombined sulphur is used in pharmacy and medicine. The London College alone admits the common roll brimstone, which it designates by the officinal name of *sulphur*, while the three British Colleges agree in recognising both *sublimed sulphur* and *washed sulphur*. The latter only is admitted in the United States Pharmacopœia, being designated by the appellation, *sulphur*, a name injudiciously applied in this sense, as it had previously been used in another acceptation by the London College. After these explanations, it is perceived that the names adopted by the British Colleges, are not strictly synonymes of "Sulphur" in the sense of the United States Pharmacopœia; but the preparations designated by them are so analogous, as to render it expedient to notice them under the same head. We shall accordingly treat of sulphur first in a general way, and afterwards, under the several forms of *roll*, *sublimed*, and *washed sulphur*.

Natural States. Sulphur is very generally disseminated throughout the mineral kingdom, and is almost always present, in minute quantity, in animal and vegetable matter. Among vegetables, it is particularly abundant in the cruciform plants. It occurs in the earth, either native or in combination. When native it is found in masses, translucent or opaque, or in the powdery form, mixed with various earthy impurities. In combination, it is usually united with certain metals, such as iron, lead, mercury, antimony, copper, and zinc, forming compounds called sulphurets. Native sulphur is most abundant in volcanic countries. The most celebrated mines of it are found at Solfaterra in the kingdom of Naples, in Sicily, and in the Roman States. It occurs also, in small quantities, in different localities in the United States.

Extraction, &c. Sulphur is obtained either from sulphur earths, or from the native sulphurets of iron and copper, called iron and copper pyrites. The sulphur earths are placed in earthen pots, set in oblong furnaces of brick-work, and surmounted by a horizontal tube, which communicates with another pot with a hole in its bottom, underneath which a vessel is placed containing water. Fire being applied, the sulphur rises in vapour, leaving the impurities behind, and being condensed again, drops from the perforated pot into the water beneath. Sulphur, as thus obtained, is called *crude sulphur*, and contains about one-twelfth of its weight of earthy matter. For purification, it is generally melted in a cast iron vessel. When the fusion is complete, the impurities subside, and the purer sulphur is dipped out and poured into cylindrical wooden moulds, which give it the form of solid cylinders, called in commerce *roll sulphur*, or *cane brimstone*. The dregs of this process constitute a very impure kind of sulphur, known by the name of *sulphur vivum* in the shops.

The above process purifies the sulphur but imperfectly, and at the same time causes a considerable loss; as the dregs, just alluded to, contain a large proportion of sulphur. A more eligible mode of purification consists in distilling the crude sulphur in a large cast iron vessel, surmounted with a capital, built of masonry and communicating laterally with a chamber of brickwork, furnished with stop-cocks even with its floor, and with a valve in its roof to allow the escape of rarefied air. Besides the opening by which the capital communicates with the chamber, it has another, through which the iron vessel may be charged, and freed from the residue after each distillation. By this apparatus, the sulphur may be obtained either sublimed or in roll. If the distillation be rapidly performed, the chamber will become heated above the melting point of the sulphur, which, consequently, will condense in the liquid state, and may be drawn off by the cocks, and cast into sticks. If, however, the chamber be comparatively large, and the distillation be suspended during the night, its temperature will fall so low that the vapour of the sulphur will be condensed on its surface in the form of an extremely fine powder, known in commerce under the name of *sublimed sulphur*, or *flowers of sulphur.*

The extraction of sulphur from the sulphuret of iron is performed by distilling it in stone-ware cylinders. Half the sulphur contained in the sulphuret is volatilized by the heat, and conducted by means of an adopter into vessels containing water, where it condenses. The residue of the mineral is employed for the purpose of being converted into sulphate of iron, or green vitriol, by exposure to air and moisture. In the Island of Anglesea, large quantities of sulphur are obtained from copper pyrites in the process for extracting that metal. The furnaces in which the ore is roasted are connected by horizontal flues with chambers, in which the volatilized sulphur is condensed. Each chamber is furnished with a door, through which the sulphur is withdrawn once in six weeks.

According to Berzelius, a very economical method of extracting sulphur from iron pyrites is practised in Sweden, which saves the expenditure of fuel. The pyrites is introduced into furnaces with long horizontal chimneys, of which the part next to the furnace is of brick-work, while the rest is formed of wood. The pyrites is kindled below, and continues to burn of itself; and the heat generated causes the stratum immediately above the part kindled to give off half its sulphur, which becomes condensed in flowers in the wooden chimney. As the fire advances, the iron and the other half of the sulphur enter into combustion, and, by the increase of heat thus generated, cause the volatilization of a fresh portion of sulphur. In this manner, the process continues until the whole of the pyrites is consumed. The sulphur thus obtained is pulverulent and very impure, and requires, for purification, to be distilled in iron vessels.

Crude sulphur is employed by the manufacturers of sulphuric acid, and as it is very variable in quality, it becomes important to ascertain its exact value. This may be done by drying a given weight of it, and submitting it to combustion. The weight of the incombustible residue, added to that lost by desiccation, gives the amount of impurity.

Crude sulphur comes to this country principally from Trieste, Messina in Sicily, and the ports of Italy, being imported for the use of the sulphuric acid manufacturers. Roll sulphur and the flowers are usually brought from Marseilles.

Properties. Sulphur is an elementary non-metallic brittle solid, of a pale yellow colour, permanent in the air, and exhibiting a crystalline texture and shining fracture. It has a slight taste, and a perceptible smell when rubbed. When pure, its sp. gr. is about 2; but occasionally, from impurity, it is as high as 2.35. Its equiv. number is 16.1. It is a bad conductor of heat, and becomes negatively electric by friction. It is insoluble in water, but soluble in alkaline solutions, petroleum, fat oils, and, provided it be in a finely divided state, in alcohol and ether. Upon being heated, it begins to volatilize at about 180°, when its peculiar odour is perceived; it melts at 225°, and at 600°, in close vessels, boils, and rises in the form of a yellow vapour, which may be condensed again either in the liquid or pulverulent state, according as the temperature of the recipient is above or below the melting point of the sulphur. If the heating be conducted in open vessels, sulphur takes fire at about the temperature of 300°, and burns with a blue flame, combining with the oxygen of the air, and giving rise to a peculiar gaseous acid called sulphurous acid. As a chemical element, it is exceedingly important, its combinations being numerous, and among the most powerful agents of chemistry. With oxygen, it forms four acids, the *hyposulphurous*, *sulphurous*, *hyposulphuric*, and *sulphuric*, with hydrogen, *hydrosulphuric acid* or *sulphuretted hydrogen*, and with the metals, various *sulphurets*. Many of its combinations are analogous to acids and bases, and are susceptible of combining with each other, forming compounds analogous to salts, and hence called by Berzelius *sulpho-salts*.

The minerals which are roasted to obtain sulphur sometimes contain arsenic; and hence sulphur is occasionally contaminated with this metal, and thereby rendered poisonous. The common English roll sulphur is said often to contain as much as a fifteenth of orpiment; but the accuracy of this statement may be deemed very doubtful.

The above description applies to sulphur generally; but in its several pharmaceutical states, of roll, sublimed, and washed sulphur, it presents modifications which require to be noticed.

Roll sulphur is in cylindrical sticks about an inch in diameter, and of various lengths. Though one of the purest forms of sulphur, it still contains about four parts in a thousand of hydrogen. The way in which it is obtained has already been described.

Sublimed sulphur, usually called *flowers of sulphur*, is in the form of a crystalline powder of a fine yellow colour. It is always contaminated with a little sulphuric acid which is formed, during its sublimation, at the expense of the oxygen of the air, contained in the subliming chambers. It is on this account that sublimed sulphur always reddens litmus; and if the acid be present in considerable quantity, it sometimes cakes. It may be freed from all acidity by ablution with hot water, when it becomes washed sulphur.

Washed sulphur is the only form of sulphur officinal in the United States Pharmacopœia, in which it is designated by the simple name, *Sulphur*. It was considered by the framers of that work to be the best medicinal form of this substance; and, therefore, the only one which should be used for internal exhibition. It is placed in the list of the Materia Medica in our national work, but the British Colleges give directions for preparing it. The process of the Dublin College, which appears to be the most eligible, is to pour warm water on sublimed sulphur, and to continue the washing as long as the water, when poured off, continues to be impregnated with acid, which may be known by the test of litmus. The sulphur is then dried on bibulous paper. The directions of the London and Edinburgh Colleges do not materially differ from those of the Dublin. Washed sulphur has the general appearance of sublimed sulphur; but if properly prepared it does not affect litmus, and undergoes no change by exposure to the atmosphere.

Medical Properties and Uses. Sulphur is laxative and diaphoretic. It evidently passes off by the pores of the skin; as is shown by the fact, that silver worn in the pockets of patients under a course of it, becomes blackened with a coating of sulphuret. As a laxative it is gentle in its operation, unless it contain a good deal of acid, when it causes griping; and the liability of the sublimed sulphur to contain acid, renders it less eligible for exhibition than the washed sulphur, from which all acidity is removed. The diseases in which sulphur is principally used, are hemorrhoidal affections, chronic rheumatism and catarrh, atonic gout, asthma, and other affections of the respiratory organs unattended with acute inflammation. It is also much employed, both internally and externally, in cutaneous affections, especially in scabies, for the cure of which it is considered a specific. The dose is from one to three drachms, mixed with syrup or molasses, or taken in milk. It is very often combined with supertartrate of potassa, or magnesia.

Sulphur is consumed in the arts, principally in the manufacture of gunpowder and sulphuric acid.

TABACUM. *U.S.*

Tobacco.

"Nicotiana tabacum. Folia. *The leaves.*" *U.S.*

Off. Syn. TABACI FOLIA. Nicotiana Tabacum. Folia exsiccata. *Lond.;* NICOTIANÆ TABACI FOLIA. *Ed.;* NICOTIANA TABACUM. Folia. *Dub.*

Tabac, *Fr.;* Tabak, *Germ.;* Tobacco, *Ital.;* Tabaco, *Span.*

Nicotiana. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Solaneæ.

Gen. Ch. Corolla funnel-shaped, with the border plaited. *Stamens* inclined. *Capsules* two-valved, two-celled. *Willd.*

Nicotiana Tabacum. Willd. *Sp. Plant.* i. 1014; Bigelow, *Am. Med. Bot.* ii. 171; Woodv. *Med. Bot.* p. 208. t. 77. The tobacco is an annual plant, with a large fibrous root, and an erect, round, hairy, viscid stem, which branches near the top, and rises from three to six feet in height. The leaves are numerous, alternate, sessile and somewhat decurrent, very large, ovate lanceolate, pointed, entire, slightly viscid, and of a pale green colour. The lowest are often two feet long, and four inches broad. The flowers are disposed in loose terminal panicles, and are furnished with long, linear, pointed bractes at the divisions of the peduncle. The calyx is bell-shaped, hairy, somewhat viscid, and divided at its summit into five pointed segments. The tube of the corolla is twice as long as the calyx, of a greenish hue, swelling at top into an oblong cup, and ultimately expanding into a five-lobed, plaited, rose-coloured border. The whole corolla is very viscid. The filaments incline to one side, and support oblong anthers. The pistil consists of an oval germ, a slender style longer than the stamens, and a cleft stigma. The fruit is an ovate, two-valved, two-celled capsule, containing numerous reniform seeds, and opening at the summit.

Although the original locality of this plant is not settled to the satisfaction of all botanists, there is good reason to believe that it is a native of tropical America, where it was found by the Spaniards upon their arrival. It is at present cultivated in most parts of the world, and nowhere more abundantly than within the limits of the United States. We seldom, however, see it north of Maryland. Virginia is, perhaps, the region of the world most celebrated for its culture. The young shoots, produced from seeds thickly sown in beds, are transplanted into the fields during the month of May, and set in rows with an interval of three or four feet between the plants. Through the whole period of its growth, the crop requires constant attention. The development of the leaves is promoted by removing the top of each plant, and thus preventing it from running into flower and seed. The harvest is in August. The ripe plants having been cut off above their roots, are dried under cover, and then stripped of their leaves, which are tied in bundles, and packed in hogsheads.

Two varieties of this species are mentioned by authors, one with narrow, the other with broad leaves; but they do not differ materially in properties. Great diversity in the quality of tobacco is produced by difference of soil and mode of cultivation; and several varieties are recognised in commerce. Other species of Nicotiana are also cultivated, especially the *N. rustica* and *N. paniculata*, the former of which is said to have been the first introduced into Europe, and is thought to have been cultivated by the aborigines of this country, as it is naturalized near the borders of some of our small northern lakes. The *N. quadrivalvis* of Pursh affords tobacco to the Indians of the Missouri and Columbia rivers; and the *N. fruticosa*, a native of China, was probably cultivated in Asia before the discovery of this continent by Columbus.

Properties. Tobacco, as it occurs in commerce, is of a yellowish-brown colour, a strong narcotic penetrating odour which is less obvious in the fresh leaves, and a bitter nauseous and acrid taste. These properties are imparted to water and alcohol. They are destroyed by long boiling; and the extract is therefore feeble or inert. An elaborate analysis of tobacco was made by Vauquelin, who discovered in it, among other ingredients, an acrid, volatile, colourless principle, slightly soluble in water, very soluble in alcohol, and supposed at one time to be the active principle of the leaves. It was separated by a very complicated process, and received the name of *nicotin*, which, however, has been subsequently applied to a different principle. An analogous substance was procured by Hermstadt, by simply distilling water from tobacco, and allowing the liquor to stand for several days. A white crystalline matter rose to the surface, which, upon being removed, was found to have the odour of tobacco, and its influence on the system. In solubility it agreed with the nicotin of Vauquelin, and like it was neither alkaline nor acid. Acetate of lead and nitrate of mercury precipitated it from its aqueous solution, infusion of galls from its solution in alcohol. It melted at a moderate heat, and was slowly volatilized. In the dose of a grain it produced nausea, retching, and vertigo; and excited sneezing when applied in minute quantity to the nostrils. It was called *nicotianin* by Hermstadt, and appears to partake of the nature of the volatile oils. More recently, two German chemists, Posselt and Reimann, have analyzed tobacco, and obtained some interesting results. According to these chemists, 10,000 parts of the fresh leaves contain 6 parts of an alkaline principle, which they call *nicotin*, 1 of the *nicotianin* of Hermstadt, 287 of slightly bitter extractive, 174 of gum mixed with a little malate of lime, 26.7 of green resin, 26 of albumen, 104.8 of a substance analogous to gluten, 51 of malic acid, 12 of malate of ammonia, 4.8 of sulphate of potassa, 6.3 of chloride of potassium, 9.5 of potassa, which was combined in the leaves with malic and nitric acids, 16.6 of phosphate of lime, 24.2 of lime which had been combined with malic acid, 8.8 of silica, 496.9 of lignin, traces of starch, and 8828 parts of water. (*Berzelius, Trait. de Chim.*)

Nicotin, or, as it should be called, *nicotia*, when perfectly pure, is liquid, transparent, colourless, of an odour somewhat like that of tobacco, but acrid, pungent, and disagreeable, and of an acrid, burning, durable taste. At 212° it diffuses white vapours in the air, but requires a much higher temperature for ebullition. Upon exposure it becomes brown and thicker, and is partially decomposed. It is inflammable, but does not burn readily unless with the aid of a wick. It is soluble in water in all proportious, and is readily soluble in ether. It restores the blue colour of litmus paper reddened by acids, and colours turmeric paper brown. It is consequently alkaline. On the animal economy it acts as a violent poison. A single drop is sufficient to destroy a dog. The salts of nicotin have a burning and acrid taste, with the flavour of tobacco. They are colourless, and for the most part soluble in alcohol and water, but insoluble in ether. To obtain nicotin, dried tobacco leaves are boiled in water acidulated with sulphuric acid, the decoction is evaporated by a gentle heat, and the residue treated with alcohol of the sp. gr. 0.848. The alcoholic solution of sulphate of nicotin thus obtained, is concentrated by distillation, then mixed with hydrate of magnesia or lime, and again distilled. The product of the distillation is a solution of nicotin and ammonia. This is agitated with ether, to which it yields a part of the nicotin. The solution separated from the ether is added to the residue contained in the root, and again distilled. The product yields to ether a fresh portion of nicotin; and the operation is repeated till the residue in the retort loses its acrimony, retaining only a bitter taste. The ethereal solution is deprived of water by the chloride of calcium, and then distilled. The ether first passes over, and afterwards the nicotin, when the temperature of the retort exceeds 212°. Thus obtained, nicotin has the consistence of honey, and a brown colour. To obtain it quite pure it should be redistilled by means of an oil bath, at the temperature of about 284°. It may be obtained by other processes. It exists in tobacco in very small proportion, constituting only one part in one thousand of the dry leaves. Buchner found it also in the seeds.

Nicotianin is the odorous principle of tobacco. Posselt and Reimann prepared it by distilling six pounds of the fresh leaves with twelve pounds of water, till one half of the liquid passed over, then adding six pounds more of water, and again distilling, and repeating this process three times. The nicotianin was obtained to the amount of eleven grains, floating on the surface of the water. It was a fatty substance, having the smell of tobacco-smoke, and an aromatic somewhat bitter taste. It was volatilizable by heat, insoluble in water, soluble in alcohol and ether, and not affected by the dilute acids, but dissolved by the solution of potassa.

When distilled at a temperature above that of boiling water, tobacco affords an empyreumatic oil, which Mr. Brodie has proved to be a most virulent poison, and which probably holds the volatile acrid principle of this narcotic in solution. A single drop of the oil injected into the rectum of a cat occasioned death in about five minutes, and double the quantity administered in the same manner to a dog was followed by the same result. This oil is of a dark brown colour, of an acrid taste, and has a very peculiar smell, exactly resembling that of tobacco pipes, which have been much used.

Medical Properties and Uses. Tobacco unites with the powers of a sedative narcotic, those of an emetic and diuretic; and produces these effects to a greater or less extent to whatever surface it may be applied. In addition, when snuffed up the nostrils, it excites violent sneezing and a copious secretion of mucus; when chewed, it irritates the mucous membrane of the mouth, and increases the flow of saliva; and when injected into the rectum, it operates as a cathartic. Very moderately taken, it quiets restlessness, calms mental and corporeal inquietude, and produces a state of general languor or repose, which has great charms for those habituated to the impression. In larger quantities, it gives rise to confusion of the head, vertigo, stupor, faintness, nausea, vomiting, and general debility of the nervous and circulatory functions, which, if increased, eventuates in alarming and even fatal prostration. The symptoms of its excessive action are severe retching, with the most distressing and continued nausea, great feebleness of pulse, coldness of the skin, fainting, and sometimes convulsions. It probably operates both through the medium of the nervous system, and by entering the circulation. As its local action is stimulant, we can thus account for the fact, that it excites the function of the kidneys, at the same time that it reduces the nervous and secondarily the arterial power. The experiments of Brodie lead to the inference that the function of the heart is affected by tobacco, through the medium of the nervous system; for in a decapitated animal in which the circulation was sustained by artificial respiration, the infusion injected into the rectum did not diminish the action of the heart; while on the contrary this organ almost immediately ceased to contract when an equal dose of the poison was administered to a healthy animal. Mr. Brodie observed a remarkable difference between the operation of the infusion and that of the empyreumatic oil. After death from the former the heart was found completely quiescent, while it continued to act with regularity for a considerable time after apparent death from the latter. We may infer from this fact, either that there are two poisonous principles in tobacco, or that a new narcotic product is formed during its destructive distillation.

The use of tobacco was adopted by the Spaniards from the American Indians. In the year 1560 it was introduced into France, by the ambassador of that country at the court of Lisbon, whose name—Nicot—has been perpetuated in the generic title of the plant. Sir Walter Raleigh is said to have introduced the practice of smoking into England. In the various modes of smoking, chewing, and snuffing, the drug is now extensively consumed in every country on the globe. It must have properties peculiarly adapted to the propensities of our nature, to have thus surmounted the first repugnance to its odour and taste, and to have become the passion of so many millions. When employed in excess it enfeebles the digestive powers, produces emaciation and general debility, and lays the foundation of serious disorders of the nervous system.

Its remedial employment is less extensive than would naturally be inferred from the variety of its powers. The excessive and distressing nausea which it is apt to occasion, interferes with its internal use; and it is very seldom administered by the stomach. As a narcotic it is employed chiefly to produce relaxation in spasmodic affections. For this purpose, the infusion or smoke of tobacco, or the leaf in substance in the shape of a suppository, is introduced into the rectum in cases of strangulated hernia, obstinate constipation from spasm of the bowels, and retention of urine from a spasmodic stricture of the urethra. For a similar purpose, the powdered tobacco, or common snuff, mixed with simple cerate, as recommended by the late Dr. Godman, is sometimes applied to the throat and breast in cases of croup; and Dr. Chapman has directed the smoking of a cigar in the same complaint, with decided benefit. One of the worst cases of spasm of the rima glottidis which we have seen, and which resisted powerful depletion by the lancet, yielded to the application of a tobacco cataplasm to the throat. A similar application to the abdomen is highly recommended in painters' colic. Tetanus is said to have been cured by baths made with the decoction of the fresh leaves. The relaxation produced by smoking, in a person unaccustomed to it, has been very happily resorted to by Dr. Physick, in a case of obstinate and long continued dislocation of the jaw; and the same remedy has frequently been found useful in the paroxysm of spasmodic asthma. As an emetic, tobacco is seldom or never employed, unless in the shape of a cataplasm to the epigastrium, to assist the action of internal medicines, in cases of great insensibility of stomach. As a diuretic it was used by Fowler in dropsy and dysury, but the practice is not often imitated. There is no better errhine than tobacco, for the ordinary purposes for which this class of medicines is employed. As a sialagogue, it is beneficial in rheumatism of the jaws, and often relieves toothach by its anodyne action. It is also used externally in the shape of cataplasm, infusion, or ointment, in cases of tinea capitis, psora, and some other cutaneous affections. The empyreumatic oil mixed with simple ointment, in the proportion of twenty drops to the ounce, has been applied with advantage, by American practitioners, to indolent tumours and ulcers; but in consequence of its liability to be absorbed, and to produce unpleasant effects on the system, it should be used with great caution. This remark is applicable to all the modes of employing tobacco; particularly to the injection of the infusion into the rectum, which has in more than one instance caused the death of the patient. It is even more dangerous than a proportionate quantity introduced into the stomach, as, in the latter case, the poison is more apt to be rejected.

Five or six grains of powdered tobacco will generally act as an emetic; but the remedy is not given in this shape. The infusion used in dropsy by Fowler, was made in the proportion of an ounce to a pint of boiling water, and given in the dose of sixty or eighty drops. The officinal infusion, which is employed for injection, is much weaker. (See *Infusum Tabaci.*) A wine and an ointment of tobacco are directed by the United States Pharmacopœia.

Gen. Ch. *Calyx* four-parted. *Petals* three. *Nectary* with two short bristles under the filaments. *Legume* filled with pulp. *Willd.*

Tamarindus Indica. Willd. *Sp. Plant.* iii. 577; Woodv. *Med. Bot.* p. 448. t. 161. The tamarind tree is the only species of this genus. It rises to a great height, sends off numerous spreading branches, and has a beautiful appearance. The trunk is erect, thick, and covered with a rough, ash-coloured bark. The leaves are alternate and pinnate, composed of many pairs of opposite leaflets, which are almost sessile, entire, oblong, obtuse, unequal at their base, about half an inch long, a sixth of an inch broad, and of a yellowish-green colour. The flowers, which are in small lateral racemes, have a yellowish calyx, and petals which are also yellow, but beautifully variegated with red veins. The fruit is a broad, compressed, reddish ash-coloured pod, very much curved, from two to six inches long, and with numerous brown, flat, quadrangular seeds, contained in cells formed by a tough membrane. Exterior to this membrane is a light-coloured acid pulpy matter, between which and the shell are several tough ligneous strings, running from the stem to the extremity of the pod, the attachment of which they serve to strengthen. The shells are very fragile, and easily separated.

The Tamarindus Indica appears to be a native of the East and West Indies, of Egypt, and Arabia, though believed by some authors to have been imported into America. De Candolle is doubtful whether the East and West India trees are of the same species. The pods of the former are much larger than those of the latter, and contain a greater number of seeds. At least such is the statement made by authors, who inform us that East India tamarinds contain six or seven seeds, those from the West Indies rarely more than three or four. We have found, however, in a parcel of the latter which we have examined, numerous pods with from eight to ten seeds, and the number generally exceeded four. The fruit is the officinal portion.

Tamarinds are brought to us chiefly, if not exclusively, from the West Indies, where they are prepared by placing the pods, previously deprived of their shell, in layers in a cask, and pouring boiling syrup over them. A better mode, sometimes practised, is to place them in stone jars, with alternate layers of powdered sugar. They are said to be occasionally prepared in copper boilers.

Properties. Fresh tamarinds, which are sometimes, though rarely, brought to this country, have an agreeable sour taste, without any mixture of sweetness. As we usually find them, in the preserved state, they form a dark-coloured adhesive mass, consisting of syrup mixed with the pulp, membrane, strings, and seeds of the pod, of a sweet acidulous taste. The seeds should be hard, clean, and not swollen, the strings tough and entire, and the smell without mustiness. From the analysis of Vauquelin it appears, that in 100 parts of the pulp of tamarinds, independently of the sugar added to them, there are 9.40 parts of citric acid, 1.55 of tartaric acid, 0.45 of malic acid, 3.25 of supertartrate of potassa, 4.70 of gum, 6.25 of jelly, 34.35 of parenchymatous matter, and 27.55 of water; so that the acidity is chiefly owing to the presence of citric acid. It is said that copper may sometimes be detected in preserved tamarinds, derived from the boilers in which they are occasionally prepared. Its presence may be ascertained by the reddish coat which it imparts to the blade of a knife immersed in the tamarinds.

Medical Properties and Uses. Tamarinds are laxative and refrigerant, and infused in water form a highly grateful drink in febrile diseases. Convalescents often find the pulp a pleasant addition to their diet, and useful by preserving the bowels in a loose condition. It is sometimes prescribed in connexion with other mild cathartics, and is one of the ingredients of the confection of senna. Though frequently prescribed with the infusion of senna to cover the taste of that medicine, it is said to weaken its purgative power; and the same observation has been made of its influence upon the resinous cathartics in general. From a drachm to an ounce or more may be taken at a dose.

TANACETUM. *U.S. Secondary.*

Tansy.

"Tanacetum vulgare. Herba. *The herb.*" *U. S.*

Off. Syn. TANACETI VULGARIS FLORES, FOLIA. *Ed.;* TANACETUM VULGARE. Folia. *Dub.*

Tanaisie, *Fr.;* Gemeiner Rheinfarrn, Wurmkraut, *Germ.;* Tanaceto, *Ital., Span.*

TANACETUM. *Sex. Syst.* Syngenesia Superflua.—*Nat. Ord.* Compositæ Corymbiferæ.

Gen. Ch. Receptacle naked. *Pappus* somewhat marginate. *Calyx* imbricate, hemispherical. *Corolla* rays obsolete, trifid. *Willd.*

Tanacetum vulgare. Willd. *Sp. Plant.* iii. 1814; Woodv. *Med. Bot.* p. 66. t. 27. This is a perennial herbaceous plant, rising two or three feet in height. The stems are strong, erect, obscurely hexagonal, striated, often reddish, branched towards the summit, and furnished with alternate, doubly pinnatifid leaves, the divisions of which are notched or deeply serrate. The flowers are yellow, and in dense terminal corymbs. Each flower is composed of numerous florets, of which those constituting the disk are perfect and five-cleft, those of the ray very few, pistillate, and trifid. The calyx consists of small, imbricated, lanceolate leaflets, having a dry scaly margin. The seeds are small, oblong, with five or six ribs, and crowned by a membranous pappus.

Tansy is cultivated in our gardens, and grows wild in the roads and old fields; but was introduced from Europe, where it is indigenous. It is in flower from July to September. The leaves are ordered by the Edinburgh and Dublin Colleges; but the flowers and seeds are not less effectual, and all are included in the directions of the United States Pharmacopœia.

There is a variety of the plant with curled leaves, which is said to be more grateful to the stomach than that above described, but has less of the peculiar sensible properties of the herb, and is probably less active as a medicine.

The odour of tansy is strong, peculiar, and fragrant, but much diminished by drying; the taste is warm, bitter, somewhat acrid, and aromatic. These properties are imparted to water and alcohol. The medical virtues of the plant depend on a bitter extractive and a volatile oil. The latter, when separated by distillation, has a greenish-yellow colour, and deposites camphor upon standing. The seeds contain the largest proportion of the bitter principle, and the least of volatile oil.

Medical Properties and Uses. Tansy has the medical properties common to the aromatic bitters; and has been recommended in intermittents, hysteria, amenorrhœa, and as a preventive of the arthritic paroxysms; but at present it is chiefly used as an anthelmintic, and in this country is scarcely employed, for any purpose, in regular practice. The seeds are said to be most effectual as a vermifuge. The dose of the powder is from thirty grains to a drachm two or three times a day; but the infusion is more frequently administered. A fatal case of poisoning with half an ounce of oil of tansy is recorded in the Medical Magazine for November, 1834. Frequent and violent clonic spasms were experienced, with much disturbance of respiration; and the action of the heart gradually became weaker till death took place from its entire suspension. No inflammation of the stomach or bowels was discovered upon dissection. (*Am. Journ. of the Med. Sci.* xvi. 256.)

W.

TAPIOCA. *U.S.*

Tapioca.

"Jatropha manihot. Radicis fæcula. *The fecula of the root.*" *U.S.*

Jatropha. *Sex. Syst.* Monœcia Monadelphia.—*Nat. Ord.* Euphorbiaceæ.

Gen. Ch. Male. *Calyx* none, or five-leaved. *Corolla* monopetalous, funnel-shaped. *Stamens* ten, alternately shorter. Female. *Calyx* none. *Corolla* five-petaled, spreading. *Styles* three, bifid. *Capsule* three-celled. *Seed* one. *Willd.*

Most if not all of the species of Jatropha are impregnated, like other plants of the natural family of Euphorbiaceæ, with an acrid, purging, poisonous principle. The seeds of the *J. Curcas*, which are known in Europe by the name of *purging nuts*, or *Barbadoes nuts*, have properties closely similar to those of the *Croton Tiglium* and *Ricinus communis*. They are blackish, oval, about eight lines long, flat on one side, convex on the other; and the two sides present a slight longitudinal prominence. Four or five of these seeds slightly roasted, and deprived of their envelope, are sufficient to purge actively; and in a large dose they are capable of producing fatal consequences. Their active principle is said to reside exclusively in the embryo. Upon pressure they yield an oil which has all the properties of the croton oil. We are not aware that they are employed in this country. The only species of Jatropha acknowledged as officinal in our Pharmacopœia is the *J. Manihot*, which yields the *tapioca* of the shops.

Jatropha Manihot. Willd. *Sp. Plant.* iv. 562. This is the *cassava* plant of the West Indies, the *mandioca* or *tapioca* of Brazil. It is a shrub about six or eight feet in height, with a very large, white, fleshy, tuberous root, which often weighs thirty pounds. The stem is round, jointed, and furnished at its upper part with alternate petiolate leaves, deeply divided into three, five, or seven oval lanceolate, very acute lobes, which are somewhat wavy upon their borders, of a deep green colour on their upper surface, glaucous and whitish beneath. The flowers are in axillary racemes.

The Jatropha Manihot is a native of South America, and is cultivated extensively in the West Indies, Brazil, and other parts of Tropical America, for the sake of its root, which is much employed as an article of food. The plant is of quick growth, and the root arrives at perfection in about eight months. There are two varieties, distinguished by the names of *sweet* and *acrid*. The root of the former may be eaten with impunity; that of the latter, which is most extensively cultivated, abounds in an acrid milky juice, which renders it highly poisonous if eaten in the recent state. Both contain a large proportion of starch. The root is prepared for use by washing, scraping, and grating or grinding it into a pulp, which, in the case of the acrid variety, is submitted to pressure so as to separate the deleterious juice. It is now in the state of meal or powder, which is made into bread, cakes, or puddings. As the acrid principle is volatile, the portion which may have remained in the meal is entirely dissipated by the heat employed in cooking. The preparation denominated tapioca among us is obtained from the expressed juice. This, upon standing, deposites a powder, which, after repeated washings with cold water, is nearly pure fecula. It is dried by exposure to heat, which renders it partly soluble in cold water, and enables it to assume the consistence by which it is characterized. When dried without heat, it is pulverulent, and closely resembles the fecula of arrow-root.

Tapioca is in the form of irregular, hard, white, rough grains, possessing little taste, partially soluble in cold water, and affording a fine blue colour when iodine is added to its filtered solution. Being nutritious, and at the same time easy of digestion, and destitute of all irritating properties, it forms an excellent diet for the sick and convalescent. It is prepared for use by boiling it in water. Lemon juice and sugar will usually be found grateful additions; and in low states of disease or cases of debility, it may be advantageously impregnated with wine and nutmeg or other aromatic.

A factitious tapioca is found in the shops, consisting of very small, smooth, spherical grains, and supposed to be prepared from potato starch. It is sold under the name of *pearl tapioca.* W.

TARAXACUM. *U.S.*

Dandelion.

"Leontodon taraxacum. Radix. *The root.*" *U.S.*

Leontodon. *Sex. Syst.* Syngenesia Æqualis.—*Nat. Ord.* Compositæ Cichoraceæ.

Gen. Ch. Receptacle naked. *Calyx* double. *Seed-down* stipitate, hairy. *Willd.*

Leontodon Taraxacum. Willd. *Sp. Plant.* iii. 1544; Woodv. *Med. Bot.* p. 39. t. 16. The dandelion is an herbaceous plant, with a perennial, fusiform root. The leaves, which spring immediately from the root, are long, pinnatifid, generally runcinate, with the divisions toothed, smooth, and of a fine green colour. The common name of the plant was derived from the fancied resemblance of its leaves to the teeth of a lion. The flower-stem rises from the midst of the leaves, six inches or more in height. It is erect, simple, naked, smooth, hollow, fragile, and terminated by a large golden-coloured flower, which closes in the evening, and expands with the returning light of the sun. The calyx is smooth and double, with the outer scales bent downwards. The florets are very numerous, ligulate, and toothed at their extremities. The receptacle is convex and punctured. The seed-down is stipitate, and at the period of maturity, is disposed in a spherical form, and is so light and feathery as to be easily borne away by the wind, with the seeds attached.

This species of Leontodon grows spontaneously in most parts of the globe. It is abundant in this country, adorning our grass-plats and pasture grounds with its bright yellow flowers, which, in moist places, show themselves with the first opening of spring, and continue to appear till near the close of summer. All parts of the plant contain a milky bitterish juice, which exudes when they are broken or wounded. The leaves, when very young, and blanched by the absence of light during their growth, are tender and not unpleasant to the taste, and on the continent of Europe are sometimes used as a salad. When older and of their natural colour, they are medicinal, and have been adopted as officinal by the Edinburgh and Dublin Colleges. The United States and London Pharmacopœias recognise only the root, which is by far the most efficacious part of the plant. It should be full grown when collected, and should be employed in the recent state, as it is then most active. It does not, however, as stated by Duncan, lose nearly all its bitterness by drying; and the root dug up in the warmer seasons might, if dried with care, be employed with propriety in the succeeding winter.

The fresh full-grown root of the dandelion is several inches in length, about as thick as the little finger, round and tapering, somewhat branched, of a light brown colour externally, whitish within, having a yellowish ligneous cord running through its centre, and abounding in a milky juice. In the dried state it is much shrunk, wrinkled longitudinally, brittle, and when broken presents a shining somewhat resinous fracture. It is without smell, but has a sweetish, mucilaginous, bitterish, herbaceous taste. Its active properties are yielded to water by boiling, and do not appear to be injured in the process. The milky juice, examined by John, was found to contain bitter extractive, gum, caoutchouc, saline matters, a trace of resin, and a free acid. Besides these ingredients, starch and saccharine matter exist in the root.

Medical Properties and Uses. Taraxacum is slightly tonic, diuretic, and aperient; and is thought to have a specific action upon the liver, exciting it when languid to secretion, and resolving its chronic engorgements. It has been much employed in Germany, and is a very popular remedy with many practitioners in this country. The diseases to which it appears to be especially applicable, are those connected with the derangement of the hepatic system, and of the digestive organs generally. In congestion and chronic inflammation of the liver and spleen, in cases of suspended or deficient biliary secretion, and in dropsical affections dependent on obstruction of the abdominal viscera, it is capable of doing much good, if applied with a due regard to the degree of excitement. Our own experience is decidedly in its favour. An irritable condition of the stomach and bowels, and the existence of acute inflammation, contra-indicate its employment.

It is usually given in the form of extract or decoction. (See *Extractum Taraxaci.*) Two ounces of the fresh root, or an ounce of the dried, previously bruised or sliced, may be boiled with a pint of water down to half a pint, and two fluidounces of the preparation given twice or three times a day. Supertartrate of potassa is sometimes added when an aperient effect is desired; and aromatics will occasionally be found useful in correcting a tendency to griping or flatulence.

Térébenthine, *Fr.;* Terpentin, *Germ.;* Trementina, *Ital., Span.*

The term *turpentine* is now generally applied to certain vegetable juices, liquid or concrete, which consist of resin combined with a peculiar essential oil, called the *oil of turpentine.* They are generally procured from different species of pine, though other trees afford products which are known by the same general title, as for instance, the *Pistacia Terebinthus*, which yields the Chian turpentine. Some of the French writers extend the name of turpentine to other juices consisting of resin and essential oil, as copaiba, balm of Gilead, &c. We shall describe particularly, in this place, only the officinal turpentines. A brief botanical view of the plants from which they are respectively derived, will be in accordance with the plan of the work.

Pinus. *Sex. Syst.* Monœcia Monadelphia.—*Nat. Ord.* Coniferæ.

Gen. Ch. Male. *Calyx* four-leaved. *Corolla* none. *Stamens* many. *Anthers* naked. Female. *Calyx* strobiles; scales two-flowered. *Corolla* none. *Pistil* one. *Nut* with a membranous wing. *Willd.*

The plants composing this genus are arranged by many botanists in three distinct genera, the *Pinus*, *Abies*, and *Larix*, of which the following characters are given by Lindley, in the Encyclopædia of Plants:—"1. Pinus.

Male. Anthers two-celled. *Female. Scales* in a conical cone, bracteate at base, digynous. *Pericarps* attached to the inside of scale, more or less winged, deciduous. *Stigmas* two or three-cleft. *Cotyledons* four to eight. —2. ABIES. The same as Larix, excepting its habit and stigma, which is that of Pinus. *Cotyledons* three to nine.—3. LARIX. *Male. Anthers* two-celled. *Female. Scales* imbricated, in a round cone, bracteate at base, digynous. *Pericarps* attached to the inside of scale, winged, deciduous. *Stigma* hemispherical, cupped, glandular. *Cotyledons* five to nine."—Though the distinction between these genera is sufficient to justify their establishment, we deem it best, in this work, to follow the authority of the Pharmacopœias which we have adopted as in some measure our standards, all of which adhere to the old genus Pinus. Besides the officinal species of pines, there is one, a native of this country, which affords a product considerably employed, though not recognised by the Pharmacopœias. The substance alluded to is the *essence of spruce*, prepared from the young branches of the *Pinus nigra* (Abies nigra), or *black spruce*, by boiling them in water, and evaporating the decoction. It is a thick liquid, having the colour and consistence of molasses, with a bitterish, acidulous, astringent taste. It is much used in the preparation of the beverage commonly known by the name of *spruce beer*, which is a pleasant and wholesome drink in summer, and useful in long sea-voyages as a preventive of scurvy.*

1. *Pinus palustris.* Willd. *Sp. Plant.* iv. 499.—*P. Australis.* Michaux, *N. Am. Sylv.* iii. 133. "Leaves in threes, very long; stipules pinnatifid, ramentaceous, persistent; strobiles sub-cylindrical, armed with sharp prickles."

This is a very large indigenous tree, growing in dry sandy soils from the southern part of Virginia to the Gulf of Mexico. Its mean elevation is sixty or seventy feet, and the diameter of its trunk about fifteen or eighteen inches for two-thirds of this height. The leaves are about a foot in length, of a brilliant green colour, and united in bunches at the ends of the branches. The names by which the tree is known in the Southern States, are *long-leaved pine*, *yellow pine*, and *pitch pine;* but the first is most appropriate, as the last two are applied also to other species. This tree furnishes by far the greater proportion of turpentine, tar, &c., consumed in the United States, or sent from this to other countries. (See *Pix Liquida.*)

2. *Pinus Tæda.* Willd. *Sp. Plant.* iv. 498; Michaux, *N. Am. Sylv.* iii. 156. "Leaves in threes, elongated, with elongated sheaths; strobiles oblong-conical, deflexed, shorter than the leaf; spines inflexed."

This is the *loblolly*, or *old field pine* of the Southern States. It is abundant in Virginia, where it occupies the lands which have been exhausted by cultivation. It exceeds eighty feet in height, has a trunk two or three feet in diameter, and expands into a wide-spreading top. The leaves are about six inches long, and of a light green colour. It yields turpentine in abundance, but less fluid than that which flows from the preceding species.

3. *Pinus sylvestris.* Willd. *Sp. Plant.* iv. 494; Woodv. *Med. Bot.* p. 1. t. 1; Michaux, *N. Am. Sylv.* iii. p. 125. "Leaves in pairs; rigid; strobiles ovate-conical, of the length of the leaves; scales echinate."

This species of pine, when of full size, is eighty feet high, with a trunk four or five feet in diameter. It inhabits the northern and mountainous parts of Europe. In Great Britain it is called the *wild pine*, or *Scotch fir;* the latter name having been applied to it from its abundance in the mountains of Scotland. It yields a considerable proportion of the common European turpentine.

---

* The following is the formula usually followed. Take of essence of spruce *half a pint;* pimento bruised, ginger bruised, hops, each, *four ounces;* water *three gallons.* Boil for five or ten minutes: then strain, and add of warm water *eleven gallons;* yeast *a pint;* molasses *six pints.* Mix and allow the mixture to ferment for twenty-four hours.

4. *Pinus Balsamea.* Willd. *Sp. Plant.* iv. 504.—*Abies Balsamifera,* Michaux, *N. Am. Sylv.* iii. p. 191. "Leaves solitary, flat, emarginate or entire, glaucous beneath, somewhat pectinate, sub-erect above, recurved spreading; cones cylindrical, erect; bractes abbreviate, obovate, conspicuously mucronate, sub-serrulate."

This is the *American silver fir*, inhabiting Canada, Nova Scotia, Maine, and the mountainous regions further to the south. It is an elegant tree, seldom rising more than forty feet in height, with a tapering trunk, and numerous branches which diminish in length in proportion to their height, and form an almost perfect pyramid. The leaves are six or eight lines long, inserted in rows on the sides and tops of the branches, narrow, flat, rigid, bright green on their upper surface, and of a silvery whiteness beneath. The cones are large, erect, nearly cylindrical, of a purplish colour, and covered with a resinous exudation which gives them a glossy, rich, and beautiful appearance. It is from this tree that the *Canada balsam* is obtained.

5. *Pinus Larix.* Willd. *Sp. Plant.* iv. 503; Woodv. *Med. Bot.* p. 7. t. 4.—*Larix Europæa.* De Cand.—*Larix communis.* Lindley. "Leaves fasicled, deciduous; cones ovate-oblong; margins of the scales reflexed, lacerated; bractes panduriform."

The *European larch* is a large tree inhabiting the mountains of Switzerland, Germany, and the East of France. It yields the *Venice turpentine* of commerce, and a peculiar sweetish substance, called in France *Briançon manna*, which exudes spontaneously, and concretes upon its bark.

Pistacia. See MASTICHE.

Pistacia Terebinthus. Willd. *Sp. Plant.* iv. 752; Woodv. *Med. Bot.* p. 29. t. 12. This is a small tree, with numerous spreading branches, bearing alternate, pinnate leaves, which consist of three or four pairs of ovate lanceolate, entire, acute, smooth, and shining leaflets, with an odd one at the end. The male and female flowers are diœcious, small, and in branching racemes. This is a native of Barbary and Greece, and flourishes in the islands of Cyprus and Chio, the latter of which has given its name to the turpentine obtained from the tree.

We shall treat of the several varieties of turpentine under distinct heads.

1. White Turpentine.

Térébenthine de Boston, *Fr.;*

The common *American* or *white turpentine*, (*Terebinthina* of the United States Pharmacopœia,) is procured chiefly from the *Pinus palustris*, partly also from the *Pinus Tæda*, and perhaps some other species inhabiting the Southern States. In former times, large quantities were collected in New-England; but the turpentine trees of that section of the Union are said to be nearly exhausted; and our commerce is almost exclusively supplied from North Carolina, and the south-eastern parts of Virginia. The following is the process for obtaining the turpentine as described by Michaux. During the winter months, excavations of the capacity of about three pints are made in the trunk of the tree three or four inches from the ground. Into these the juice begins to flow about the middle of March, and continues to flow throughout the warm season, slowly at first, rapidly in the middle of summer, and more slowly again in the autumnal months. The liquid is removed from these excavations as they fill, and transferred into casks, where it gradually thickens, and ultimately acquires a soft solid consistence. Very large quantities are thus annually procured, sufficient not only to supply the whole consumption of this country, but also to furnish a valuable export.

White turpentine, as found in our shops, has a peculiar somewhat aromatic odour, a warm pungent bitterish taste, and a white colour tinged with yellow. It is somewhat translucent, and of a consistence which varies with the temperature. In the middle of summer it is almost semi-fluid and very adhesive, though brittle; in the winter it is often so firm and hard, as to be incapable of being made into pills without heat. Exposed to the air it ultimately becomes perfectly hard and dry. In the recent state it affords about seventeen per cent. of essential oil.

2. COMMON EUROPEAN TURPENTINE.

Térébenthine de Bordeaux, Terebenthine commune, *Fr.;* Gemeiner Terpentin, *Germ.;* Trementina comune, *Ital.;* Trementina comun, *Span.*

This is the *Terebinthina Vulgaris* of the British Pharmacopœias. It is furnished by several species of pine; but most abundantly by the *Pinus sylvestris.* In the maritime districts of the south-west of France, especially in the department of the Landes, it is obtained largely from the *Pinus maritima.* The process consists simply in making incisions into the trunk, or removing portions of the bark, and receiving the juice which flows out in small troughs, or in holes dug at the foot of the tree. It is purified by heating and filtering it through straw, or by exposing it to the sun in a barrel, through holes in the bottom of which, the melted turpentine escapes. Thus prepared it is whitish, turbid, thickish, and separates, upon standing, into two parts, one liquid and transparent, the other of a consistence and appearance like those of thickened honey. It is scarcely ever given internally, but furnishes large quantities of oil of turpentine and resin. We do not import it into this country. The substance which the French call *galipot* or *barras*, is that portion of the turpentine which concretes upon the surface of the wounds, and is removed during the winter. (*Thenard.*) This, when purified by melting with water and straining, takes the name of *yellow* or *white pitch*, or *Burgundy pitch.* When turpentine has been deprived of its oil by distillation, the resin which remains is called *rosin*, and sometimes *colophony*, from the Ionian city of that name, where it was formerly prepared. It is the yellow resin, *Resina Flava*, of the London Pharmacopœia. White resin, *Resina Alba*, is prepared by incorporating this, while in fusion, with a certain proportion of water. Tar, *Pix Liquida*, is the turpentine extracted from the wood by a slow combustion, and chemically altered by the heat. Common pitch, *Pix Nigra* or *Resina Nigra*, is the solid residue left after the evaporation by boiling of the liquid parts of tar. (See these titles respectively.)

3. CANADIAN TURPENTINE.

Canada balsam; Baume de Canada, *Fr.;* Canadischer Balsam, Canadischer Terpentin, *Germ.;* Trementina del Canadà, *Ital.*

This is the product of the *Pinus Balsamea*, and is collected in Canada and the State of Maine. It is procured, according to Michaux, by breaking the vesicles which naturally form upon the trunk and branches, and receiving their liquid contents in a bottle. When fresh, it is colourless or slightly yellowish, transparent, of the consistence of thin honey, very tenacious, of strong agreeable odour, and a bitterish, somewhat acrid taste. By time and exposure it becomes more yellow and thicker, and at last assumes a solid consistence. It is usually brought into market in bottles, and is kept in the shops under the name of *Canada balsam*, or *balsam of fir*. In Europe, it is sometimes called *balm of Gilead*, from its supposed resemblance to that celebrated medicine. The term *balsam*, as at present understood, is improperly applied to it; as it contains no benzoic acid, and is in fact a true turpentine, consisting of resin and essential oil. There is reason to believe that *Strasburg turpentine* is sometimes sold for it in the shops.

4. Venice Turpentine.

Térébenthine de mélèze, Térébenthine de Venise, *Fr.;* Venetianischer Terpentin, *Germ.;* Trementina di Venezia, *Ital.;* Trementina de Venecia, *Span.*

This turpentine received its name from the circumstance that it was formerly an extensive article of Venetian commerce. It is procured in Switzerland, and the French province of Dauphiny, from the *Pinus Larix* or larch, which grows abundantly upon the Alps and the Jura mountains. The peasants bore holes into the trunk about two feet from the ground, and conduct the juice by means of wooden gutters into small tubs, placed at a convenient distance. It is afterwards purified by filtration through a leather sieve. Genuine Venice Turpentine is more fluid than the other varieties, of a yellowish or slightly greenish colour, a strong not disagreeable odour, and a warm bitterish and acrid taste. As found in our shops it is usually quite brown, and is said to be a factitious substance, prepared by dissolving resin in oil of turpentine. Dr. A. T. Thomson states that much of the Venice turpentine of the shops of London is obtained from America. It is probably the same preparation as that which passes under the name in this country.

5. Chian Turpentine.

Tèrèbenthine de Chio, *Fr.;* Cyprischer Terpentin, *Germ.;* Trementina Cipria, *Ital.*

This variety of turpentine is collected chiefly in the Island of Chio or Scio, by incisions made during the summer in the bark of the *Pistacia Terebinthus*. The juice flowing from the wounds, falls upon smooth stones placed at the foot of the tree, from which it is scraped with small sticks, and allowed to drop into bottles. The annual product of each tree is very small; and the turpentine, therefore, commands a high price even in the place where it is procured. Very little of it reaches this country. It is said to be frequently adulterated with the other turpentines. It is a thick, tenacious, pellucid liquid, of a slightly yellowish colour, a peculiar penetrating odour more agreeable than that of the other substances of the same class, and a mild taste with little bitterness. On exposure to the air it speedily thickens, and ultimately becomes concrete and hard, in consequence of the loss of its volatile oil.

Besides the turpentines mentioned, various others are noticed in books on materia medica, though not found in the shops of this country. There is the *Strasburg turpentine*, much used in France, and obtained from the *Pinus Picea*, (*Abies pectinata* of De Candolle,) or European silver fir, which grows on the mountains of Switzerland and Germany, and bears a close resemblance, as well in its appearance as its product, to the *Pinus Balsamea* of Canada; the *Damarra turpentine*, which speedily concretes into a very hard resin, and is derived from the *Pinus Damarra* of Lambert, the *Agathis Damarra* of Richard, growing in the East India islands; and the *Dombeya turpentine*, a glutinous milky looking fluid of a strong odour and aste, derived from the *Dombeya excelsa*, the *Araucaria Dombeyi* of Richrd, which inhabits Chili, and is said to be identical with the Norfolk Island pine. These, with one or two other turpentines scarcely known or having a doubtful claim to the title, are all that belong properly to this class of vegetable products.

General Properties. The turpentines resemble each other in odour and taste, though distinguished by shades of difference. Liquid at first, they become thick and gradually solid by exposure, in consequence partly of the volatilization, partly of the oxidation of their essential oil. They are rendered more liquid or softened by heat, and at a high temperature take fire, burning with a white flame and much smoke. Water extracts only a minute proportion of their volatile oil. They are wholly soluble in alcohol and ether, and readily unite with the fixed oils. They yield by distillation a volatile oil, well known as the *oil of turpentine*, and leave a residue consisting exclusively of resin. (See *Oleum Terebinthinæ* and *Resina.*) A minute proportion of succinic acid passes over with the oil. From the experiments of M. Faure of Bordeaux it appears, that some of the liquid turpentines, like copaiba, may be solidified by the addition of magnesia. (*Journ. de Chim. Med.* 1830, p. 94.)

Medical Properties and Uses. The effects of the turpentines upon the system are dependent entirely on their essential oil. They are stimulant, diuretic, anthelmintic, and in large doses laxative. Whether taken internally, or applied to the skin, they communicate a violet odour to the urine, and if continued for some time produce an irritation of the mucous membrane of the urinary passages, amounting frequently to strangury. The last effect is less apt to be experienced when they operate upon the bowels. Externally applied they act as rubefacients. Their medical virtues were known to the ancients. At present they are less used than formerly, having been superseded by their volatile oil. They are, however, occasionally prescribed in leucorrhœa, gleet, and other chronic diseases of the urinary passages; in piles and chronic inflammations or ulcerations of the bowels; in chronic catarrhal affections; and in various forms of rheumatism, especially sciatica and lumbago. The white turpentine is usually employed in this country.

They may be given in the shape of pill made with powdered liquorice root; or in emulsion with gum Arabic or yolk of egg, loaf sugar, and water; or in electuary formed with sugar or honey. Their dose is from a scruple to a drachm. In the quantity of half an ounce or an ounce, triturated with the yolk of an egg, and mixed with half a pint of mucilaginous liquid, they form an excellent injection in cases of ascarides, and of constipation attended with flatulence.

TESTA. *U.S.*

Oyster-shell.

Off. Syn. TESTÆ. *Lond.*

Ecailles des huîtres, *Fr.;* Austerschalen, *Germ.;* Gusci delle ostriche, *Ital.;* Cascaras, *Span.*

The common oyster is the *Ostrea edulis* of naturalists, an animal belonging to the class *Vermes*, order *Testacea*. It is found in many parts of the world, and is particularly abundant on our own coast, and in the bays of our large rivers. It consists of a soft pulpy portion, comprising the vital organs of the animal, enclosed in a hard bivalve shell, of the nature of mother-of-pearl. The meat of the oyster forms a very digestible and nutritious article of food, particularly suited to convalescents; but the shell only is officinal.

Properties. Oyster-shells are too familiarly known to require description. They are made up, like other mother-of-pearl shells, of alternate layers of earthy matter, and animal matter of the nature of coagulated albumen. According to the analysis of Bucholz and Brandes, their exact constituents are carbonate of lime 98.6, phosphate of lime 1.2, animal matter 0.5, alumina (accidental) 0.2=100.5. Thus it appears that the animal matter is present in but small amount. When calcined or burnt, the animal matter and carbonic acid are dissipated, and the shells are converted into a species of lime, called, in the arts, oyster-shell lime.

Pharmaceutical Uses. Oyster-shells require to be reduced to an impalpable powder, before they are fit for medicinal employment; and their preparation in this way constitutes their sole pharmaceutical use. When thus prepared, they form the *Testa Præparata*, under which head their medicina properties will be noticed.

TOLUTANUM. *U.S.*

Tolu.

"Myroxylon Toluiferum. *Richard.* Myroxylon Peruiferum. *Willd.* Succus. *The juice.*" *U. S.*

Off. Syn. BALSAMUM TOLUTANUM. Toluifera Balsamum. Balsamum. *Lond.*; TOLUIFERÆ BALSAMI BALSAMUM. *Ed.*; TOLUIFERA BALSAMUM. Resina. *Dub.*

Balsam of Tolu; Baume de Tolu, *Fr.*; Tolubalsam, *Germ.*; Balsamo del Tolu, *Ital.*; Balsamo de Tolu, *Span.*

MYROXYLON. See MYROXYLON.

Till recently, the tree from which this balsam is derived, retained the name of *Toluifera Balsamum*, given to it by Linnæus; but it is now admitted that the genus *Toluifera* was formed upon insufficient grounds; and botanists agree in referring the Tolu balsam tree to the *Myroxylon.* Ruiz, one of the authors of the Flora Peruviana, considers it identical with the *Myroxylon Peruiferum;* and his opinion has been adopted by some other writers. M. Achille Richard, however, thinks it a distinct species, and has appropriately denominated it *Myroxylon Toluiferum*, a title which is recognised in the Pharmacopœia of the United States. Sprengel and Humboldt also consider it a distinct species of Myroxylon. According to Richard, who had an opportunity of examining specimens brought from South America by Humboldt, the leaflets of the *M. Peruiferum* are thick, coriaceous, acute, and blunt at the apex, and all equal in size; while in the *M. Toluiferum* the leaflets are thin, membranous, obovate, with a lengthened and acuminate apex, and the terminal one is longest. The *M. Peruiferum* is found in Peru and the southern parts of New Granada; the *M. Toluiferum* grows in Carthagena, and abounds especially in the neighbourhood of Tolu. The wood of the latter species, according to Humboldt, is of a deep red colour, has a delightful balsamic odour, and is much used for building. It is not improbable, that the two balsams known in the shops by the respective names of Peru and Tolu, differ more in the mode by which they are procured, than in the character of the trees which afford them.

The balsam of Tolu is procured by making incisions into the runk of the tree. The juice as it exudes is received in vessels of various kinds, in which it is allowed to concrete. It is brought from Carthagena in calabashes, or baked earthen jars of a peculiar shape, and sometimes in glass vessels.

Properties. As first imported, it has a soft, tenacious consistence, which varies considerably with the temperature. By age it becomes hard and brittle like resin. It is shining, translucent, of a reddish or yellowish-brown colour, a highly fragrant odour, and a warm, somewhat sweetish and pungent, but not disagreeable taste. Exposed to heat, it melts, inflames, and diffuses, while burning, its own peculiar smell, united with that of benzoic acid. It is entirely dissolved by alcohol, and the essential oils. Boiling water extracts its benzoic acid. Distilled with water it affords a small proportion of volatile oil; and if the heat be continued, benzoic acid sublimes. Mr. Hatchet states, that when dissolved in the smallest quantity of solution of potassa, it loses its own characteristic odour, and acquires that of the clove-pink. Its ingredients are resin, benzoic acid, and volatile oil, the proportions of which vary in different specimens. Guibourt observed that it contains more benzoic acid, and is less odorous in the solid form; and thinks that the acid is increased at the expense of the oil. Trommsdorff obtained 88 per cent. of resin, 12 of acid, and only 0.2 of volatile oil.

Medical Properties and Uses. Tolu is a stimulant tonic, with a peculiar tendency to the pulmonary organs. It is given with some advantage in chronic catarrh and other pectoral complaints, in which a gently stimulating expectorant is demanded; but should not be prescribed until after the reduction of inflammatory action. Independently of its medical virtues, its pleasant flavour renders it a popular ingredient of expectorant mixtures. Old and obstinate coughs are said to be sometimes greatly relieved by the inhalation of the vapour proceeding from an ethereal solution of this balsam.

From ten to thirty grains may be given at a dose, and frequently repeated. The best form of administration is that of emulsion, made by triturating the balsam with mucilage of gum Arabic and loaf sugar, and afterwards with water.

TORMENTILLA. *U.S. Secondary.*

Tormentil.

"Tormentilla erecta. Radix. *The root.*" *U.S.*

Off. Syn. TORMENTILLÆ RADIX. Tormentilla officinalis. Radix. *Lond.;* TORMENTILLÆ ERECTÆ RADIX. *Ed.;* TORMENTILLA OFFICINALIS. *Dub.*

Tormentille, *Fr.;* Tormentillwurzel, *Germ.;* Tormentilla, *Ital.;* Tormentila, *Span.*

TORMENTILLA. *Sex. Syst.* Icosandria Polygynia.—*Nat. Ord.* Rosaceæ.

Gen. Ch. Calyx eight-cleft. *Petals* four. *Seeds* roundish, naked, affixed to a small, juiceless receptacle. *Willd.*

By some modern writers this genus is united with the *Potentilla*, from which it differs only in having eight instead of ten divisions of the calyx, and four instead of five petals.

Tormentilla erecta. Willd. *Sp. Plant.* ii. 1112; Woodv. *Med. Bot.* p. 503. t. 181.—*T. Officinalis.* Smith, *Flor. Brit.; Pharm. Lond.*—*Poten-*

tilla Tormentilla. Nestler, *Monograph. des Potentilles.* The tormentil, or septfoil, is a small perennial plant, very common throughout Europe. The stems, which rise about six or eight inches in height, from a woody root, are slender, more or less erect, branching towards the top, and furnished with sessile leaves, which on the stalk usually consist of seven, on the branches of five, digitate, elliptical, villous, deeply serrated leaflets, three of which are larger than the others. The flowers are small, yellow, and solitary upon axillary peduncles. All parts of the plant are astringent, especially the root, which is the part employed. It is gathered in spring.

Properties. The root of tormentil is cylindrical or roundish, rather larger above than at the lower extremity, an inch or two in length, about the thickness of the finger, knotty, sometimes contorted, brown or blackish externally, and reddish within. It has a slight aromatic odour, and a very astringent taste. Tannin is an abundant constituent. There is also a red colouring principle, soluble in alcohol, but insoluble in water. The root is said to be used for tanning leather in the Orkneys and Western Islands of Scotland, and for staining leather red by the Laplanders. It yields all its medical virtues to boiling water.

Medical Properties and Uses. Tormentil is a simple and powerful astringent, applicable to all cases of disease in which this class of medicines is indicated. We seldom, however, employ it in this country, having indigenous plants of equal virtue. It may be given in substance, decoction, or extract. The dose of the powder is from thirty grains to a drachm. Sumac vènèneux, *Fr.;* Gift-Sumach, *Germ.;* Albero del veleno, *Ital.*

RHUS. See RHUS GLABRUM.

Admitting, as appears generally to be done at present, that the *Rhus Toxicodendron* and *Rhus radicans* of Linnæus, are mere varieties of the same plant, there are three indigenous species of Rhus which possess poisonous properties—the one above mentioned, the *R. Vernix*, commonly known by the name of *swamp sumach*, or *poison sumach*, and the *R. pumilum* of the Southern States. Though the first only is designated in the Pharmacopœia, we shall briefly describe the three species, as their medical effects are probably similar, and their operation upon the system such that the plants should be known to every practitioner.

1. *Rhus radicans.* Willd. *Sp. Plant.* i. 1481; Bigelow, *Am. Med. Bot.* iii. 17.—*R. Toxicodendron.* Pursh, *Fl. Am. Sept.* p. 205. Though Elliott and Nuttall consider the *R. radicans* and *R. Toxicodendron* as distinct species, the weight of botanical authority is on the other side, and Bigelow declares that he has "frequently observed individual shoots from the same stock, having the characters of both varieties." The difference, however, in their appearance; is sufficiently striking to have led to the adoption of different common names, the R. radicans being usually called *poison vine*, and the R. Toxicodendron, *poison oak.* The former has a climbing stem,

rising to a great height upon trees, rocks, and other objects, to which it adheres by strong rooting fibres, which it throws out from its sides. The leaves, which stand upon long footstalks, are ternate, with broad ovate or rhomboidal, acute leaflets, smooth and shining on both sides, sometimes slightly hairy on the veins beneath, entire, or irregularly lobed and toothed. The flowers are small, greenish-white, diœcious, and grow in lateral, usually axillary panicles, or compound racemes. The male flowers have five stamens, and the rudiments of a style; the female, which are of only half the size and on a different plant, have abortive stamens, and a short erect style, standing on a roundish germ, and terminating in three stigmas. The fruit consists of roundish, pale-green or whitish berries.

The *R. Toxicodendron*, or poison oak, has the form of a shrub from one to three feet high, with leaflets angularly indented, and pubescent beneath. But this character of the foliage is probably not constant; and the stunted growth may be owing to peculiarities of situation. Dr. Bigelow states that the young plants of the R. radicans do not put forth rooting fibres until they are several years old, and that they are influenced in this respect by the contiguity of supporting objects.

This species of Rhus grows in woods, fields, and along fences, from Canada to Georgia. It flowers in June and July. When wounded, it emits a milky juice, which becomes black on exposure to the air, and leaves upon linen or other cloth a stain, which cannot afterwards be removed by washing with soap and water, or by alcohol either hot or cold, but deepens by age. It has been proposed as an indelible ink. Ether dissolves it.

The juice applied to the skin frequently produces inflammation and vesication; and the same poisonous property is possessed by a volatile principle which escapes from the plant itself, and produces in persons who come into its vicinity an exeedingly troublesome erysipelatous affection, particularly of the face. Itching, redness, a sense of burning, tumefaction, vesicatiou, and ultimate desquamation, are some of the attendants of this poisonous action. The swelling of the face is sometimes so great as almost entirely to obliterate the features. The effects are experienced soon after exposure, and usually begin to decline within a week. A light cooling regimen, with saline purgatives, and the local use of cold lead-water, are the best remedies. All persons are not equally liable to the affection, and the great majority are wholly unsusceptible of it from any ordinary exposure.

2. *Rhus Vernix.* Willd. *Sp. Plant.* i. 1479; Bigelow, *Am. Med. Bot.* i. 96. The *swamp sumach* is a beautiful shrub or small tree, usually ten or fifteen feet high, but sometimes rising thirty feet. The bark of the trunk is dark gray, of the branches lighter, of the extreme twigs and petioles beautifully red. The leaves are pinnate, with four or five pairs of opposite leaflets, and an odd terminal one. These are oblong or oval, entire or slightly sinuated, acuminate, smooth, and except the one at the end, nearly sessile. The flowers, as in the preceding species, are diœcious. They are very small, greenish, and arranged in loose axillary panicles. The berries are small, roundish, and greenish-white.

The tree grows in swamps and low grounds, from Canada to Carolina, and flowers in June and July. It is thought to be identical with a species of Rhus which grows in Japan, and furnishes a fine black varnish, much used in that country. Dr. Bigelow found that the opaque whitish juice which exudes from our native plant when wounded, and which becomes permanently black on exposure, may be made to afford a brilliant, glossy, durable varnish, by boiling it sufficiently before applying it.

The *Rhus Vernix* produces, much more powerfully than the *R. radicans*, the poisonous effects already described. Persons coming within its influence are much more apt to be affected with the poison, and generally suffer more severely. The whole body is sometimes enormously swollen, and the patient for many days scarcely able to move; but the complaint almost always spontaneously subsides without destroying life. As in the former instance, the susceptibility to the influence of the poison is exceedingly various, and some persons may handle the plant with perfect impunity.

3. *Rhus pumilum.* Michaux, *Flor. Americ.* i. 182. This is a southern species, growing in Upper Carolina, and not more than a foot in height. It is characterized by its pubescent branches and petioles; its pinnate leaves, with many pairs of oval, nearly acuminate, incised dentate leaflets, downy beneath; and by its silky fruit. According to Pursh it is the most poisonous of the genus.

It is probable that all parts of the Rhus radicans (R. Toxicodendron) are possessed of active properties; but the leaves only are directed in the Pharmacopœia, under the title of Toxicodendron. These are inodorous, have a mawkish acrid taste, and yield their virtues to water. The presence of tannin and gallic acid has been detected in them; but they have not been accurately analyzed.

Medical Properties and Uses. These leaves appear to be stimulant and narcotic, producing when swallowed more or less irritation of the stomach and bowels, and promoting the secretory function of the skin and kidneys. Orfila found them to act in the manner of the acrid poisons, and to produce a stupifying effect upon the nervous system. They were successfully used by Du Fresnoy, in France, in the cure of obstinate cutaneous diseases. Dr. Anderson, of Hull in England, effected cures with the medicine in several cases of palsy. A sense of heat and pricking, with irregular twitchings, were excited by it in the affected parts. Dr. Horsfield, and other physicians of this country, have used it in consumption and dropsy, but not with any very encouraging success.

The dose of the leaves recommended by Dr. Anderson, was half a grain or a grain three times a day; but this is much too small. Dr. Duncan gave it in larger doses, with little other than a laxative effect. Dr. Horsfield administered a teacupful of the strong infusion without disadvantage. In France the extract is recommended in doses of fifteen or twenty grains, repeated two or three times a day, and gradually increased to one or two drachms. Some of Du Fresnoy's patients took an ounce without effect. The probability is, that the active principle is volatile, and that the extract is less efficient than the leaves themselves. The risk of experiencing the poisonous effects of the plant upon the system, will probably prevent its extensive employment as a remedy, unless it should prove much more useful than the trials hitherto made give us reason to expect. W.

◆

TRAGACANTHA. *U.S.*

Tragacanth.

"Astragalus verus. Succus concretus. *The concrete juice.*" *U. S.*

Off. Syn. TRAGACANTHA. Astragalus verus. Gummi. *Lond.;* STRAGALI TRAGACANTHÆ GUMMI. Ex variis Tragacanthæ peciebus. *Ed.;* TRAGACANTHA GUMMI. ASTRAGALUS CRETIUS. Gummi. *Dub.*

Gomme Adraganthe, *Fr.;* Tragant, *Germ.;* Dragante, *Ital.;* Gomo tragacanto, *Span.*

ASTRAGALUS. *Sex. Syst.* Diadelphia Decandria.—*Nat. Ord.* Leguminosæ.

Gen. Ch. Legume two-celled, more or less gibbous, with the lower suture turned inwards. *Carina* blunt. *Loudon's Encyc. of Plants.*

Numerous species belonging to this genus yield a gummy matter having the properties of tragacanth. The drug known in commerce by that name has been ascribed, on the authority of Tournefort, to the *A. Tragacantha* of Linnæus (*A. Creticus* of Lamarck), which grows in Crete and Ionia; and on that of Olivier to the *A. verus* which inhabits Asia Minor, Armenia, and Northern Persia. Labillardière described a species by the name of *A. gummifer*, which he found growing on Mount Libanus in Syria, and from which tragacanth exudes, though not that of commerce. Siéber denies that any one of these species yields the officinal tragacanth, which he ascribes to the *A. aristatus* growing in Anatolia, especially upon Mount Ida, where the gum is most abundantly collected. This plant, however, is not the *A. aristatus* of Villars, which, according to Sibthorp, furnishes tragacanth in Greece. (*Merat* and *De Lens.*) The fact seems to be, that the commercial drug is collected from various sources; and it is affirmed that all the species of Astragalus with thorny petioles are capable of producing it. These form a natural group, and so closely resemble each other, that botanists have found some difficulty in distinguishing them. As the *A. verus* is designated in the Pharmacopœia of the United States, and that of the London College, we shall briefly describe it.

Astragalus verus. Olivier, *Voy. dans l'Empire Ottoman*, v. 342. pl. 44. This is a small shrub, not more than two or three feet high, with a stem an inch in thickness, and numerous very closely crowded branches, covered with imbricated scales, and spines which are the remains of former petioles. The leaves, which are little more than half an inch long, consist of several pairs of opposite, villous, stiff, pointed leaflets, with a midrib terminating in a sharp yellowish point. The flowers are papilionaceous, small, yellow, axillary, aggregate, and furnished with cottony bractes. This species yields the gum collected in Persia, and thence transmitted southward to India through Bagdad and Bassora, northward to Russia, and westward to Aleppo.

Tragacanth exudes spontaneously during the summer from the stems and branches, hardening as it exudes, and assuming various forms, according to the greater or less abundance of the juice.

Properties. It is in tortuous, vermicular filaments, rounded or flattened, rolled up or extended, of a whitish or yellowish-white colour, somewhat translucent, resembling horn in appearance. Sometimes the pieces are irregularly oblong or roundish, and of a slightly reddish colour. It is hard and more or less fragile, but difficult of pulverization, unless exposed to a freezing temperature, or thoroughly dried, and powdered in a heated mortar. The powder is very fine and white. Tragacanth has no smell, and very little taste. Its sp. gr. is 1.384. Introduced into water it absorbs a certain proportion of that liquid, swells very much, and forms a soft adhesive paste, but does not dissolve. If agitated with an additional quantity of water, this paste forms a uniform mixture; but in the course of one or two days the greater part separates and is deposited, leaving a portion dissolved in the supernatant fluid. Tragacanth is wholly insoluble in alcohol. It appears to be composed of two different constituents, one soluble in water and resembling if not identical with gum Arabic, the other capable of swelling in water, but not dissolving. The latter, which, according to Bucholz, constitutes 43 per cent. of tragacanth, is ranked by some among the peculiar proximate principles with the title of *tragacanthin.* It is probably identical with *bassorin.* It has the property of becoming blue with iodine, which is not the case with bassorin; but this property is ascribed to the presence of a small quantity of insoluble starch. According to M. Guerin, 100 parts of tragacanth contain 53.3 parts of Arabin or pure gum, 33.1 of bassorin and insoluble starch, and 11.1 of water, and yield when burned 2.5 parts of ashes. To separate the soluble entirely from the insoluble part, requires agitation with separate portions of water, which are to be decanted and filtered; and the process is to be continued till water ceases to dissolve anything. Berzelius considers tragacanth as a variety of mucilage. (See *Linum.*)

Medical Properties and Uses. Tragacanth is demulcent, but on account of its difficult solubility, is not often given internally. The great viscidity which it imparts to water, renders it useful for the suspension of heavy insoluble powders; and it is also employed in pharmacy to impart consistence to troches, for which it answers better than gum Arabic.

TRIOSTEUM. *U.S. Secondary.*

Fever-root.

"Triosteum perfoliatum. Radix. *The root.*" *U.S.*

TRIOSTEUM. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Caprifoliaceæ.

Gen. Ch. *Calyx* five-cleft, persistent, nearly the length of the corolla; segments linear, acute. *Corolla* tubular, five-lobed, subequal, base nectariferous, gibbous. *Stigma* somewhat five-lobed, capitate. *Berry* three-celled, three-seeded, crowned with the calyx. *Nuttall.*

Triosteum perfoliatum. Willd. *Sp. Plant.* i. 990; Bigelow, *Am. Med. Bot.* i. 90; Barton, *Med. Bot.* i. 59. This plant is indigenous and perennial. Several stems usually rise from the same root. They are simple, erect, round, hairy, fistulous, herbaceous, and from one to four feet high. The leaves are opposite, large, mostly connate, oval, acuminate, entire, abruptly narrowed at the base, and pubescent on their under surface. The flowers are of a dull purple colour, axillary, sessile, rarely solitary, sometimes in pairs, generally in triplets or five together in the form of whorls. The germ is inferior, and the style projects beyond the corolla, into the tube of which the stamens are inserted. The berry is oval and of a deep orange colour, containing three hard, bony seeds.

The *fever-wort*, *fever-root*, or *wild ipecac*, as this plant is variously called, though not very abundant, is found in most parts of the United States, preferring a limestone soil and shady situations. Its flowers appear in June. The whole plant has a bitter taste; but the root is most active, and is the only officinal part.

It is horizontal, long, about three-quarters of an inch in diameter, thicker and tuberculated near the origin of the stem, of a yellowish or brownish colour externally, whitish within, and furnished with fibres which may be considered as branches of the main root. When dry it is brittle and easily pulverized. It has a sickening odour and a bitter nauseous taste. Both water and alcohol take up its active properties, which are retained in the extract.

Medical Properties and Uses. Fever-root is cathartic, and in large doses emetic. The late Professor Barton observed it also to produce a diuretic effect. The bark of the root is the part which has been usually employed. In the quantity of twenty or thirty grains it ordinarily acts upon the bowels; and may be given alone or in combination with calomel at the commencement of fevers. The extract may be given in half the dose. W.

TRITICUM HYBERNUM. Seminum farina. *Dub.*

Wheat-flour.

Off. Syn. FARINA. Triticum hybernum. Farina. *Lond.*

Farine de froment, *Fr.;* Waizenmehl, *Germ.;* Farina di frumento, *Ital.;* Flor del trigo, Acemite, *Span.*

Triticum. *Sex. Syst.* Triandria Digynia.—*Nat. Ord.* Gramineæ.

Gen. Ch. *Calyx* two-valved, solitary, transverse, many-flowered, on a flexuose, toothed receptacle. *Rees's Cyclopædia.*

Triticum hybernum. Willd. *Sp. Plant.* i. 477. The *common winter wheat* has a fibrous root, and one or more erect, round, smooth, jointed stems, which rise from three to five feet in height, and are furnished with linear, pointed, entire, flat, many-ribbed, rough, somewhat glaucous leaves, and jagged bearded stipules. The flowers are in a solitary, terminal, dense, smooth spike, two or three inches long. The calyx is four-flowered, tumid, even, imbricated, abrupt, with a short compressed point. In the upper part of the spike it is more elongated; and in this situation the corolla is more or less awned. The grain is imbricated, in four rows.

The native country of wheat is unknown; but its cultivation is supposed to have spread from Sicily over Europe. It is now an object of culture in almost all countries which enjoy a temperate climate. Sown in the autumn, it stands the winter, and ripens its seed in the following summer. Numerous varieties have been produced by cultivation, some of which are usually described as distinct species. Among these may perhaps be ranked the *T. æstivum*, or spring wheat, distinguished by its long beards, and the *T. compositum*, or Egyptian wheat, by its compound spikes. It is asserted that the latter changes in Great Britain into the common single-spiked wheat. (*Loudon's Encyc.*) The seeds are too well known to need description. They are prepared for use by grinding and sifting, by which the interior farinaceous part is separated from the husk. The former is divided according to its fineness into different portions, but so far as regards its medical relations may be considered under one head, that of *farina* or *flour*. The latter is called *bran*, and constitutes from 25 to 33 per cent. according to the variety of wheat.

Flour is white, inodorous, and nearly insipid. Its chief constituents are starch, gluten, saccharine matter, and gum, the proportions of which are by no means constant. Vauquelin obtained, as an average product, from eight varieties of flour which he examined, 10.25 per cent. of water, 10.80 of gluten, 68.08 of starch, 5.61 of sugar, and 4.11 of gum. The ashes of wheat, which amount only to about 0.15 per cent., contain, according to Henry, superphosphates of soda, lime, and magnesia. The gummy substance found in wheat flour is not precisely identical with ordinary gum, as it contains nitrogen, and does not yield mucic acid by the action of nitric acid. The starch, which is by far the most abundant ingredient, is much employed in a separate state. (See *Amylum.*) The gluten, however, is not less important; as it is to the large proportion of this principle which wheat flour contains, that it owes its superiority over that of other grains for the preparation of bread. The *gluten* here alluded to is the substance first noticed as a distinct principle by Beccaria. It is the soft viscid fibrous mass which remains, when wheat flour, enclosed in a linen bag, is exposed to the action of a stream of water, and at the same time pressed with the fingers, till the liquor comes away colourless. But this has been ascertained to consist, in fact, of two different substances. An Italian chemist, of the name of Taddei, found that by boiling it in alcohol a portion was dissolved, while another portion remained unaffected. Considering these as distinct principles, he gave the name of *gliadine* to the soluble, and *zymome* to the insoluble portion. But he had been anticipated in his experiments by the German chemist Einhof, who appears to have established the fact, that the part of the glutinous mass left behind by alcohol is identical with *vegetable albumen*, while the dissolved portion only is strictly entitled to the appellation of *gluten*, which had been previously conferred on the whole mass. As these two principles are contained in numerous vegetable products, and as they are frequently referred to in this work, it is proper that they should be briefly noticed. They both contain nitrogen, and both, when left to themselves in a moist state, undergo putrefaction. From these circumstances, and from their close resemblance to certain proximate animal principles in chemical habitudes and relations, they are sometimes called in works on chemistry, *vegeto-animal substances*. They are separated from each other, as they exist in the mass originally denominated gluten, by boiling this mass with successive portions of alcohol, till the liquid, filtered while yet hot, ceases to become turbid on cooling. The gluten dissolves, and may be obtained by adding water to the solution, and distilling off the alcohol. Large cohering flakes float in the liquor, which, when removed, form a viscid elastic mass, consisting of the substance in question with some slight impurity. The part left behind by the alcohol is the albumen in a coagulated state.

Gluten, as thus procured, is a pale yellow, adhesive, elastic substance, which by drying becomes of a deeper yellow colour and translucent. It is almost insoluble in water, and quite insoluble in ether and in the oils both fixed and volatile. Hot alcohol dissolves it much more readily than cold; and from its solution in ordinary alcohol at the boiling temperature, it is precipitated unchanged when the liquor cools. It is soluble in the dilute acids, and in caustic alkaline solutions, in consequence of forming soluble compounds with the acids and alkalies. With the earths and metallic oxides it forms nearly insoluble compounds, which are precipitated when the earthy or metallic salts are added to the solution of gluten in liquid potassa. Corrosive sublimate precipitates it from its acid as well as alkaline solutions, and added in solution to moist gluten, forms with it a compound, which, when dry, is hard, opaque, and incorruptible. Gluten is also precipitated by infusion of galls. It bears a close resemblance to animal fibrin. Its name originated in its adhesive property. Gluten exists in most of the farinaceous grains, and in the seeds of some leguminous plants.

Vegetable albumen is destitute of adhesiveness, and when dried, is opaque, and of a white, gray, or brown colour. Before coagulation, it is soluble in water, but insoluble in alcohol. By heat it coagulates and becomes insoluble in water. It is dissolved by the solutions of the caustic alkalies. Most of the acids, if added to its solutions in excess, precipitate compounds of the acids respectively with the albumen, which, though soluble in pure water, are insoluble in that liquid when acidulated. It is not, however, precipitated by an excess of the phosphoric or acetic acid. Its relations with the earthy, and metallic salts are similar to those of gluten. Corrosive sublimate precipitates it from its solutions, except from those in phosphoric and acetic acids, and when added in a state of solution to moist albumen, forms with it a hard, opaque compound. It is also precipitated by infusion of galls. This principle derived its name from its very close resemblance to animal albumen. It is associated with gluten in most of the farinaceous grains, is a constituent of all the seeds which form a milky emulsion with water, and exists in all the vegetable juices which coagulate by heat.

The mixture of gluten and albumen which constitutes the gluten of Beccaria, exercises an important influence over starch, which, with the presence of water and the aid of a moderate heat, it converts partly into gum and partly into sugar. The production of saccharine matter in the germination of seeds, and in the formation of malt, which is an example of germination, is thus accounted for. The gluten itself becomes acid in the process, and loses the property of reacting on starch.

It is scarcely necessary to state, that bread is formed by making flour into a paste with the addition of yeast, setting it aside to ferment, and then exposing it to the heat of an oven. The fermentation excited by the yeast, is accompanied with the extrication of carbonic acid gas, which being retained by the tenacity of the gluten, forms innumerable little cells through the mass, and thus renders the bread light. It is important to recollect that common salt is always added; as this ingredient is incompatible with some of the substances which are occasionally directed to be made into pills with the crumb of bread.

Medical Properties and Uses. Wheat flour in its unaltered state is seldom used in medicine. It is sometimes sprinkled on the skin in erysipelatous inflammation, and various itching or burning eruptions, particularly the nettle-rash; though rye flour is generally preferred for this purpose.

In the state of bread it is much more employed. An infusion of toasted bread in water is a pleasant, somewhat nutritive drink, very well adapted to febrile complaints. Within our experience, no drink has been found more grateful in such cases than this infusion, sweetened with a little molasses, and flavoured by lemon-juice. Boiled with milk, bread constitutes the common suppurative poultice, which may be improved by the addition of a small proportion of perfectly fresh lard. Slices of it steeped in lead-water, or the crumb mixed with the fluid and confined within a piece of gauze, afford a convenient mode of applying this preparation to local inflammations. The crumb—*mica panis*—is, moreover, frequently used to give bulk to minute doses of very active medicines administered in the form of pill. It should be recollected, however, that the common salt which it contains is wholly incompatible with the nitrate of silver, which is frequently prescribed in this way, and the dose of which is so minute that no loss can be afforded.

Bran is sometimes used in decoction, as a demulcent in catarrhal affections and complaints of the bowels. It has, when taken in substance, laxative properties, and is used by some persons habitually and with great advantage to prevent costiveness. Bran bread, made from the unsifted flour, forms an excellent laxative article of diet in some dyspeptic cases. The action of the bran is probably altogether mechanical, consisting in the irritation produced upon the mucous membrane of the stomach and bowels by its coarse particles.

Tussilago. *Sex. Syst.* Syngenesia Superflua.—*Nat. Ord.* Compositæ Corymbiferæ.

Gen. Ch. Receptacle naked. *Pappus* simple. *Calyx* scales equal, as long as the disk, submembranaceous. *Florets of the ray* ligulate or toothless. *Willd.*

Tussilago Farfara. Willd. *Sp. Plant.* iii. 1967; Woodv. *Med. Bot.* p. 45. t. 18. Coltsfoot is a perennial herb, with a creeping root, which early in the spring sends up several leafless, erect, simple, unifloral scapes or flower-stems, five or six inches high, and furnished with appressed scale-like bractes of a brownish-pink colour. The flower, which stands singly at the end of the scape, is large, yellow, compound, with hermaphrodite florets in the disk, and female florets in the ray. The latter are numerous, linear, and twice the length of the former. The leaves do not make their appearance until after the flowers have blown. They are radical, petiolate, large, cordate, angular and toothed at the margin, bright green upon their upper surface, white and downy beneath.

The plant grows spontaneously both in Europe and North America. In this country it is found upon the banks of streams in the Middle and Northern States, and flowers in April. The whole of it is directed by the London College, the leaves and flowers only by those of Edinburgh and Dublin. The leaves are most frequently employed. They should be gathered after their full expansion, but before they have attained their greatest magnitude. (*London Dispensatory.*)

The flowers have an agreeable odour, which they retain after desiccation. The dried root and leaves are inodorous, but have a rough bitterish mucilaginous taste. Boiling water extracts all their virtues.

Medical Properties and Uses. Coltsfoot exercises little sensible influence upon the human system. It is, however, demulcent, and is sometimes used in chronic coughs, consumption, and other affections of the lungs. The expectorant properties which it was formerly thought to possess are not obvious. The leaves were smoked by the ancients in pulmonary complaints; and in some parts of Germany they are at the present time said to be substituted for tobacco. Cullen states that he found the expressed juice of the fresh leaves, taken to the extent of some ounces every day, beneficial in several cases of scrofulous sores; and a decoction of the dried leaves, as recommended by Fuller, answered a similar purpose, though it often failed to effect a cure.

The usual form of administration is that of decoction. An ounce or two of the plant may be boiled in two pints of water to a pint, of which a teacupful may be given several times a day. W.

ULMI CORTEX. *Lond.*

Elm Bark.

"Ulmus campestris. Liber. *The inner bark.*" *Lond.*

Ulmus. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Amentaceæ, *Juss.*; Ulmaceæ, *Mirbel, Lindley.*

Gen. Ch. Calyx five-cleft. *Corolla* none. *Capsule* (*Samara*) compressed, membranaceous. *Willd.*

Ulmus campestris. Willd. *Sp. Plant.* i. 1324; Woodv. *Med. Bot.* p. 710. t. 242. This species of elm is characterized by its doubly serrate leaves, unequal at their base, by its nearly sessile, clustered, pentandrous flowers, and its smooth fruit. It is a large tree, with strong spreading branches, and a rough, cracked bark. It is a native of Europe, where the wood is highly esteemed for certain purposes in the arts.

The inner bark of its young branches, which is the officinal portion, is thin, tough, of a brownish-yellow colour, inodorous, and of a mucilaginous bitterish taste. It imparts to water its taste and mucilaginous properties. The tincture of iodine indicates the presence of starch. A peculiar vegetable principle called *ulmin*, now believed to be a constituent of most barks, was first discovered in the matter which spontaneously exudes from the bark of the European elm. It is a dark-brown almost black substance, without smell or taste, insoluble in cold water, sparingly soluble in boiling water which it colours yellowish-brown, soluble in alcohol, and readily dissolved by alkaline solutions.

Medical Properties and Uses. The bark of the European elm is demulcent, and said to be diuretic. It has been recommended in cutaneous affections of the leprous and herpetic character; but is not at present very highly esteemed. It is usually given in the form of decoction, and must be long continued to produce beneficial results.

* * *

ULMUS. *U.S.*

Slippery Elm Bark.

"Ulmus fulva. Liber. *The inner bark.*" *U.S.*

Ulmus. See ULMI CORTEX.

Ulmus fulva. Michaux, *Flor. Americ.* i. 172.—*Ulmus rubra.* F. Andrew Michaux, *N. Am. Sylv.* iii. 89. The *slippery elm*, called also *red elm*, is a lofty tree, rising fifty or sixty feet in height, with a stem fifteen or twenty inches in diameter. The bark of the trunk is brown, that of the branches rough and whitish. The leaves are oblong ovate, acuminate, nearly equal at the base, unequally serrate, pubescent and very rough on both sides, four or five inches in length by two or three in breadth, and supported on short footstalks. The buds, a fortnight before their development, are covered with a dense russet down. The flowers, which appear before the leaves, are sessile, and in clusters at the extremity of the young shoots. The bunches of flowers are surrounded by scales, which are downy like the buds. The calyx also is downy. There is no corolla. The stamens are five in number, short, and of a pale rose colour. The fruit is a membranaceous capsule or samara, enclosing in the middle one round seed, destitute of fringe.

This species of elm is indigenous, growing in all parts of the United States north of Carolina, but most abundantly west of the Alleghany mountains. It flourishes in open, elevated situations, and requires a firm dry soil. From the white elm, *U. Americana*, it is distinguished by its rough branches, its larger, thicker, and rougher leaves, its downy buds, and the character of its flowers and seeds. Its period of flowering is in April. The inner bark is the part used in medicine, and is brought to the shops separated from the epidermis.

It is in long, nearly flat pieces, from one to two lines in thickness, of a fibrous texture, a tawny colour which is reddish on the inner surface, a peculiar sweetish not unpleasant odour, and a highly mucilaginous taste when chewed. By grinding, it is reduced to a light, grayish-fawn coloured powder. It abounds in mucilaginous matter, which it readily imparts to water.

Medical Properties and Uses. Slippery elm bark is an excellent demulcent, applicable to all cases in which this class of medicines is employed. It is especially recommended in dysentery, diarrhœa, and diseases of the urinary passages. Like the bark of the common European elm, it has been employed in leprous and herpetic eruptions; but neither in these nor in any other complaints does it probably exert any greater powers than such as belong to the demulcents generally. Its mucilage is highly nutritious; and we are told that it has proved sufficient for the support of life in the absence of other food. The instance of a soldier is mentioned, who lived for ten days in the woods on this bark and sassafras; and the Indians are said to resort to it for nutriment in extreme emergencies.

It is usually employed as a drink in the form of infusion. (See *Infusum Ulmi.*) The powder may be used, stirred in hot water, with which it forms a mucilage, more or less thick according to the proportion added. The bark also serves as an emollient application, in cases of external inflammation. For this purpose the powder may be formed into a poultice with hot water, or the bark itself may be applied, previously softened by boiling.

UVA PASSA. *U.S.*

Raisins.

"Vitis vinifera. Fructus siccatus. *The dried fruit.*" *U.S.*

Off. Syn. UVÆ PASSÆ. *Lond.;* VITIS VINIFERÆ FRUCTUS. Fructus siccatus. *Ed;* VITIS VINIFERA. Fructus siccatus. *Dub.*

Raisins secs, *Fr.;* Rosinen, *Germ.;* Uve passe, *Ital.;* Pasas, *Span.*

VITIS. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Vites.

Gen. Ch. *Petals* cohering at the apex, withering. *Berry* five-seeded, superior. *Willd.*

Vitis vinifera. Willd. *Sp. Plant.* i. 1180; Woodv. *Med. Bot.* p. 144. t. 57. The vine is too well known to require description. This particular species is distinguished by the character of its leaf, which is lobed, sinuated, and naked or downy. The leaves and tendrils are somewhat astringent, and were formerly used in diarrhœa, hemorrhages, and other morbid discharges. The juice which flows from the stem was also thought to be possessed of medicinal virtues, and the prejudice still lingers among the vulgar in some countries. The unripe fruit has a harsh sour taste, and yields by expression a very acid liquor, called *verjuice*, which was much esteemed by the ancients as a refreshing drink, when diluted with water. It contains malic and tartaric acids. The grape, when quite ripe, is among the most pleasant and grateful fruits brought upon the table, and is admirably adapted, by its refreshing properties, to febrile complaints. If largely taken, it proves diuretic and gently laxative. The ripe fruit differs from the unripe in containing more sugar and less acid, though never entirely destitute of the latter. A peculiar acid has been found in grapes called by some chemists *racemic acid*, by Berzelius *paratartaric acid*, from its resemblance to the tartaric, with which it agrees in composition, though differing from it in properties.

The plant is supposed to have been derived originally from Asia; but it has been cultivated in Europe and Northern Africa from the remotest antiquity; and is now spread over all the temperate civilized regions of the globe. The fruit is exceedingly influenced by soil and climate; and the varieties which have resulted from culture or situation are innumerable. Those which yield the raisins of commerce are confined to the basin of the Mediterranean.

Raisins are prepared either by partially cutting the stalk of the bunches before the grapes are perfectly ripe, and allowing them to dry upon the vine; or by picking them in their mature state, and steeping them for a short time previous to desiccation in an alkaline ley. Those cured by the first method are most highly esteemed.

Several varieties of raisins are known in commerce. The best of those brought to this country are the *Malaga* raisins, imported from Spain. They are large and fleshy, of a purplish-brown colour, and sweet agreeable taste. Those produced in Calabria are similar. The *Smyrna* raisins are also large, but of a yellowish-brown colour, slightly musky odour, and less agreeable flavour. They are originally brought from the coast of Syria. The *Corinthian raisins*, or *currants* as they are commonly called in this country, are small, bluish-black, of a fatty appearance, with a vinous odour, and a sweet slightly tartish taste. Their name was derived from the city in the vicinity of which they were formerly cultivated; at present they are procured chiefly from Zante, Cephalonia, and the other Ionian Islands. In the older Pharmacopœias they are distinguished by the title of *uvæ passæ minores*.

Raisins contain a larger proportion of sugar than recent grapes. This principle, indeed, is often so abundant that it effloresces on the surface, or concretes in separate masses within the substance of the raisin. The *sugar of grapes* differs slightly from that of the cane, and is said to be identical with that produced by the action of sulphuric acid upon starch. It is less sweet than common sugar, less soluble in cold water, much less soluble in alcohol, and forms a syrup of less consistence.

Medical Properties and Uses. The chief medical use of raisins is to flavour demulcent beverages. Taken in substance they are gently laxative; but are also flatulent and difficult of digestion; and when largely eaten sometimes produce unpleasant effects, especially in children.

Arbutus. *Sex. Syst.* Decandria Monogynia.—*Nat. Ord.* Ericeæ.

Gen. Ch. *Calyx* five-parted. *Corolla* ovate, with a mouth, pellucid at the base. *Berry* five-celled. *Willd.*

Arbutus Uva Ursi. Willd. *Sp. Plant.* ii. 618; Bigelow, *Am. Med. Bot.* i. 66.—*Arctostaphylos Uva Ursi.* Adanson; Sprengel.—The *uva ursi*, or *bearberry*, is a low evergreen shrub, with trailing stems, the young branches of which rise obliquely upwards for a few inches. The leaves are scattered, upon short petioles, obovate, acute at the base, entire, with a rounded margin, thick, coriaceous, smooth, shining, and of a deep green colour on their upper surface, paler and covered with a net-work of veins beneath. The flowers, which stand on short reflexed peduncles, are collected in small clusters at the ends of the branches. The calyx is small, five-parted, of a reddish colour, and persistent. The corolla is ovate or urceolate, reddish-white, or white with a red lip, transparent at the base, contracted at the mouth, and divided at the margin into five short reflexed segments. The stamens are ten, with short filaments and bifid anthers; the germ round, with a style longer than the stamens, and a simple stigma. The fruit is a small, round, depressed, smooth, glossy, red berry, containing an insipid mealy pulp, and five cohering seeds.

This humble but hardy shrub inhabits the northern latitudes of Europe, Asia, and America. It is also found in the lofty mountains of Southern Europe, such as the Pyrennees and the Alps; and, on the American continent, extends from Hudson's Bay as far southward as New Jersey, in some parts of which it grows in great abundance. It prefers a barren soil, flourishing on gravelly hills, and elevated sandy plains. The leaves are the only part used in medicine. They were formerly imported from Europe; but are now collected chiefly within our own limits; and the market of Philadelphia is supplied exclusively from New Jersey. They should be gathered in autumn, and the green leaves only selected.

In Europe the uva ursi is often adulterated with the leaves of the *Vaccinium Vitis Idæa*, which are wholly destitute of its peculiar properties, and may be distinguished by their rounder shape, their revolute edges which are sometimes slightly toothed, and the appearance of their under surface, which is dotted, instead of being reticulated as in the genuine leaves. These distinguishing characters are given, as parcels of the drug may sometimes reach this country from abroad. Leaves of the *Chimaphila umbellata* may sometimes be found among the uva ursi as it exists in our own markets. They may be readily detected by their greater length, their cuneiform lanceolate shape, and their serrate edges.

The leaves of the uva ursi are inodorous when fresh, but acquire a smell not unlike that of hay when dried and powdered. Their taste is bitterish strongly astringent, and ultimately sweetish. They afford a light brown, greenish-yellow powder. Water extracts their active principles, which are also soluble in officinal alcohol. Among their ingredients are tannin, bitter extractive, resin, gum, and gallic acid; and the tannin is so abundant that they are used for tanning in some parts of Russia. Neither this principle nor gallic acid exists in the leaves of the *Vaccinium Vitis Idæa.*

Medical Properties and Uses. Uva ursi is astringent and tonic, and is thought by some to have a specific direction to the urinary organs, for the complaints of which it is chiefly used. Others deny that it possesses any peculiar tendency of this kind, and ascribe all its effects to its astringent and tonic action. Though known to the ancients, it had passed into almost entire neglect, till its use was revived by De Haen about the middle of the last century. It has acquired some reputation as an antilithic, and has undoubtedly been serviceable in gravel, probably by giving tone to the digestive organs, and preventing the accumulation of principles calculated to produce a secretion or precipitation of calculous matter. In chronic nephritis it is also a popular remedy, and is particularly recommended when there is reason to conjecture the existence of ulceration in the kidneys, bladder, or urinary passages. Diabetes, catarrh of the bladder, incontinence of urine, gleet, leucorrhœa, and menorrhagia, are also among the diseases in which it has occasionally proved serviceable; and testimony is not wanting to its beneficial effects in phthisis pulmonalis. The dose of the powder is from a scruple to a drachm, to be repeated three or four times a day; but the form of decoction is usually preferred. (See *Decoctum Uvæ Ursi.*)

VALERIANA. *U.S.*

Valerian.

"Valeriana officinalis. Radix. *The root.*" *U. S.*

Off. Syn. VALERIANÆ RADIX. Valeriana officinalis (sylvestris.) Radix. *Lond.;* VALERIANÆ OFFICINALIS RADIX. *Ed.;* VALERIANA OFFICINALIS. Radix. *Dub.*

Valériane, *Fr.;* Wilde Baldrianwurzel, *Germ.;* Valeriana silvestre, *Ital.;* Valerian silvestre, *Span.*

VALERIANA. *Sex. Syst.* Triandria Monogynia.—*Nat. Ord.* Valerianeæ, *De Cand., Lindley.*

Gen. Ch. Calyx very small, finally enlarged into a feathery pappus. *Corolla* monopetalous, five-lobed, regular, gibbous at the base. *Capsule* one-celled. (*Loudon's Encyc. of Plants.*) *Stamens* exserted, one, two, three, and four. (*Nuttall.*)

Valeriana officinalis. Willd. *Sp. Plant.* i. 177; Woodv. *Med. Bot.* p. 77, t. 32. The *officinal*, or *great wild valerian*, is a large handsome herbaceous plant, with a perennial root, and an erect, round, channeled stem, from two to four feet high, furnished with opposite pinnate leaves, and terminating in flowering branches. The leaves of the stem are attached by short broad sheaths, the radical leaves are larger and stand on long footstalks. In the former the leaflets are lanceolate and partially dentate, in the latter elliptica and deeply serrate. The flowers are small, white or rose-coloured, odorous and disposed in terminal corymbs, interspersed with spear-shaped pointed bractes. The number of stamens in this species is three. The fruit is a capsule containing one oblong ovate, compressed seed.

The plant is a native of Europe, where it grows either in damp woods and meadows, or on dry elevated grounds. As found in these different situations, it presents characters so distinct as to have induced some botanists to make two varieties. That which affects a dry soil is not more than two feet high, and is distinguished by its narrow leaves. It is superior to the other variety in medicinal virtue.

The root, which is the officinal portion, is collected in spring before the stem begins to shoot, or in the autumn when the leaves decay. It should be dried quickly, and kept in a dry place. It consists of numerous long, slender, cylindrical fibres, issuing from a tuberculated head. As brought to this country it frequently has portions of the stem attached. The best comes from England.

Properties. The colour of the root is externally yellowish or brown, internally white. The powder is yellowish-gray. The odour, which in the fresh root is slight, in the dried is strong and highly characteristic, and though rather pleasant to many persons, is very disagreeable to others. Cats are said to be strongly attracted by it. The taste is at first sweetish, afterwards bitter and aromatic. Valerian yields its active properties to water and alcohol. Trommsdorf found it to consist of 1.2 parts of volatile oil; 12.5 of a peculiar extractive matter, soluble in water, insoluble in ether and alcohol, and precipitated by metallic solutions; 18.75 of gum; 6.25 of a soft odorous resin; and 63 of lignin. Of these constituents the most important is the essential oil, in which the virtues of the root chiefly reside. It is of a pale greenish colour, of the sp. gr. 0.934, with a pungent odour of valerian, and an aromatic taste. It becoms yellow and viscid by exposure. Trommsdorf has ascertained that it contains a peculiar volatile acid, upon which the name of *valerianic acid* has been conferred. This, when separated from the oil, is a colourless liquid, of an oleaginous consistence, having an odour analogous to that of valerian, and a very strong, sour, disagreeable taste. It combines with salifiable bases, forming salts, which retain, in a diminished degree, the odour of the acid. (*Journ. de Pharm.* xx. 316.)

The roots of the *Valeriana Phu* and *V. dioica* are said to be sometimes mingled with those of the officinal plant; but the adulteration is attended with no serious consequences, as though much weaker than the genuine valerian, they possess similar properties. The same cannot be said of the roots of several of the *Ranunculaceæ*, which, according to Ebermayer, are sometimes fraudulently substituted in Germany. They may be readily detected by their want of the peculiar odour of the officinal root.

Medical Properties and Uses. Valerian is gently stimulant, with an especial direction to the nervous system, but without narcotic effect. In large doses it produces a sense of heaviness and dull pain in the head. It is useful in cases of irregular nervous action, when not connected with inflammation or an excited condition of the system. Among the complaints in which it has been particularly recommended, are hysteria, hypochondriasis, epilepsy, hemicrania, and low forms of fever attended with restlessness, morbid vigilance, or other symptoms of nervous derangement. It has also been used in intermittents combined with Peruvian bark. At best, however, it is an uncertain remedy. It may be given in powder or infusion. In the latter form, it is said by Professor Jœrg of Leipsic, who has experimented with it, to be less apt to irritate the alimentary canal than when administered in substance. The dose of the powder is from thirty to ninety grains, repeated three or four times a day. The tincture is also officinal. As the virtues valerian reside chiefly in the volatile oil, the medicine should not be given in decoction or extract. The distilled water is used on the continent of Europe; and the volatile oil is occasionally substituted with advantage for the root. The dose of the oil is four or five drops.

VERATRUM. *Sex. Syst.* Polygamia Monœcia. — *Nat. Ord.* Junci, *Juss.;* Melanthaceæ, *R. Brown, Lindley.*

Gen. Ch. HERMAPHRODITE. *Calyx* none. *Corolla* six-petaled. *Stamens* six. *Pistils* three. *Capsules* three, many-seeded. MALE. *Calyx* none. *Corolla* six-petaled. *Stamens* six. *Pistils* a rudiment. *Willd.*

Botanists who reject the class *Polygamia* of Linnæus, place this genus in the class and order *Hexandria Trigynia*, with the following character. "Polygamous. *Corolla* six-parted, spreading, segments sessile and without glands. *Stamens* inserted upon the receptacle. *Capsules* three, united, many-seeded." *Nuttall.*

Besides the *Veratrum album*, and *V. viride*, which are officinal plants, another species—the *Veratrum Sabadilla*—is noticed in medical works. It is a Mexican plant, and is interesting chiefly as the source of a drug known by the name of *cevadilla.* This is the fruit of the plant, and consists of yellowish, inodorous, bitterish, oblong capsules, three or four lines in length, with three cells, each containing two black, elongated, pointed, somewhat wrinkled seeds, of an extremely acrid and even caustic taste. It is imported from Mexico, and is used chiefly for the preparation of veratria. It is the principal ingredient of the *pulvis Capucinorum*, sometimes used in Europe for the destruction of vermin in the hair. As an internal remedy it has been used in worms, and various nervous complaints; but its poisonous properties require that it should be employed with great caution. Externally applied, it is said to be corrosive.

Veratrum album. Willd. *Sp. Plant.* iv. 895; Woodv. *Med. Bot.* p. 754. t. 257. This is an herbaceous plant, with a perennial, fleshy, fusiform root, yellowish-white externally, pale yellowish-gray within, and beset with long cylindrical fibres of a grayish colour. The stem is three or four feet high, thick, round, erect, and furnished with alternate leaves, which are oval, acute, entire, plaited longitudinally, about ten inches long by five in breadth, of a yellowish-green colour, and embrace the stem at their base. The flowers are greenish, and arranged in a terminal panicle.

The white hellebore is a native of the mountainous regions of continental Europe, and abounds in the Alps and Pyrennees. All parts of the plant are said to be acrid and poisonous; but the root only is officinal. This is brought to us from Germany in the dried state, in pieces from one to three inches long by an inch or less in mean diameter, cylindrical or in the shape of a truncated cone, internally whitish, externally blackish, wrinkled, and rough with the remains of the fibres which have been cut off near their origin. Sometimes the fibres continue attached to the root. They are numerous, yellowish, and of the size of a crow's quill.

Properties. The fresh root has a disagreeable odour, which is lost by drying. The taste is at first sweetish, afterwards bitterish, acrid, burning, and durable. The powdered root is grayish. Analyzed by Pelletier and Caventou, white hellebore was found to contain an oily matter consisting of elaïn, stearin, and a volatile acid; supergallate of *veratria;* a yellow colouring matter; starch; gum; lignin; silica, and various salts of lime and potassa. The medicinal properties of the root reside in the *veratria*, which was first discovered in the seeds of the *Veratrum Sabadilla*, and probably exists in other plants belonging to the same family. It is combined in the native state with an excess of gallic acid. As it may possibly come into use as a substitute for the more or less uncertain remedies of which it is the active ingredient, it deserves a particular notice in this place.

The process originally employed for obtaining veratria is difficult and yields but a small product. The following is recommended by M. Couerbe. An alcoholic extract of cevadilla, obtained by treating this substance with boiling alcohol and evaporating the tincture, is to be boiled with water acidulated with sulphuric acid until the liquid ceases to receive colour, or till a mineral alkali introduced into it, no longer occasions any sign of precipitation. To the solution of impure sulphate of veratria thus obtained, a solution of potassa or ammonia is to be added, and the resulting precipitate is to be treated with boiling alcohol and animal charcoal. The alcoholic solution, being filtered and evaporated, will yield the veratria sufficiently pure for medical use. A drachm of it, in this state, may be procured from a pound of cevadilla. But M. Couerbe has shown, that, besides *veratria*, there are at least two other distinct principles in this product, one of which, possessing alkaline properties, he calls sabadilline (*sabadillia*), and the other he proposes to name *veratrin.* These are separated in the following manner. Into the solution of impure sulphate of veratria obtained in the above process, nitric acid is to be introduced by drops. This occasions an abundant precipitate, from which the clear liquor is to be decanted. A weak solution of potassa is then to be added to the liquor, and the precipitate which it produces is to be washed with cold water, and treated with boiling alcohol. The substance obtained by evaporating the alcohol yields the *sabadillia* to boiling water, which deposites it upon cooling—a substance called by M. Couerbe *resini-gum of sabadillia*, remaining in solution. If the residue of the substance treated as just mentioned with boiling water, be submitted to the action of ether, it yields to this liquid the proper *veratria* which may be obtained entirely pure by the spontaneous evaporation of the ether. The matter remaining undissolved is the resinous substance which M. Couerbe calls *veratrin.*

Veratria, when pure, is white, pulverulent, uncrystallizable, inodorous, extremely acrid, fusible by heat, scarcely soluble in cold water, soluble in a thousand parts of boiling water which it renders sensibly acrid, dissolved freely by alcohol, less so by ether, and capable of neutralizing the acids, with several of which, particularly the sulphuric and muriatic, it forms crystallizable salts.

Sabadillia is white, crystallizable, insupportably acrid, fusible by heat, readily soluble in hot water which deposites it upon cooling, very soluble in alcohol, and wholly insoluble in ether. It is capable of saturating the acids.

For practical purposes it is unnecessary to obtain these two principles in a separate state; and the impure veratria obtained by the process above described as that of M. Couerbe, possesses, in all probability, more fully the properties of white hellebore, than the alkali entirely pure. (*Journ. de Pharm.* xix. 527.)

Medical Properties and Uses. White hellebore is a violent emetic and cathartic, capable of producing dangerous and fatal effects when incautiously administered. Even in small doses it has sometimes occasioned severe vomiting, hypercatharsis with bloody stools, and alarming symptoms of general prostration. Applied externally upon a portion of the surface denuded of the cuticle, as upon ulcers for example, it gives rise to griping pain in the bowels, and sometimes violent purging. When snuffed up the nostrils, it occasions great irritation with violent sneezing, and its use in this way is not free from danger. It was employed by the ancients in dropsy, mania, epilepsy, leprosy, elephantiasis, and other obstinate disorders, not without occasional advantage; but the severity of its operation has led to its general abandonment as an internal remedy. It is sometimes used as an errhine, diluted with some mild powder, in cases of gutta serena and lethargic affections; and in the shape of decoction, or of ointment prepared by mixing the pulverized root with lard, has been found beneficial as an external application in the itch, and in other cutaneous eruptions. From the resemblance of its operation to that of the *eau medicinale d'Husson*, so celebrated for the cure of gout, it has been conjectured to be the chief constituent of that remedy—a reputation which has also been enjoyed by colchicum; and the existence of *veratria* in the two medicines, accounts for this coincidence. A mixture of the wine of white hellebore and the wine of opium, in the proportion of three parts of the former to one of the latter, was introduced into use by Mr. Moor of London as a substitute for the eau medicinale, and has been considerably employed in gouty and rheumatic affections.

In whatever way white hellebore is used, it requires cautious management. It has been given in doses varying from one grain to a scruple. Not more than two grains should be administered at first. When employed as an errhine it should be mixed with five or six parts of pulverized liquorice root or other inactive powder. Ten or twelve grains of the mixture may be snuffed up the nostrils at one time.

Veratria acts in a similar manner with the white hellebore, but is much more powerful. One-twelfth of a grain may be given in the form of pill or alcoholic solution, and repeated three or four times in the twenty-four hours, till it purges. Dr. Turnbull of London very highly recommends veratria as an external application in functional disorders of the heart, neuralgia, rheumatism, and different forms of dropsy. He says that when rubbed upon the sound skin, in the form of ointment, to the extent of six or eight grains a day, it calms irritation, removes pain, and exhilarates the spirits, at the same time not unfrequently inducing constipation, and in cases of serous effusion, acting as a powerful diuretic. It occasions, when thus applied, no other local irritation than a slight blush upon the skin, and a sense of warmth and tingling in the part, which extends over the whole body, when the system comes under its influence. To the denuded cutis, it proves too irritating to admit of its application. He uses an ointment made with lard in the proportion of from fifteen to forty grains of veratria to the ounce, and directs a portion of this of the size of a nut to be rubbed upon the skin daily. (*Am. Journ. of the Med. Sci.* xiv. 440.)

VERATRUM VIRIDE. *U.S.*

American Hellebore.

"Veratrum viride. Radix. *The root.*" *U.S.*

Veratrum. See VERATRUM ALBUM.

Veratrum viride. Willd. *Sp. Plant.* iv. 896; Bigelow, *Am. Med. Bot.* ii. 121. The American hellebore, known also by the names of *Indian poke*, *poke root*, and *swamp hellebore*, has a perennial, thick, fleshy root, the upper portion of which is tunicated, the lower solid and beset with numerous whitish fibres or radicles. The stem is annual, round, striated, pubescent, and solid, from three to six feet in height, furnished with bright green leaves, and terminating in a panicle of greenish-yellow flowers. The leaves gradually decrease in size as they ascend. The lower are from six inches to a foot long, oval, acuminate, plaited, nerved, and pubescent; and embrace the stem at their base, thus affording it a sheath for a considerable portion of its length. Those on the upper part of the stem, at the origin of the flowering branches, are oblong lanceolate. The panicle consists of numerous flowers distributed in racemes with downy peduncles. Each flower is accompanied with a downy pointed bracte much longer than its pedicel. There is no calyx, and the corolla is divided into six oval acute segments, thickened on the inside at their base, with the three alternate segments longer than the others. The six stamens have recurved filaments, and roundish two-lobed anthers. The germs are three, with recurved styles as long as the stamens. Some of the flowers have only the rudiments of pistils. Those on the upper end of the branchlets are barren, those on the lower portion fruitful. The fruit consists of three cohering capsules, separating at top, opening on the inner side, and containing flat imbricated seeds.

This indigenous species of Veratrum is found from Canada to Carolina, inhabiting swamps, wet meadows, and the banks of mountain streamlets. Early in the spring, before the stem rises, it bears a slight resemblance to the *Symplocarpus fœtidus*, with which it is very frequently associated; but the latter sends forth no stem. From May to July is the season for flowering.

The root of the American hellebore has a bitter acrid taste, leaving a permanent impression in the mouth and fauces. Though not hitherto chemically analyzed, it probably contains *veratria*. In sensible properties and medical effect, it bears so close a resemblance to the white hellebore, that a separate description is unnecessary. It may be safely substituted for the European root, in all cases in which the latter is employed, may be given in the same dose, and administered in a similar manner. It is, however, very little used in regular practice. (See *Veratrum Album.*) For an account of what may be said upon the medical properties and applications of the American hellebore, the reader is referred to a paper by Dr. Charles Osgood, in the *American Journal of the Medical Sciences*, vol. xvi. p. 296. It is stated by Dr. Osgood that our native hellebore differs from the European in being totally destitute of any laxative property.

Off. Prep. Unguentum Veratri Viridis, *U.S.* W.

VERBASCUM THAPSUS. Folia. *Dub.*

Mullein Leaves.

VERBASCUM. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Solaneæ.

Gen. Ch. Calyx five-parted. *Corolla* rotate, five-lobed, unequal. *Stamens* declined, bearded. *Stigma* simple. *Capsule* two-celled, valves inflected, many-seeded. *Nuttall.*

Verbascum Thapsus. Willd. *Sp. Plant.* i. 1001; Woodv. *Med. Bot.* p. 202. t. 75. This is a biennial plant, with an erect, round, rigid, hairy stem, which rises from three to six feet in height, and is irregularly beset with large sessile, oblong or oval, somewhat pointed leaves, indented at the margin, woolly on both sides, and decurrent at the base. The flowers are yellow, and disposed in a long, close, cylindrical, terminal spike.

The mullein is common throughout the United States, growing along the road-sides and in neglected fields, and springing up abundantly in newly cleared places, at the most remote distance from cultivation. It is nevertheless considered by many botanists as a naturalized plant, introduced originally from Europe, where it is also abundant. It flowers from June to August. The leaves and flowers have been employed; but the former only are directed by the Dublin College. Both have a slight, somewhat narcotic smell, which in the dried flowers becomes agreeable. Their taste is mucilaginous, herbaceous, and bitterish, but very feeble. They impart their virtues to water by infusion.

Medical Properties and Uses. They are demulcent and emollient, and are thought to possess anodyne properties, which render them useful in pectoral complaints. On the Continent of Europe, an infusion of the flowers strained, in order to separate the rough hairs, is considerably used in mild catarrhs. Dr. Home found a decoction of the leaves useful in diarrhœa. The leaves are also employed externally, steeped in hot water, as a feebly anodyne emollient. An ointment is prepared from them in the recent state, and used for the same purposes. It may be made in the same manner as ointment of stramonium, by boiling the leaves in lard. It will be found advantageous to moisten them with water previously to the boiling. W.

◆

VERONICA. *U.S. Secondary.*

Veronica.

"Veronica Virginica. Radix. *The root. U.S.*

Several species of Veronica, common to Europe and this country, have been medicinally employed, under the impression that they possessed alterative and antiscorbutic properties. Among these are the *Veronica officinalis* or speedwell, and *V. Beccabunga* or brooklime, the latter of which has but recently been discharged from the officinal catalogue of the Dublin College. None of them are now employed. The *Veronica Virginica* of Linnæus, the root of which is the officinal Veronica, has been separated from this genus by Mr. Nuttall, and erected into a new one with the title of Leptandra, which is now generally acknowledged. The proper name, therefore, of the plant under consideration, is *Leptandra Virginica.*

Leptandra. *Sex. Syst.* Diandria Monogynia.—*Nat. Ord.* Scrophularineæ.

Gen. Ch. Calyx five parted, segments acuminate. *Corolla* tubular-campanulate, border four-lobed, a little ringent, unequal, the lower lamina narrower. *Stamens* and at length the *pistil* much exserted; filaments below, and tube of the corolla pubescent. *Capsule* ovate, acuminate, two-celled, many-seeded, opening at the summit. *Nuttall.*

Leptandra Virginica. Nuttall, *Gen. of N. Am. Plants*, i. 7; Rafinesque, *Med. Flor.* vol. ii. This plant, sometimes called *Culver's physic*, has a perennial root, with an herbaceous stem three or four feet high, furnished with leaves in whorls, and terminating in a long spike of white flowers. A variety was seen by Pursh with purple flowers. This is described and figured as a distinct species by Rafinesque, under the title of *L. purpurea.*

The plant grows throughout the United States, affecting particularly calcareous hills and sunny exposures, and flowering in August. The root, which is the part used, is bitter and nauseous, and yields its active properties to boiling water.

Medical Properties and Uses. When recent it is said to act violently as a cathartic, and sometimes as an emetic. In the dried state it is more uncertain. The dose of the powder is from twenty grains to a drachm. It is one of the medicines which will probably be omitted on a future revision of the Pharmacopœia.

W.

◆

VINUM. *U.S.*

Wine.

"Vinum album Teneriffe dictum. *The white wine called Teneriffe.*" *U.S.*

Off. Syn. VINUM ALBUM HISPANUM. Anglicè, *Sherry, Ed.;* VINUM ALBUM HISPANUM. *Dub.*

Vin, *Fr.;* Wein, *Germ.;* Vino, *Ital., Span.*

Wine is the fermented juice of the grape, the fruit of the Vitis vinifera of botanists, an important plant, the description of which will be found under another head. (See *Uva Passa.*) The juice of sweet grapes consists of a considerable quantity of sugar, a peculiar matter of the nature of ferment or yeast, and a small portion of mucilage, tannin, supertartrate of potassa, tartrate of lime, common salt, and sulphate of potassa; the whole dissolved or suspended in a large quantity of water. Sour grapes contain, in addition, a peculiar acid isomeric with the tartaric, called *paratartaric acid.* Grape juice, therefore, embraces all the ingredients essential to the production of the vinous fermentation, and requires only the influence of the atmosphere and a proper temperature to convert it into wine. The theory of the vinous fermentation, and the agency of sugar in the process, have been explained under *Alcohol.*

Preparation. Though the art of making wine varies in different countries, it is, nevertheless, regulated by general rules which require to be observed. When the grapes are ripe, they are gathered, and trodden under foot in wooden vessels with perforated bottoms, through which the juice, called the *must*, runs into a vat placed beneath. The temperature of the air being about 60°, the fermentation gradually takes place in the must, and becomes fully established after a longer or shorter period. In the mean time, the must becomes sensibly hotter, and emits a large quantity of carbonic acid, which, creating a kind of effervescence, causes the more solid parts to be thrown to the surface in a mass of froth having a hemispherical shape called the *head.*

The liquor, from being sweet, becomes vinous, and assumes a deep red colour if the product of red grapes. After a while the fermentation slackens, and it becomes necessary to accelerate it by thoroughly mixing the contents of the vat. When the liquor has acquired a strong vinous taste, and become perfectly clear, the wine is considered as made, and is racked off into casks. But even at this stage of the process, the fermentation is not completed, but continues for several months longer. During the whole of this period, a frothy matter is formed, which, for the first few days, collects round the bung, but afterwards precipitates along with colouring matter and tartar, forming a deposite which constitutes the wine-lees.

Division and Nomenclature. Wines, according to their colour, are divided into the red and white; and, according to their taste and other qualities, are either spirituous, sweet, dry, light, sparkling, still, rough, or acidulous. *Red wines* are derived from the must of black grapes, fermented with their husks; *white wines*, from white grapes, or from the juice of black grapes fermented apart from their skins. The other qualities of wines above enumerated, depend on the relative proportions of the constituents of the must, and on the mode in which the fermentation is conducted. The essential ingredients of the must as a fermentable liquid, are water, sugar, and a ferment. If the juice be very saccharine, and contain sufficient ferment to sustain the fermentation, the conversion of the sugar into alcohol will proceed until checked by the production of a certain amount of the latter, and there will be formed a *spirituous* or *generous* wine. If, while the juice is highly saccharine, the ferment be deficient in quantity, the production of alcohol will be less and the redundancy of sugar proportionably greater, and a *sweet wine* will be formed. When the sugar and ferment are in considerable amount, and in the proper relative proportions for mutual decomposition, the wine will be strong-bodied and sound, without any sweetness or acidity, and of the kind called *dry*. A small portion of sugar can give rise only to a small portion of alcohol, aud consequently the less saccharine grapes will generate a comparatively weak, or *light wine*, which will be sound and stable in its constitution, in case the ferment is not in excess, but otherwise liable to pass into the acetous fermentation and become acescent. In case the fermentation is checked, and the wine bottled before it is fully completed, the process will continue slowly in the bottles, and the carbonic acid generated, not having vent, will impregnate the wine, and render it effervescing and *sparkling* when drawn. The *rough* or astringent wines owe their flavour to a portion of tannin derived from the husks of the grape; and the *acidulous* wines, to the presence of carbonic acid or an unusual proportion of tartar. Several of the above qualities are often combined. Thus a wine may be spirituous and sweet, spirituous and rough, rough and sweet, light and sparkling, &c.

Wines are made in many countries, and are known in commerce by various names according to their source. Thus, *Portugal* produces port and lisbon; *Spain*, sherry, saint lucar, malaga, and tent; *France*, champaigne, burgundy, hermitage, vin de grave, sauterne, and claret; *Germany*, white rhenish, hock, and moselle; *Hungary*, tokay, *Sicily*, marsala or Sicily madeira, and lissa; the *Cape of Good Hope*, constantia; *Madeira and the Canaries*, madeira and teneriffe. In the United States, a small portion of wine is made, for the most part of inferior quality. The best is manufactured near Vevay, a Swiss settlement on the banks of the Ohio. The consumption of this country is accordingly supplied almost entrely from abroad; and the wines most extensively imported are madeira and teneriffe, sherry and port, and the claret wines of France.

Properties. Wine, considered as representing a class, may be characterized as a spirituous liquid, the result of the fermentation of grape-juice, and containing mucilage, aroma, and some other substances, which are either combined or intimately blended with the spirit. All its other qualities vary with the nature of each particular wine. It will not be necessary to describe all the wines which have been enumerated; but only such as are commonly used for medicinal purposes. Under this denomination may be included the officinal wines teneriffe and sherry, together with madeira, port, and claret.

Teneriffe, the officinal wine of the U.S. Pharmacopœia, is a white wine, of a slightly acid taste, and, when of good quality, of a fine aromatic flavour. It ranks among the stronger white wines, and contains between 19 and 20 per cent. by measure of alcohol of sp. gr. 0.825. It is made from the same grape as madeira, to which it bears a close resemblance.

Sherry is of a deep amber colour, and when good possesses a dry aromatic flavour and fragrancy, without any acidity. Its average strength is about the same as that of teneriffe. This is the officinal wine of the Edinburgh College, and is probably the "Spanish white wine" intended by the Dublin College. It is prepared in the vicinity of Xeres in Spain, and hence its English name, *sherry*. This wine is supposed to have been the *sack* of Shakspeare, so called from the word *sec* (dry), in allusion to its being a dry wine. Its dryness or freedom from acidity is said to arise from the use of lime in its manufacture.

Madeira is the strongest of the white wines in general use. Like teneriffe, it is a slightly acid wine, and when of proper age, and in good condition, has a nutty, rich, aromatic flavour. As it occurs in the market, however, it is of very variable quality, on account both of the less care taken in its manufacture than formerly, and of the adulterations and mixtures to which it is subjected after importation. Nevertheless, the madeira consumed in this country is generally much better than that used in England, its adulteration being practised to a less extent with us, and our climate being more favourable to the improvement of the wine.

Port is of a deep purple colour, and, in its new state, is a rough, strong, and slightly sweet wine. When kept a certain length of time in bottle, it deposites a considerable portion of its astringent matter, loses the greater part of its sweetness, acquires more flavour, and retains its strength. If too long kept, it deposites the whole of its astringent and colouring matter, and becomes deteriorated. Considerable quantities of brandy are almost always added to it, which causes its heating quality on the palate. It is the strongest of all the wines in common use.

Claret, called in France *vin de Bordeaux*, is also a red wine, and from its moderate strength is ranked as a light wine. It has a deep purple colour, and when good a delicate taste, in which the vinous flavour is blended with those of slight acidity and astringency. The most esteemed kinds are the Medoc clarets, called *Château Lafite*, *Château Margaux*, and *Château Latour*. Another celebrated variety is the *Château Haut Brion* of the Pays de Grave. Claret is the only French wine which is extensively consumed in the United States. It is made in large quantities in the country around Bordeaux, from which port it is shipped.

Adulterations. Wines are very frequently adulterated, and counterfeit mixtures are often palmed upon the public as genuine wine. Formerly the wine dealers were in the habit of putting litharge into wines that had become acescent. The oxide of lead formed with the acetic acid acetate of lead, which, being sweet, corrected the defect of the wine, but at the same time rendered it poisonous. At the present day, however, this criminal practice is wholly abandoned, on account of the facility with which the adulteration is detected by chemical reagents, particularly by sulphuretted hydrogen, which causes a black and flocculent precipitate. Mr. Brande assures us, that among the numerous samples of wine of suspected purity which he had examined, he had not found one containing any poisonous ingredient fraudulently introduced. Lead, in minute quantity, according to this writer, may often be detected in wines; but it is derived invariably from shot in the bottle, or some analogous source. Spurious mixtures, frequently containing very little of the fermented juice of the grape, which are sold for particular wines, may not be poisonous; but are notwithstanding highly pernicious in their effects upon the stomach; and always produce mischief and disappointment, when depended on as medicinal agents. The wines most frequently imitated are port and madeira; and cider is generally the chief ingredient in the spurious mixtures. *English port* is sometimes made of a small portion of real port mixed with cider, juice of elder berries, and brandy, and coloured and rendered astringent with logwood and alum. In the United States, of latter years, the cheapness of genuine wines has left little motive for manufacturing these factitious imitations.

Composition. Wine, throughout all its varieties, has the same general composition. It consists of a large quantity of water, a variable portion of alcohol, a little mucilage, tannin, a blue and yellow colouring matter, acetic acid, supertartrate of potassa (tartar), tartrate of lime, and occasionally other salts, such as common salt and sulphate of potassa. There is also present in wine a peculiar aroma, which is supposed by some to depend upon the presence of an oil, but which has never been isolated. The different kinds of wine derive their various flavours and qualities from this aroma, as well as from the mode of fermentation, the nature of the grape, and the soil and climate in which it may have grown. The alcohol in pure wine is that which results from the vinous fermentation, and is intimately united with the other ingredients of the liquor; but with almost all the wines of commerce a certain portion of brandy has been mixed, the state of union of which is different from that of the natural alcohol of the wine. This seems to be proved by the experiments of Fabroni, who found, upon adding a large portion of carbonate of potassa to wine containing extraneous brandy, that the latter was thrown up to the surface in the form of a stratum; whereas from a pure wine, a similar treatment had no effect in separating the natural alcohol which it contained.

The intoxicating ingredient in all wines is the alcohol which they contain; and hence their relative strength depends upon the quantity of this substance entering into their composition. The alcohol, however, naturally in wine, is so blended with its other constituents, as to be in a modified state, which renders it less intoxicating and less deleterious than the same quantity of alcohol separated by distillation and diluted with water. Mr. Brande has published a very interesting table, giving the percentage by measure of alcohol of sp. gr. 0.825 in different kinds of wine. The following abstract contains his principal results.

	Alcohol per cent.		*Alcohol per cent.*
Lissa, average	25.41	Port	25.83
Raisin wine, average	25.12	Ditto	24.29
Marsala, [Sicily madeira], average	25.09	Ditto	23.71
		Ditto	23.39

	Alcohol per cent.		*Alcohol per cent.*
Port	22.30	Vidonia	19.25
Ditto	21.40	Alba flora	17.26
Ditto	19.00	Malaga	17.26
Average	22.96	White hermitage	17.43
Madeira	24.42	Rousillon, average	18.13

Cape madeira, average	20.51	Frontignac,	12.79
Grape wine	18.11	Côte rotie	12.32
Calcavella, average	18.65	Tokay	9.88

Besides the grape, a number of other fruits yield a juice susceptible of the vinous fermentation. The infusion of malt, also, is capable of undergoing this process, and becomes converted into the different kinds of porter and ale. The product in all these cases, though not commonly called a wine, is nevertheless a vinous liquor, and may be classed among the wines properly so called. The following is a list of these vinous liquors, together with the percentage of alcohol which they contain, as ascertained by Mr. Brande.—Currant wine, 20.55; gooseberry wine, 11.84; orange wine, 11.26; elder wine, 8.79; cider, from 5.21 to 9.87; perry, 7.26; mead, 7.32; Burton ale, 8.88; Edinburgh ale, 6.20; brown stout, 6.80; London porter, 4.20; small beer, 1.28.

Medical Properties and Uses. Wine is consumed in most civilized countries as an article of frequent beverage; but in a state of health it is at least useless, if not absolutely pernicious. The degree of mischief which it produces, depends very much on the character of the wine. Thus the light wines of France are comparatively innocuous; while the habitual use of the stronger ones, such as port, madeira, sherry, &c., even though taken in moderation, is always injurious, as having a tendency to induce gout and apoplexy, and other diseases dependent on plethora and over-stimulation. All wines, however, when used habitually in excess, are productive of the worst consequences. They weaken the stomach, produce diseases of the liver, and give rise to dropsy, gout, apoplexy, tremors, and not unfrequently mania. Nevertheless, wine is an important medicine, productive of the best effects in certain diseases and states of the system. As an article of the materia medica, it ranks as a stimulant and antispasmodic. In the convalescence from protracted fever, and in sinking of the vital powers, it is frequently the best remedy that can be employed. In certain stages of typhoid fevers, and in extensive ulceration and gangrene, this remedy, either alone, or conjoined with bark or opium, is often our main dependence. In low febrile affections, if it increase the fulness and lessen the frequency of the pulse, mitigate delirium, and produce a tendency to sleep, its further use may be deemed proper; but on the contrary, if it render the pulse quicker, augment the heat and thirst, produce restlessness, or increase delirium, it should be immediately laid aside as injurious. In some convulsive diseases, as for example tetanus, wine, liberally given, has been found useful.

Wine, when used medicinally, ought always to be sound, and good of its kind; for otherwise it will disagree with the stomach, and prove rather detrimental than useful. The individual wine selected for internal exhibition must be determined by the nature of the disease, and the particular object in view. *Teneriffe* is a good variety of white wine for medicinal use, being of about a medium strength, and agreeing very well with most stomachs. *Sherry*, when in good condition, is also a fine wine, and, being free from all acid, is to be preferred whenever the stomach is delicate, or has a tendency to dyspeptic acidity. Unfortunately, however, it is of very unequal quality. Good *madeira* is the most generous of the white wines, particularly adapted to the purpose of resuscitating debilitated constitutions, and of sustaining the sinking energies of the system in old age. The slight acidity, however, of pure madeira, causes it to disagree with certain stomachs, and renders it an improper wine for gouty persons. *Port* is generally used in cases of pure debility, especially when attended with a loose state of the bowels unaccompanied by inflammation. In such cases, it often acts as a powerful tonic as well as stimulant, giving increased activity to all the functions, especially digestion. *Claret* is much less heating, and is often useful on account of its aperient and diuretic qualities.

All the acid and acidulous wines are contra-indicated in the gouty and uric acid diatheses, as they are very apt to convert the existing predisposition into disease. They are useful, however, in what is called the phosphatic diathesis, their acidity tending to prevent the deposition of the earthy phosphates.

The quantity of wine which may be given with advantage in disease, is necessarily very variable. In low fevers, it may be administered to the extent of a bottle or more in twenty-four hours, either pure, or in the form of *wine-whey*. This is made by adding from a gill to half a pint of wine to a pint of boiling milk, straining without pressure to separate the curd which is formed, and sweetening the clear whey with loaf sugar. Wine-whey forms a peculiarly safe and grateful stimulus in typhoid fevers and other febrile affections, which, after depletion, may tend to a state of deficient action and be accompanied with a dry skin. Under these circumstances, it often acts as a diaphoretic, and, if used of moderate strength, without stimulating the system in any marked degree.

Pharmaceutical Uses. Wine is employed as a menstruum to extract the virtues of several plants, and the preparations thus formed are called *vinous tinctures* or *medicated wines.* Tartar emetic and iron are the only mineral substances prepared in a similar manner. (See *Vinum Antimonii* and *Vinum Ferri.*) The London College has superseded the use of wine altogether as a pharmaceutical agent, on account of its variable quality, and substituted spirit of equivalent strength. It is on this account that wine has latterly been expunged from their officinal list. Nevertheless, they have a class of preparations called "Vina," which name, by a solecism in language, is applied to medicines prepared with proof spirit and water, without the use of a particle of wine. For the peculiar powers of wine as a menstruum for medicinal substances, see *Vina Medicata.* B.

VIOLA. *U.S. Secondary.*

Violet.

"Viola pedata. Planta. *The Plant.*" *U.S.*

VIOLÆ ODORATÆ FLORES. *Ed.*

Flowers of the Sweet Violet.

Off. Syn. VIOLA ODORATA. Flores. *Dub.*

Violette odorante, *Fr.;* Wohlriechendes Veilchen, *Germ.;* Violetta, *Ital.;* Violeta, *Span.*

VIOLA. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Violaceæ.

Gen. Ch. Calyx five-leaved. *Corolla* five-petaled, irregular, horned at the back. *Anthers* cohering. *Capsule* superior, three-valved, one-celled.

This genus includes numerous species, of which, though perhaps all or nearly all are possessed of analogous properties, two only are recognised as officinal, the *V. odorata,* by the Edinburgh and Dublin Colleges, and the *V. pedata,* by our National Pharmacopœia. The *V. ovata,* an indigenous species, has been recommended as a remedy for the bite of the rattlesnake. (See a paper by Dr. Williams in the *Am. Journ. of the Med. Scien.* xiii. 310.)

Viola odorata. Willd. *Sp. Plant,* i. 1163; Woodv. *Med. Bot,* p. 251. t. 89. This is a small, pretty, creeping plant, the runners of which are furnished with fibrous roots, and send up annually tufts of leaves and flowers. The leaves are heart-shaped, crenate, and supported on long petioles. The flowers are at the summit of delicate, quadrangular, channeled, radical peduncles. The leaves of the calyx are shorter than the petals, which are obovate, obtuse, unequal, and of a bluish-purple or deep violet colour, except at the claws which are whitish. The two lateral petals are spreading and bearded towards the base, the inferior furnished with a large spur, and the two upper reflected. In the centre are the stamens with very short filaments, and anthers slightly cohering by an orange-coloured membranous expansion.

The sweet violet is a native of Europe, growing in woods, hedges, and other shady places. It is cultivated in gardens both for its beauty and for medical use; and has been introduced into this country. It is valued chiefly for its flowers, which appear in April and May.

The flowers of this species of violet, besides their beautiful colour, have a peculiar agreeable odour, and a very slightly bitter taste. These properties they yield to boiling water; and their infusion affords a very delicate test for acids and alkalies, being reddened by the former, and rendered green by the latter. Their odour is destroyed by desiccation; and the degree to which they retain their fine colour, depends upon the care used in collecting and drying them. They should be gathered before being fully blown, deprived of their calyx, and rapidly dried, either in a heated room, or by exposing them to a current of very dry air. The flowers of other species are often mingled with them, and, if of the same colour, are equally useful as a chemical test.

In the roots, leaves, flowers, and seeds of the *V. odorata*, M. Boulay has discovered a peculiar alkaline principle, bearing some resemblance to *emetia*, but possessing distinct properties. He calls it *violine;* but *violia* is its proper title in accordance with the nomenclature adopted in this work. It is white, soluble in alcohol, scarcely soluble in water, and forms salts with the acids. It exists in the plant combined with malic acid, and may be obtained by treating with distilled water the alcoholic extract of the dried root, decomposing by means of magnesia the malate of violia contained in the solution, and extracting the alkali from the precipitated matters by alcohol, which yields it on evaporation. To obtain it entirely pure, a more complicated process is necessary. Orfila has ascertained that it is exceedingly active and even poisonous. It is probably contained in most other species of Viola.

Viola pedata. Willd. *Sp. Plant.* i. 1160. Curtis, *Bot. Mag.* 89. This is an indigenous species, without stems, glabrous, with many-parted often pedate leaves, the segments of which are linear lanceolate, obtuse, and nearly entire. The flowers are large and of a beautiful blue colour. The divisions of the calyx are linear and acute. The stigma is large, compressed at the sides, obliquely truncate and perforate at the apex. The plant grows in dry sandy hills and fields, and rocky woods, from New England to Carolina; and flowers in May and June.

Medical Properties &c. of the Violets. The herbaceous parts of different species of violet are mucilaginous, emollient, and slightly laxative; and have been used in pectoral, nephritic, and cutaneous affections. Much was formerly thought of the *Viola tricolor* or pansy, as a remedy in the crusta lactea. A decoction in milk of a handful of the fresh, or half a drachm of the dried herb was taken morning and evening, and a poultice made with the same decoction was applied to the affected part. Cures in numerous instances are said to have been effected by this treatment persevered in for some time. Our own *Viola pedata* is considered a useful expectorant and demulcent in pectoral complaints. (*Bigelow.*)

In Europe, a syrup prepared from the fresh flowers of the *Viola odorata* is much employed as an addition to demulcent drinks, and as a laxative for infants. (See *Syrupus Violæ.*) The seeds were formerly considered useful in gravel; but are not now employed. The root, which has a bitter nauseous, slightly acrid taste, acts in the dose of thirty grains or a drachm as an emetic and cathartic. It is probable that the same property is possessed by the roots of all the violets, as it is known to be by several species of Ionidium, which belong to the same natural family. The existence in small proportion of the emetic principle, upon which the powers of the root probably depend, in the leaves and flowers, accounts for the expectorant properties long attributed to these parts of the plant. W.

WINTERA. *U.S. Secondary.*

Winter's Bark.

"Drymis Winteri. *De Candolle.* Wintera aromatica. *Willd.* Cortex. *The bark.*" *U. S.*

Off. Syn. WINTERÆ AROMATICÆ CORTEX. *Ed.;* WINTERA AROMATICA. DRYMIS AROMATICA. Cortex. *Dub.*

Ecorce de Winter, *Fr.;* Wintersche Rinde, *Germ.;* Corteccia Vinterana, *Ital.;* Corteza Winterana, *Span.*

Drymis. *Sex. Syst.* Polyandria Tetragynia.—*Nat. Ord.* Magnoliaceæ, *Juss.;* Wintereæ, *R. Brown, Lindley.*

Gen. Ch. *Calyx* with two or three deep divisions. *Corolla* with two or three petals, sometimes more numerous. *Stamens* with the filaments thickened at the summit, and anthers having two separated cells. *Ovaries* from four to eight, changing into the same number of small, many-seeded berries. *A. Richard.*

Drymis Winteri. De Cand. *Prod.* ii. 78; Foster, *Gen.* p. 84. t. 42.—*Wintera aromatica.* Willd. *Sp. Plant.* ii. 1239; Woodv. *Med. Bot.* p. 647. t. 226. This is an evergreen tree, varying very much in size, sometimes rising forty or fifty feet in height, sometimes not more than six or eight feet. The bark of the trunk is gray, that of the branches green and smooth. Its leaves are alternate, petiolate, oblong, obtuse, somewhat coriaceous, entirely smooth, green on their upper surface, of a pale bluish colour beneath, with two caducous stipules at their base. The flowers are small, sometimes solitary, but more frequently in clusters of three or four, upon the summit of a common peduncle about an inch in length, simple, or divided into as many pedicels as there are flowers. The tree is a native of the southern part of South America, growing along the Straits of Magellan, and extending as far north as Chili. According to Martius it is found also in Brazil. The bark of the tree was brought to England, in the latter part of the sixteenth century, by Captain Winter, who attended Drake in his voyage round the world, and while in the Straits had learned its aromatic and medicinal properties. Since that period it has been occasionally employed in medicine.

It is in quilled pieces, usually a foot in length, and an inch or more in diameter, appearing as if scraped or rubbed on the outside, where the colour is pale yellowish or reddish-gray, with red elliptical spots. On the inside the colour is that of cinnamon, though sometimes blackish. The pieces are sometimes flat and very large. The bark is two or three lines in thickness, hard and compact, and when broken exhibits on the exterior part of the fracture a grayish colour, which insensibly passes into reddish or yellowish towards the interior. The powder resembles in colour that of Peruvian bark. The odour is aromatic, the taste spicy, pungent, and even burning.

Winter's bark was found by M. Henry to contain resin, volatile oil, colouring matter, tannin, several salts of potassa, malate of lime, and oxide of iron. The presence of tannin and oxide of iron serves to distinguish it essentially from the *canella alba*, with which it is often confounded.

Medical Properties and Uses. It is a stimulant aromatic tonic, and was employed by Winter as a remedy for the scurvy. It may be used for similar purposes with cinnamon or canella alba, but is scarcely known in the medical practice of this country. The dose of the powder is about half a drachm. W.

◆

XANTHORHIZA. *U. S. Secondary.*

Yellow-root.

"Xanthorhiza apiifolia. Radix. *The root.*" *U.S.*

Xanthorhiza. *Sex. Syst.* Pentandria Polygynia.—*Nat. Ord.* Ranunculaceæ.

Gen. Ch. *Calyx* none. *Petals* five. *Nectaries* five, pedicelled. *Capsules* five to eight, one-seeded, semibivalve. *Nuttall.*

Xanthorhiza apiifolia. Willd. *Sp. Plant.* i. 1568; Barton, *Med. Bot.* ii. 203.—*X. tinctoria.* Woodhouse, *N. Y. Med. Repos.* vol. v. This is an indigenous shrub, two or three feet in height, with a horizontal root, which sends off numerous suckers. The stem is simple, rather thicker than a goose-quill, with a smooth bark, and bright yellow wood. The leaves, which stand thickly at the upper part of the stem, are compound, consisting of several ovate lanceolate, acute, doubly serrate leaflets, sessile upon a long petiole, which embraces the stem at its base. The flowers are small, purple, and disposed in long, drooping, divided racemes, placed immediately below the first leaves. The nectaries are obovate and bilobed, the styles usually about six or eight in number.

The yellow-root grows in the interior of the Southern and in the Western States. Nuttall says that it is abundant on the banks of the Ohio. It flowers in April. The root is the part directed by the Pharmacopœia; but the bark of the stem possesses the same virtues.

The root is from three inches to a foot in length, about half an inch in thickness, of a yellow colour, and of a simple but extremely bitter taste. It imparts its colour and taste to water. The infusion is not affected by a solution of the sulphate of iron. By the late Professor Barton the bark of the root was considered more bitter than its ligneous portion.

Medical Properties and Uses. Xanthorhiza possesses properties closely analogous to those of columbo, quassia, and the other simple tonic bitters; and may be used for the same purposes, and in the same manner. Dr. Woodhouse employed it in the dose of two scruples, and found it to lie easily upon the stomach. W.

◆

XANTHOXYLUM. *U. S. Secondary.*

Prickly Ash.

"Xanthoxylum fraxineum. Cortex. *The bark.*" *U. S.*

XANTHOXYLUM. *Sex. Syst.* Diœcia Pentandria.—*Nat. Ord.* Terebintaceæ, *Juss.;* Xanthoxyleæ, *Nees and Martius, Lindley.*

Gen. Ch. MALE. *Calyx* five-parted. *Corolla* none. FEMALE. *Calyx* five-parted. *Corolla* none. *Pistils* five. *Capsules* five, one-seeded. *Willd.*

Xanthoxylum fraxineum. Willd. *Sp. Plant.* iv. 757; Bigelow, *Am. Med. Bot.* iii. 156. The prickly ash is a shrub from five to ten feet in height, with alternate branches, which are covered with strong, sharp, scattered prickles. The leaves are alternate and pinnate, consisting of four or five pairs of leaflets, and an odd terminal one, with a common footstalk, which is sometimes prickly on the back, and sometimes unarmed. The leaflets are nearly sessile, ovate, acute, slightly serrate, and somewhat downy on their under surface. The flowers, which are small and greenish, are disposed in sessile umbels near the origin of the young shoots. The plant is polygamous, some shrubs bearing both male and perfect flowers, others only female. The number of stamens is five, of the pistils three or four in the perfect flowers, about five in the pistillate. Each fruitful flower is followed by as many capsules as it had germs. These capsules are stipitate, oval, punctate, of a greenish-red colour, with two valves, and one oval blackish seed.

This species of Xanthoxylum is indigenous, growing in woods and in moist shady places, throughout the Northern, Middle, and Western States. The flowers appear in April and May, before the foliage. The leaves and capsules have an aromatic odour recalling that of the oil of lemons. The bark is the officinal portion.

This, as found in the shops, is in pieces more or less quilled, from one to two lines in thickness, of a whitish colour, internally somewhat shining, with an ash-coloured epidermis, which in some specimens is partially or wholly removed, and in those derived from the small branches is armed with strong prickles. The bark is very light, brittle, of a farinaceous fracture, nearly or quite inodorous, and of a taste which is at first sweetish and slightly aromatic, then bitterish, and ultimately acrid. The acrimony is imparted to boiling water and alcohol, which extract the virtues of the bark. Its constituents, according to Dr. Staples, besides fibrous substance, are volatile oil, a greenish fixed oil, resin, gum, colouring matter, and a peculiar crystallizable principle which he calls *xanthoxylin*, but of which the properties are not designated. (*Journ. of the Phil. Col. of Pharm.* i. 165.)

Dr. Bigelow informs us, that the *Aralia spinosa*, or angelica tree, which grows in the Southern States, is occasionally confounded with the *X. fraxineum*, in consequence, partly, of being sometimes called like the latter *prickly ash*. Its bark, however, in appearance and flavour, is entirely different from the xanthoxylum.

Medical Properties and Uses. Xanthoxylum is stimulant, producing when swallowed a sense of heat in the stomach, with more or less general arterial excitement, and a tendency to diaphoresis. It is thought to resemble mezereon and guaiac in its remedial action, and is given in the same complaints. As a remedy in chronic rheumatism, it enjoys considerable reputation in this country. The dose of the powder is from ten grains to half a drachm, to be repeated three or four times a day. A decoction prepared by boiling an ounce in three pints of water down to a quart, may be given in the quantity of a pint, in divided doses, during the twenty-four hours.

The powder has sometimes been employed as a topical irritant, and the bark is a popular remedy for toothach. W.

◆

ZINCUM. *U.S., Lond., Ed., Dub.*

Zinc.

Speltre; Zinc, *Fr.;* Zink, *Germ.;* Zinco, *Ital., Span.*

Zinc occurs native in two principal states; as a sulphuret, called *blende*, and as a carbonate or silicate, denominated *calamine*. It is found in various parts of the world, but most abundantly in England and Germany, from which latter country the United States are principally supplied. The metal is extracted generally from calamine. This is roasted and mixed with charcoal powder, and the mixture heated in iron cylinders placed horizontally over a furnace. When the reduction of the zinc commences, iron receivers are adapted to the opening of the cylinder to receive the volatilized metal as it condenses. The metal is then melted and run into moulds, and forms *speltre*, or the zinc of commerce. In this state it is not pure, as it contains iron, lead, arsenic, copper, and charcoal. To purify it from these substances, it must be subjected to a second distillation in a crucible, furnished with a tube passing through its bottom and open at both ends; its upper extremity reaching a little more than half way up the interior of the crucible, and its lower end terminating above a vessel of water. The impure zinc being placed in the crucible, the cover luted on, and the fire applied, the pure zinc is volatilized, and passing down the tube by a descending distillation, condenses in the water below.

Properties. Zinc has a bluish-white colour, a peculiar taste, and a perceptible smell when rubbed. Its texture is laminated and its fracture crystalline. Its malleability and ductility are not very great. When perfectly pure, it may be reduced to thin leaves at ordinary temperatures; but the zinc of commerce requires to be heated to about 300° to render it laminable, at which temperature it may be conveniently reduced to the form of sheets, when it is applicable to many important uses in the arts. The softness of zinc is peculiar, as is shown by the circumstance that it clogs the file when the attempt is made to reduce it to filings; and hence if it be desired to have it in the divided form, it is necessary to submit it to fusion, and to triturate it at the moment of solidification. Its sp. gr. is about 7.1, and its equivalent number 32.3. Subjected to heat, it fuses at 773°. (*Daniell.*) At full redness it boils, and in close vessels may be distilled over; but in open ones it takes fire, and burns with a dazzling white flame, giving off dense white fumes. It dissolves in most of the acids with disengagement of hydrogen, and precipitates all the metals either in the metallic state or in that of oxide. It forms but one well characterized oxide, and but one sulphuret. The oxide is officinal, both in its pure and impure state, and will be described under other heads. See *Zinci Oxidum, U. S.*, and *Oxidum Zinci Impurum, Ed.*

Zinc is extensively employed in the arts. It is the best metal that can be used, in conjunction with copper, for galvanic combinations. Combined with tin and mercury, it forms the amalgam for electrical machines. Its solution in dilute sulphuric acid furnishes the readiest method for obtaining hydrogen. With copper it forms the useful alloy called brass, and in the form of sheet zinc it is sometimes employed to cover the roofs of houses. It should never be used for culinary vessels, as it is soluble in the weakest acids.

Pharmaceutical Uses. Zinc is never used in medicine in the metallic state; but in combination, it forms a number of important medicinal preparations, a list of which, with the synonymes, is subjoined.

Zinc is employed medicinally,—

ZINCI CARBONAS. *U.S.*

Carbonate of Zinc.

Off. Syn. CALAMINA. *Lond.;* CARBONAS ZINCI IMPURUS. *Ed.;* ZINCI CARBONAS IMPURUM. CALAMINA. *Dub.*

Calamine; Lapis calaminaris, *Lat.;* Carbonate de zinc, Calamine, *Fr.;* Galmei, *Germ.;* Pietra calaminare, *Ital.;* Calamina, *Span.*

The term *calamine* is applied by mineralogists indiscriminately to two minerals, scarcely distinguishable by their external characters, the *carbonate* nd *silicate* of zinc. The term, however in the pharmaceutical sense, refers o the native *carbonate* only.

Properties, &c. Carbonate of zinc is found in various localities. It occurs n Carinthia, Hungary, and other parts of the continent of Europe, and is articularly abundant in England. It has been found also in the United States. It usually occurs in compact or earthy masses, or concretions, of a ull appearance, readily scratched by the knife, and breaking with an earthy racture; but sometimes it is found crystallized. Its colour is very variable; eing, in different specimens, grayish, grayish-yellow, reddish-yellow, and hen impure, brown, or brownish-yellow. Its sp. gr. varies from 3.4 to 4.4. efore the blow-pipe, it does not melt, but becomes yellow and sublimes. It s distinguished from the other variety of calamine (silicate) by dissolving in arm nitric acid without gelatinizing, and by not being rendered electric by eat. In composition, it is essentially a carbonate of zinc; this being associated with more or less of foreign impurities. The crystallized variety is nhydrous, and consists of one equiv. of carbonic acid 22.12, and one of oxide f zinc 40.3=62.42. The compact and earthy varieties are said to contain ne equiv. of water.

Pharmaceutical Uses. Calamine is usually calcined before it is received n the shops, in order to render it more easily pulverizable. It requires to e brought to a state of impalpable powder before it can be used in medicine, nd in this state it forms the *Prepared Carbonate of Zinc*, under which head ts medical properties will be noticed.

* * *

OXIDUM ZINCI IMPURUM. *Ed.*

Impure Oxide of Zinc.

Tutty, Cadmia; Tutia, *Lat.;* Tuthie, Cadmie des fourneaux, *Fr.;* Tutia, *Germ.;* Tuzia, *al.;* Tucia, *Span.*

This oxide is officinal only in the Edinburgh Pharmacopœia. It is formed during the smelting of lead ores containing zinc. The oxide is deposited in the form of incrustations in the chimneys of the furnaces, from which it is detached and thrown into commerce.

Tutty is in the form of moderately hard and ponderous pieces, studded over with small protuberances, of a brownish colour on the outside, and yellowish within. Some pieces occasionally present a bluish cast, from the presence of small particles of metallic zinc. Sometimes a spurious article is sold for tutty, consisting of a mixture of blue clay and copper filings, made into a paste with water, and dried on an iron rod. It is distinguished from the genuine substance by its diffusing in water and exhaling an earthy smell, and by its greater friability.

Pharmaceutical Uses. Tutty is not used in medicine in the state here described, but requires to be levigated, when it becomes the *Oxidum Zinci Impurum Præparatum* of the Edinburgh College, under which head its medical properties will be mentioned.

ZINGIBER. *U.S.*

Ginger.

"Zingiber officinale. Radix. *The root.*" *U.S.*

Off. Syn. ZINGIBERIS RADIX. Zingiber officinale. Radix. *Lond.;* AMOMI ZINGIBERIS RADIX. *Ed.;* ZINGIBER. AMOMUM ZINGIBER. Radix. *Dub.*

Gingembre, *Fr.;* Ingwer, *Germ.;* Zenzero, *Ital.;* Gengibre, *Span.*

ZINGIBER. *Sex. Syst.* Monandria Monogynia.—*Nat. Ord.* Scitamineæ.

Gen. Ch. Flowers spathaceous. Inner limb of the *corolla* with one lip. *Anther* double, with a simple recurved horn at the end. *Germen* inferior. *Style* enclosed in the furrow formed by the anther. *Loudon's Encyc. of Plants.*

This genus was separated by Mr. Roscoe from the *Amomum*, and is recognised by the United States and London Pharmacopœias; though the Edinburgh and Dublin Colleges adhere to the former arrangement, and still denominate the plant which yields ginger, *Amomum Zingiber.*

Zingiber officinale. Roscoe, *Trans. Linn. Soc.* viii. 348; *Amomum Zingiber.* Willd. *Sp. Plant.* i. 6; Woodv. *Med. Bot.* p. 731. t. 250. The ginger plant has a perennial, creeping, tuberous root, and an annual stem, which rises two or three feet in height, is solid, round, erect, and enclosed in an imbricated membranous sheathing. The leaves are lanceolate, acute, smooth, five or six inches long by about an inch in breadth, and stand alternately on the sheaths of the stem. The scape or flower stalk rises by the side of the stem from six inches to a foot high, like it is clothed with oval acuminate sheaths, but is without leaves, and terminates in an oval, obtuse, bracteal, imbricated spike. The flowers are of a dingy yellow colour, and appear two or three at a time between the bracteal scales.

The plant is a native of Hindostan, and is cultivated in all parts of India. It is also cultivated in the West Indies, whither it was transplanted from the East. The flowers have an aromatic smell, and the stems, when bruised, are slightly fragrant; but the root is the portion in which the virtues of the plant reside. This is fit to be dug up when a year old. In the West Indies, the ginger crop is gathered in January and February after the stems have withered. After having been properly cleansed, the root is scalded in boiling water, in order to prevent germination, and is then rapidly dried. Thus prepared, it constitutes the ordinary ginger of commerce, or *black ginger*, as it is sometimes called, from the darkish colour which it acquires in the process. It is imported into this country almost exclusively from Calcutta, and is known to the druggists by the name of East India ginger. In Jamaica another variety is prepared by selecting the best roots, depriving them of their epidermis, and drying them separately and carefully in the sun. This is called in the books *white ginger*, and is most highly valued. It reaches us from England, where it is said to undergo some further preparation, by which its appearance is improved. It is usually called in our markets *Jamaica ginger*. The root is also brought immediately from the West Indies in a recent state and sold by the confectioners. A preserve is made from ginger by selecting the roots while young and tender, depriving them of their cortical covering, and boiling them in syrup. This is occasionally imported from the East and West Indies. When good it is translucent and tender.

The *recent root* is an inch or more in length, somewhat flattened on its upper and under surface, knotty, obtusely and irregularly branched or lobed, externally of a light ash colour, and marked with circular rugæ, internally fleshy, and yellowish-white. It sometimes germinates when kept in the shops.

The *common*, *East India*, or *black ginger*, is of the same general shape, but has a dark ash-coloured wrinkled epidermis, which being removed in some places, exhibits patches of an almost black colour, apparently the result of exposure. Beneath the epidermis is a brownish, resinous, almost horny cortical portion. The interior parenchyma is whitish and somewhat farinaceous. The powder is of a light yellowish-brown colour. This variety is most extensively used throughout the country.

The *Jamaica* or *white ginger* differs in being entirely deprived of epidermis, and white or yellowish-white on the outside. The pieces are rounder, and thinner, in consequence of the loss of substance in their preparation. They afford when pulverized a beautiful yellowish-white powder, which is brought from Liverpool in jars. This variety is firm and resinous, and has more of the sensible qualities of ginger than the black.

General Properties. The odour of ginger is aromatic and penetrating, the taste spicy, pungent, hot, and biting. These properties gradually diminish, and ultimately disappear when the root is long exposed. The virtues of ginger are extracted by water and alcohol. Its constituents, according to M. Morin, are volatile oil of a greenish-blue colour; a resinous matter, soft, acrid, aromatic, and soluble in ether and alcohol; a sub-resin insoluble in ether; a little osmazome; gum; starch; a vegeto-animal matter; sulphur; acetic acid; acetate of potassa; and lignin. The peculiar flavour of the root appears to depend on the essential oil, its pungency partly on the resinous or resino-extractive principle. A considerable quantity of very pure white starch may be obtained from it.

Those pieces of ginger which are very fibrous, light and friable, or worm-eaten, should be rejected.

Medical Properties and Uses. Ginger is a grateful stimulant and carminative, and is often given in dyspepsia, flatulent colic, and the feeble state of the alimentary canal attendant upon atonic gout. It is an excellent addition to bitter infusions and tonic powders, imparting to them an agreeable, warming, and cordial operation upon the stomach. When chewed it produces much irritation of the mouth, and a copious flow of saliva; and when snuffed up the nostrils, in the state of powder, excites violent sneezing. It is sometimes used as a local remedy in relaxation of the uvula, and paralysis of the tongue and fauces. Externally applied, it acts as a rubefacient. It may be given in powder or infusion. The dose of the former is from ten grains to a scruple or more. The infusion may be prepared by adding half an ounce of the powdered or bruised root to a pint of boiling water, and may be given in the dose of one or two fluidounces.

PART II.

PREPARATIONS.

THE preparation of medicines, which constitutes the art of Pharmacy, comes within the peculiar province of the apothecary. It is for his guidance that the various formulæ of the Pharmacopœia have been arranged, and to him that their directions are especially addressed.

A few general observations, therefore, of an explanatory nature, calculated to facilitate the progress of the pharmaceutic student, will not be misplaced under the present head. The business of the apothecary is to obtain a supply of good medicines, to preserve them with care, to prepare them properly for use, and to dispense them. Our remarks will embrace each of these points.

The substances obtained from the mineral and animal kingdoms, and those furnished by the chemical manufacturer, are of a nature to admit of no general precepts as to their proper condition, which would not be suggested by the common sense of the purchaser. He must receive them as offered, and judge of their fitness for his purposes by his knowledge of the peculiar properties of each. The same remark applies to vegetable substances from abroad; but with respect to indigenous plants, the apothecary is frequently called upon to exercise his judgment in relation to their collection and desiccation, and will derive advantage from some brief practical rules upon the subject.

Collecting and Drying of Plants. The proper mode of proceeding varies according to the nature of the part used. *Annual and biennial roots* are to be collected in the autumn, and *perennial roots* in the spring, before vegetation has commenced. They should be washed, and the small fibres, unless they are the part employed, should be separated from the fleshy solid part, which is to be cut in slices previously to being dried. *Bulbs* are to be gathered after the new bulb is perfected, and before it has begun to vegetate, which is at the time the leaves decay. *Barks*, whether of the root, trunk, or branches, should be gathered in the autumn or early in the spring. The dead epidermis, and the decayed parts, are to be separated. Of some trees, as the slippery elm, it is the inner bark only that is preserved. *Leaves* are to be gathered after their full development, before the fading of the flower. The leaves of biennial plants do not attain their perfect qualities until the second year. *Flowers* should in general be gathered at the time of their expansion, before or immediately after they have fully opened; and some, as the Rosa Gallica, while in the bud. *Aromatic herbs* are to be gathered when in flower. Leaves, flowers, and herbs, are to be gathered in clear dry weather, in the morning, after the dew is exhaled. *Stalks and twigs* are collected in autumn; *seeds* at the period of their full maturity.

Vegetables should be dried as rapidly as is consistent with their perfect preservation. *Fibrous roots* may be dried in the sun or in a room in which a heat of from 65° to 80° is maintained. *Fleshy roots* may be cut in transverse slices, dried in the open air till the moisture is nearly evaporated, and then placed in a stove heat not exceeding 100°, till perfectly dry and hard.

Bulbs must have the outer membranes peeled off, and be cut in transverse slices and dried in a heat not exceeding 100°. *Barks, woods*, and *twigs*, readily dry in thin layers in the open air. *Leaves* which are dry and thin do not require a heat exceeding 60° or 70°; those which are succulent may be exposed, by carefully and slowly raising the heat, to a temperature of 100°. *Flowers* must be dried carefully and rapidly in the shade; those of the most delicate texture and odour requiring the greatest care.

The following table, taken from the Edinburgh Dispensatory, presents the amount yielded by 1000 parts of the vegetables respectively mentioned, after being dried.

Roots of	Angelica Archangelica	263
	Aspidium Filix Mas	500
	Inula Helenium -	187
	Valeriana sylvestris	316
Bark of the	Oak - -	410
	Elder - -	292
	Elm - -	375
Twigs of	Solanum Dulcamara	308
Leaves of	Atropa Belladonna	140
	Conium maculatum	185
	Datura Stramonium	110
Leaves of	Digitalis purpurea	180
	Hyoscyamus niger	135
	Melissa officinalis	220
	Salvia officinalis	220
Tops of	Mentha piperita	215
Flowers of	Anthemis nobilis	338
	Borago officinalis	96
	Lavandula vera -	510
	Sambucus Ebulus	250
Petals of	Papaver Rhœas	84
	Rosa rubra -	330

Preservation of Medicines. The proper preservation of medicines is an art of the greatest importance to the apothecary. The aromatic gums and resins, and in general all the parts of vegetables, should be kept secluded from the light, and as much as possible from the air, in perfectly dry rooms. Boxes or barrels, with close covers, will serve for *roots* and *barks. Roots* which are to be preserved fresh should be buried in dry sand. *Leaves* and *flowers* should be kept in tin canisters, or boxes lined with lead or tin. They should be frequently examined, as they are liable to mouldiness, to the attacks of insects, and to a greater or less deterioration by age. The London College directs that vegetables should be collected annually, and that those which have been kept longer than a year should be thrown away.

Drugs frequently require to be garbled, as it is termed, before they are in a proper state for use. *Senna* is to be separated from the stalks and legumes; *lichen* from moss, leaves, and sticks; *myrrh* from bdellium, &c., *gum Senegal* from Bassora gum and a terebinthinate resin, *flaxseed* from clover seed; *seneka* from ginseng; *spigelia* from the stems, and both it and *serpentaria* from the adhering dirt. Seroons of cinchona should be examined, and the barks assorted before they are put by for use. *Gums* and *gum-resins* should be garbled, and the clear transparent tears preserved separately.

Weights and Measures. A precise acquaintance with the recognised measures of weight and capacity is essential to the operations of the apothecary. The weights used by him in compounding medicines, are the troy pound and its divisions; those by which he buys and sells, the pound avoirdupois and its divisions. The former contains 5760 grains, the latter 7000 grains, so that 11 troy pounds are nearly equivalent to 9 pounds avoirdupois. The troy pound contains 12 ounces of 480 grains; the avoirdupois pound 16 ounces of $437\frac{1}{2}$ grains, eleven of the former being nearly equal to twelve of the latter. The troy ounce is divided for the use of the apothecary, into 8 drachms of 60 grains each, and the drachm into 3 scruples of 20 grains each. The United States and British Pharmacopœias all recognise the troy weights, and whenever in this work any term is used expressive of weight, it is to be understood as being of this denomination.

The measures used by the apothecary are the wine pint and the gallon. The wine pint contains 28.875 cubic inches. The weight of a pint of distilled water at 62° Fahrenheit and 30° of the barometer, is 7289.7 grains, or 1 pound 3 ounces 1 drachm 29.7 grains troy, or 1 pound 289.7 grains avoirdupois. The gallon is divided into 8 pints, the pint into 16 fluidounces, the fluidounce into 8 fluidrachms, and the fluidrachm into 60 minims. The weight of a fluidounce of water is 455½ grains, being 18 grains more than an avoirdupois ounce. A drop is generally though incorrectly considered as equivalent to the minim. Drops vary in size according to the nature of the fluid, and the size and shape of the lip from which they fall. A drop of water nearly equals a minim. A fluidrachm of antimonial wine will make, on an average, about 72 drops, one of laudanum 120 drops, and one of alcohol 138 drops. For a table showing the relative value of minims and drops, see the Appendix.

Measures are employed by the United States, London, and Dublin Pharmacopœias, with a few exceptions, to express the quantity of liquids in all their formulæ. The Edinburgh College employs weights exclusively. This should be borne in mind in comparing the formulæ of the different Pharmacopœias.

Fluids are to be dispensed from graduated measures, of which those holding from a fluidounce to a pint are hollow inverted cones; and those holding a fluidrachm, and graduated to every five minims, are cylindrical. For smaller quantities than five minims, a slender tube holding a fluidrachm may be used, having the aliquot parts divided off and marked with a diamond. Care should be taken to verify these instruments. The following approximate measures are used in prescribing medicines, viz. a wineglassful containing two fluidounces, a tablespoonful containing half a fluidounce, a dessertspoonful two fluidrachms, and a teaspoonful containing a fluidrachm.

Specific Gravity. The specific gravity of fluids affords one of the best tests of their purity. The instrument commonly used by the apothecary for ascertaining this is Baumé's hydrometer. This is a glass bulb loaded at one end and drawn out at the other into a tube on which the scale is marked. That used for alcohol is graduated by loading it until it sinks to the foot of the stem (which is marked zero) in a solution of one part of salt in nine parts of water. It is then put into water, and the place to which it sinks marks 10° of the scale, which is constructed from these data. The hydrometer for liquids heavier than water is made by loading it, so that in distilled water it shall sink to nearly the top of the stem. The place to which it sinks in a solution of 15 parts of salt in 85 parts of water is then marked as 15°, and the scale divided off. For a table exhibiting the value of these scales in specific gravities, see the Appendix.

The hydrometers commonly imported are so carelessly made that scarcely any two will agree, and little dependence is to be placed on their accuracy. A more certain method consists in weighing the liquid at a uniform temperature in a bottle, the capacity of which, in grains of distilled water, has been previously ascertained. If a bottle is selected which will hold exactly 1000 grains of water at 60°, the weight in grains of the quantity of any liquid which it will hold will be the specific gravity of the liquid. Such bottles are sold in the shops. If one is not attainable, an ordinary vial may be used, and the specific gravity obtained by dividing the weight of the liquid examined by the weight of the water.

Gay Lussac's centesimal alcoholmeter is a very useful instrument, being graduated so as to indicate the percentage of absolute alcohol in any mixture of spirit and water.

The specific gravity of a solid is ascertained by first weighing it in air and then in water, and dividing the former weight by the difference between the two.

Mechanical Division. One of the simplest means of preparing medicines, is their reduction, by mechanical means, to a state of minute division. This includes the various operations of pulverization, levigation, grinding, filing, rasping, sifting, bruising, slicing, &c.

The principal drugs which are sold in the state of powder, are pulverized by persons who pursue that occupation for a livelihood. The apothecary, therefore, is chiefly interested in knowing the loss sustained in this process. The following statement has been abbreviated from a table prepared by MM. Henry and Guibourt. One thousand parts of the substances mentioned yielded, when pulverized—

Roots.				*Vegetable Products.*	
Jalap	940	Cinnamon	890	Aloes	960
Rhubarb	920	Angustura	825	Tragacanth	940
Columbo	900	*Leaves.*		Opium	930
Liquorice	900	Hemlock	800	Gum Arabic	925
Valerian	860	Savine	800	Scammony	915
Elecampane	850	Digitalis	790	Catechu	900
Gentian	850	Belladonna	785	Liquorice (extract)	810
Florentine Orris	850	Senna	720	*Animal Substances.*	
Rhatany	850	Henbane	530	Castor	900
Calamus	840	*Flowers.*		Spanish Flies	850
Virginia Snakeroot	800	Chamomile	850	*Mineral Substances.*	
Ipecacuanha	750	Saffron	800	Red Oxide of Mercury	980
Squill (bulb)	820	*Fruits.*		Red Sulphuret of Mercury	950
Barks.		Mustard	950		
Cinchona, pale	875	Black pepper	900	Arsenious Acid	950
————, red	880	Nux Vomica	850	Sulphuret of Antimony	950
————, yellow	900	Colocynth	500	Tin	825

For the greater part of those drugs that are powdered in the shops, an iron, brass, glass, or Wedgwood mortar is to be used; the two former for hard substances requiring repeated blows; the latter for those which are friable and can be reduced to powder by trituration. The interior surface of the mortar should be concave and nearly spherical, and care should be taken not to impede the operation by overloading and clogging the pestle. In powdering acrid substances, the mortar should be covered with a board perforated in the centre for the pestle, or with a large piece of pliable leather tied round the top of the mortar and the handle of the pestle, so as to allow of the free motion of the latter. The operator should guard himself against the fine particles of very acrid substances, by standing with his back to a current of air, and covering his nostrils with a wet cloth. Various means are used to facilitate the operation of powdering. All vegetable substances must be carefully and thoroughly dried. Resins, gum-resins, and gums, must be powdered in cold frosty weather. Tragacanth and nux vomica must be dried in a stove heat, and powdered while hot. The fibrous roots, as liquorice and marshmallow, should be previously shaved into thin transverse slices. Agaric is to be powdered by beating into a paste with water, then drying and triturating it. Cloves and the aromatic seeds may be ground in a hand mill and afterwards triturated. Squill and colocynth, the comminution of which is sometimes aided by soaking them in mucilage of tragacanth and then drying, are best powdered in a dry atmosphere, after being thoroughly dried in a stove heat. Camphor requires the addition of a few drops of alcohol. The efflorescent salts may be obtained in the state of fine powder by exsiccation, and those which are insoluble in alcohol, may be precipitated by it, in an impalpable powder, from their aqueous solutions.

Care should be taken in powdering, previously to separate the inert portions and impurities, and to mix intimately the whole of the powder which is reserved for use. The central woody fibre of ipecacuanha and other roots, the virtues of which reside in the bark, is to be rejected. The first portions of those barks to which lichens and the dead epidermis adhere, are inert, as are also the last particles of the fibrous roots and barks. The outer coat of the aromatic seeds is to be reserved, and the inner albuminous part rejected as inodorous.

The fine particles in powdering are to be separated from time to time by sifting. Fine sieves should be made of that sort of raw silk called bolting cloth; coarser ones of wire, hair cloth, or gauze. Valuable or aromatic powders should be passed through box sieves, which are sieves provided with covers for the top and bottom, that shut up so as to prevent all waste.

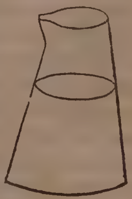
Ivory, horn, nux vomica, wood, and iron, are prepared for pharmaceutic purposes by filing or rasping; guaiacum wood by turning in a lathe; roots, stalks, and leaves by cutting with a large pair of shears, such as is used by the tinplate workers; or with a large knife fixed in a frame at one end, and furnished with a long handle at the other. Tin and zinc are granulated by melting them and strongly agitating whilst they are cooling; carbonate of potassa by stirring with a rod as it hardens.

Earthy insoluble substances are conveniently reduced to powder by *levigation.* This is performed by moistening them with alcohol or water, and rubbing them on a hard flat stone with a muller or rubber of the same material. The powder may be rendered impalpable by agitating it with a large quantity of water, and pouring off the liquid to settle, after the coarser particles have subsided. The fineness of the powder depends on its specific gravity and the length of time which elapses before the liquid from which it subsides is drawn off. This last operation is termed *elutriation*, and the thick pasty mass which remains, is usually dropped on an absorbent surface, and dried in the shape of small cones. Vanilla, mace, and other oily aromatic substances, may be rubbed to powder with sugar; magnesia and white lead, by friction on a wire or hair sieve.

Separation of Solids from Liquids. This is another mechanical operation which is frequently resorted to in practical pharmacy. It includes the processes of decantation, filtration, straining, expression, clarification, &c.

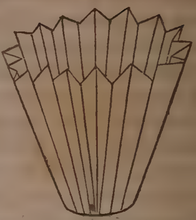
Solids may be separated from fluids when there exists no chemical action between them, by allowing them to subside. The supernatant liquid may then be carefully poured off; or it may be drawn off by a syphon; or separated by filtering. The last operation, or expression by a stronger force, is necessary to separate the whole of the liquid.

Precipitating jars of the shape figured in the margin, are sold in the shops, and will be found very useful.

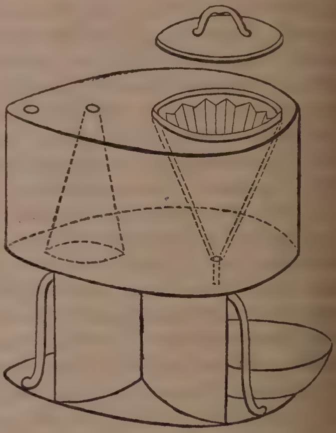


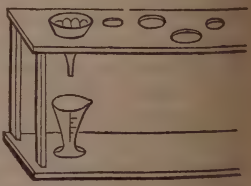
When the powder subsides slowly, or remains suspended, the liquid must be filtered.

The most convenient material for a filter is unsized paper. This is to be folded into a cone of the shape of the annexed figure, and placed in a glass funnel. It will serve for filtering tinctures, wines, saline solutions, watery infusions, and essential oils. In some cases it may be necessary to place a small cone of the same material outside of the large one, in order to



strengthen it. When the liquid is too viscid to pass readily through paper, a cotton or woollen bag of a conical shape may be used. Acids may be filtered through a layer of fine siliceous sand, supported in the neck of a glass funnel by pieces of glass gradually decreasing in size. Castor oil, syrups, and oxymels, may be readily filtered through coarse paper made entirely of woollen shreds. Melted fats, plasters, resins, and wax, may be *strained* through muslin stretched over a square frame or a hoop. Small sieves of fine bolting cloths serve for straining emulsions, decoctions, and infusions; and a temporary strainer for these purposes may be made by fastening a piece of muslin between the upper and lower parts of a common pill box, and then cutting off the ends so as to leave the rim only of the box around the muslin. The filtration of viscid substances is facilitated by heat. Filtration through bone black, is practised for muddy or dark coloured liquids. Much inconvenience is often experienced in the filtration of hot saturated saline solutions, by the cooling of the liquid and consequent crystallization of the salt in the filter and neck of the funnel. To obviate this, the tin apparatus represented in the wood cut, has been contrived by Professor Hare. The vessel is filled with hot water, which is kept at a boiling heat by a spirit lamp placed under the cavity having the shape of an inverted funnel. A glass funnel with a filter is placed in the other cavity, and the liquid passes through rapidly. In filtering alcoholic solutions, it is necessary to protect the liquid from the flame of the lamp, and for this purpose the partition underneath has been added. No apothecary should be without this useful apparatus. Frames of various sizes for holding funnels and filters will be found very useful; the wood cut represents the one commonly used. The efflorescence of saline solutions on the edge of the filtering paper may be prevented by dipping it in melted tallow or lard.





The filtration of liquids, which are altered by exposure to the air, requires much caution. A very simple method of accomplishing this, is to insert a slender tube of glass into the funnel, long enough to reach below the neck, while the upper part is nearly as high as the top of the funnel. The space between the tube and the neck, must be filled with bits of glass and fine sand, so as to form a good filtering bed; the liquid is to be poured in, and the top of the funnel covered with a plate of glass. If this be luted on, and the funnel luted into the neck of the bottle, the process will be performed with perfect accuracy.

Expression is required to separate the last portions of tinctures or infusions from the dregs.* A screw press is used for this purpose. The substance to be pressed is put into a cylinder of strong sheet tin, the sides of which are pierced with small holes. This is placed on a square tray of tin having a lip for pouring. A block of wood fits into the cylinder and is placed on the top, and the whole is put under the screw press, the pressure of which is gradually brought to bear upon it.

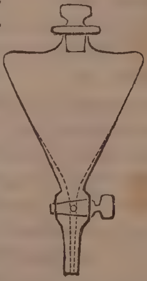
---

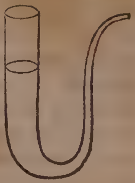
* The same object may be effected on the principle of *displacement*—a term applied to that operation by which any liquid impregnating a powder, may be expelled or displaced from it, to the last drop, by the addition of another fluid or a fresh portion of the same

This press is to be used for expressing the juices of fresh plants, and the mother liquor from precipitates or soft fibrous crystals. Previously to being pressed, plants must be well beaten in a mortar, and water added to those which are hard and dry.

The expressed oils are obtained by bruising the seeds which contain them, and enclosing the bruised mass in strong bags which are placed in a firm hollow frame and subjected to strong sudden pressure by driving up a wedge. Expressed oils are clarified from mucilage by boiling them with water.

Liquids in general are rendered clear by the addition of some coagulable substance, such as milk or an aqueous solution of ichthyocolla. The white of an egg beaten up with water, will coagulate by a gentle heat and clarify any liquid with which it has been mixed. The vegetable acids will clarify many of the expressed juices of plants.



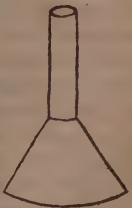


Separation of Liquids. Liquids which have no chemical affinity, and differ in specific gravity, may be separated by allowing them to remain at rest in the separating funnel represented in the annexed figure, and then drawing off the heavier fluid.

A very convenient method of separating fluids is by means of the separatory figured in the wood cut. The last drop of the heavier fluid may be drawn off by means of this instrument.

Application of Heat. The most efficient and economical means of obtaining heat is a subject of great importance to the pharmaceutist, on account of the variety of processes in which it is required.

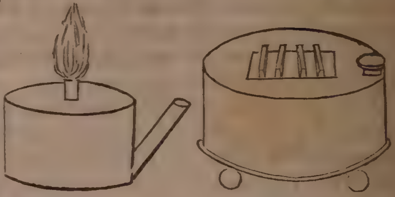
With the small furnaces, which are now made of fire clay, of various patterns and sizes, almost all the operations of the laboratory which require heat, can be performed. The fuel used is charcoal, although anthracite will burn in those of a larger size, and is to be preferred where a uniform heat is necessary for several hours. The apothecary should be provided with a complete set of these useful utensils including ne with a dome for a reverberatory furnace. By adding pipe several feet in length to this, and urging the fire with a air of double bellows, the heat may be raised to that of an air urnace. A small pipe of sheet iron with a cone at the lower nd, as in the figure, to fit on the furnace, will be found an xcellent means of obtaining an intense heat in those of the mallest size. For operations on a smaller scale, the most conenient means of obtaining heat is by an alcoholic lamp. Alohol burns without smoke or smell, and is almost as cheap a

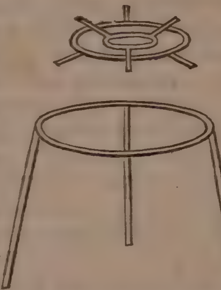


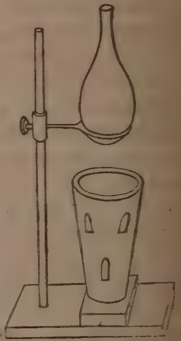
---

uid. All that is necessary is to pour the fluid upon the moist powder contained in the lter, in such a manner as to penetrate it equably. The added liquor thus drives before it at previously mixed with the powder, which may in this way be as completely exhaustas it can be by the press. In the preparation of tinctures or other medicated fluids tended for medical use, the displacing liquor should be the same with that employed as e menstruum; as the risk of contaminating the preparation with a foreign substance is us avoided.—W.

fuel as oil, to which it is on every other account preferable. The annexed figures represent the usual forms of spirit lamps. The larger one will be found very useful for heating spatulas for spreading plasters. For regulating the temperature and supporting the substance to be heated, iron tripods of various heights and sizes must be provided. These should be furnished with sets of concentric rings as in the figure, fitting into each other for vessels of different sizes. A very convenient support is the stand and ring figured in the wood cut, which will answer either for a spirit lamp, or a small furnace made from a black lead crucible as in the figure.



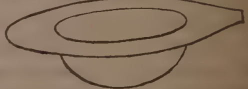


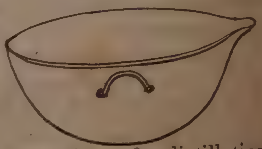


The operations which require the aid of heat are *fusion*, *solution*, and *evaporation*.

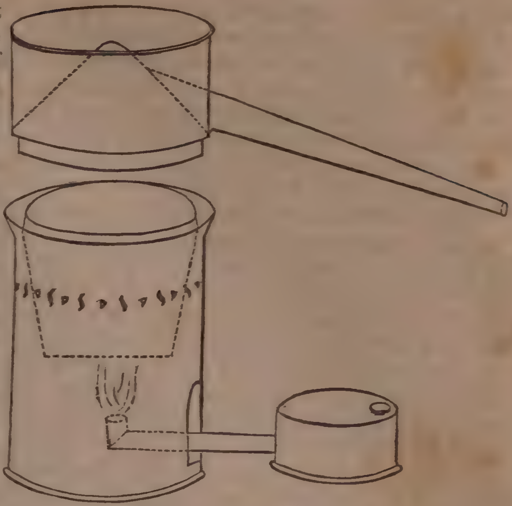
The temperature required for fusion, in pharmaceutical processes, seldom exceeds a red heat; and the vessels used are crucibles of silver, porcelain, Wedgwood ware, black lead, and fire clay (Hessian crucibles). Silver is used for the fusion of potassa, porcelain for nitrate of silver, and black lead and Hessian crucibles for the metals, glass of antimony, sulphuret of potassium, and the ordinary operations which require a great heat. They are each liable to objections; silver fuses too readily; porcelain and Wedgwood ware do not bear sudden changes of temperature; black lead, which bears these changes, is destroyed by saline substances and burns in a current of air; and the Hessian crucibles are so porous as to absorb and waste much of the fused substance. The crucibles should be covered with a lid or an inverted crucible, and should be supported at a little distance from the bottom of the grate, and surrounded and covered with ignited coals. The fusion of substances which soften and melt at a lower degree of heat, as wax, fat, plasters, &c., is called liquefaction. This operation is performed in open earthen, copper, or iron vessels, and care must be taken not to raise the heat so as to char or inflame the substance.

A *sand bath* is an indispensable part of the pharmaceutic apparatus. It is usually an iron pot or a shallow vessel of sheet iron capable of holding sand to the depth of four or six inches. It serves to regulate the action of the heat on vessels which do not bear a rapid change of temperature. It is sometimes heated to a red heat, as in preparing the mineral acids, though more frequently used for the evaporation of saline solutions and vegetable juices. The *water bath* is to be used in all cases in which a heat above that of boiling water would be injurious. A very convenient one, figured in the wood cut, consists of two copper vessels, the upper one of which is well tinned.



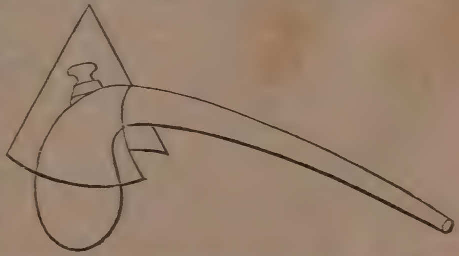


The common still and worm, the vessels in general use for distillation, are too well known to need description. A convenient still or alembic for



small operations, which may be heated by a spirit lamp, is figured in the wood cut. The top of the head is kept filled with cold water, and all escape of vapour is prevented by filling the space in which the head fits with water. The condensation of all the vapour is secured by adapting a worm or a long tube to the apparatus. The boiler of this still may hold one or two gallons, and it will be found a very useful means of recovering the alcohol in making alcoholic extracts. It may easily be converted into a water bath by fitting on the top of the boiler a vessel of convenient form.

For the extrication and condensation or absorption of gaseous fluids, a retort and series of three necked (or Wolfe's) bottles are used. The bottles are partly filled with water and become saturated in succession. As the tubes which convey the gas are plunged nearly to the bottom of the liquid in the bottles, there is danger, when the operation is complete, and a vacuum formed in the retort, of the water being driven by the atmospheric pressure in the last bottle, back through the whole series, so as to fill the retort. To prevent this, safety tubes must be fitted to the retort and the bottles. Those for the bottles are straight tubes, dipping a small depth into the liquid; that for the retort, is the common Welter's tube of safety. When the common glass retort and receiver are used for the distillation of fluids, care should be taken not to apply the luting until the atmospheric air is expelled. The chief objects to be aimed at are to keep the body of the retort hot and the neck and receiver cool. A hood of pasteboard or tin, as represented in the figure, will much facilitate the former, and the latter will be gained by keeping the neck and receiver wrapt in wet cloths, on which a jet of cold water is kept playing.



When the object of distillation is to preserve the residuum, and this is liable to injury from heat, as is the case with vegetable extracts, the operation is best performed in vacuo. For this purpose the still and recipient are made so as to form an air tight apparatus, and the latter is furnished with a stop cock, which is kept open until the whole of the atmospheric air is expelled by the vapour. It is then closed, and a vacuum formed and maintained in the recipient by surrounding it with cold water. The distillation is carried on in this manner at a much lower temperature than ordinary.

The vapours of some volatile solids have the property of condensing into the solid form, either in mass, or in a state of the most minute division. The operation in which this occurs, is called *sublimation.* When the product is compact, it is called a *sublimate*, when slightly adhering, it is called *flowers.* The operation is generally performed in a sand bath, and the apparatus consists of two vessels fitting each other, one being inverted over the other. The shape, size, and depth of the vessels, and the degree of heat to be applied, are regulated by the nature of the substance operated on.

Lutes. The most precious material for the chemists is glass, the transparency, insolubility, and hardness of which fit it for almost every purpose. It is often necessary to strengthen it by means of lutes, which will bear a heat at which glass would soften; and the application of lutes for this purpose, and for securing the junctures of tubes and vessels, is also an important part of the pharmaceutic art. Those lutes which are required for coating vessels exposed to a great heat, are made of Stourbridge clay. The clay is made into a paste with water mixed with chopped straw, and successive coats applied as they become dry. Earthenware vessels may be rendered impervious to air or vapours, by brushing over them a thin paste made of slaked lime and a solution of borax containing an ounce to the half pint. This is allowed to dry, and the vessel is then coated with slaked lime and linseed oil beaten till the mixture becomes plastic. Earthenware retorts thus coated, may be safely used more than once, the coating being renewed every time.

Fat lute is applied to the joinings of apparatus to prevent the escape of corrosive vapours. It is made like glazier's putty, pipe clay being substituted for whiting. It will bear a considerable heat, and great care must be taken that the part where it is applied be perfectly dry. If it is to be exposed to heat, slips of moistened bladder must be wrapped round it and secured with twine.

Roman cement and plaster of Paris may be applied in the same manner as fire clay; when used for securing the joinings of apparatus, a coating of oil or wax will render them air tight.

A very useful lute is formed by beating the white of an egg thoroughly with an equal quantity of water, and mixing with it some slaked lime in the state of fine powder, so as to form a thin paste. This must be spread immediately on slips of muslin and applied to the cracks or joinings intended to be luted. It soon hardens, adheres strongly, and will bear a heat approaching to redness without injury. A leak in this lute is readily stopped by the application of a fresh portion. Solution of glue, or any liquid albuminous matter, may be used in place of the white of eggs.

An excellent cement for surfaces of iron, consists of one part of sulphur, two of sal ammoniac, and eighty of iron filings, mixed together and slightly moistened. It is rammed or caulked into the joints, and solidifies perfectly in time.

White lead ground in oil, is an excellent cement for broken glass: spread upon linen, it forms a good coating for a cracked surface, but dries slowly.

Strips of bladder macerated in water, adhere well to glass, and are very useful.

A mixture of whiting and paste or gum water, spread upon strips of paper, forms an excellent luting for joinings not exposed to acrid vapours or a great heat.

A useful lute is formed by spreading a solution of glue on strips of cloth, and coating them, after they are applied, with drying oil.

Linseed meal beaten into a uniform mass with milk, lime-water, rye paste, or thin glue, and applied in thick masses, adheres well; and when dry, will resist most vapours.

Cap cement is made of six parts of resin, one part of yellow wax, and one of Venetian red. It is a very useful cement for fastening metals or wood to glass, and for rendering joints impervious to water. *Soft cement* is used for the same purposes, and is made of yellow wax melted with half its weight of turpentine, and coloured with a little Venetian red. It is very useful for rendering the stoppers of bottles perfectly air tight.

Chemical Operations. Some of the chemical processes conducted by the apothecary, have been explained in the former part of this introduction. It remains to notice some others in constant or frequent use. *Infusion* is the subjecting of a substance containing soluble principles to the action of a menstruum, which is usually water. Hot infusions are made by pouring boiling water on the substance, and allowing it to remain in a covered vessel till cold. Cold infusions are made with cold water, and require several hours to attain their full strength. *Maceration* is the term employed to denote the action of liquids upon medicines, when allowed to remain upon them for several days, at a heat of from 60° to 90°. *Digestion* is the name given to the same operation, when conducted at a temperature of between 90° and 100°. It is commonly performed in glass bottles or flasks, and a common fire or stove heat is employed. *Decoction*, or boiling, is sometimes employed in extracting the virtues of plants, but is often disadvantageous, as most of the proximate principles of vegetables are altered by it, especially when long continued. Where it is practised, the ebullition should generally be continued for a few minutes only, and the liquid be allowed to cool slowly in a close vessel.

From the solutions of vegetable principles obtained by these different processes, extracts are prepared by slow *evaporation*, so as to *inspissate* the liquid. This process should, as has already been mentioned, be always conducted at a heat not exceeding that of boiling water. Evaporation at a gentle heat is also performed for the *concentration* of saline solutions, in order to promote their *crystallization*. The proper degree of concentration is attained, if a drop of the liquid on a cold glass plate deposites crystals. The slower the evaporation and the cooling, and the greater the quantity operated on, the larger will be the crystals.

Water which is saturated with any salt is still capable of dissolving other salts. It is in this way, by washing crystals of impure salts with their own saturated solutions, that the crystals are purified. Fine silky crystals, which retain their mother water by capillary attraction, must be dried by strong expression in a linen bag. The finest silky crystals may be entirely freed from their adhering liquid by placing them in a funnel which fits closely to one of the necks of a double mouthed bottle, and fitting a tube to the other, through which air is drawn. The current of air, in passing through the funnel, carries the water with it, and dries the crystals perfectly.

Lixiviation is a process used for separating a *soluble* from a porous *insoluble* body. It consists in placing the substance to be lixiviated in a vessel, the bottom of which is covered with straw, &c., pouring water upon it, allowing the water to remain until saturated, and then drawing it off through an opening at the bottom of the vessel.

Precipitation is sometimes mechanical, as in the process of *levigating* and *elutriating* the carbonate of lime, and sometimes chemical, as in the preparation of this salt by decomposing the muriate of lime. When a precipitant is directed to be added until no further precipitation takes place, the fact may be ascertained by taking a drop of the liquid on a glass plate, and trying it with the precipitant. The formation of a precipitate is often much assisted by agitation or by heat. The separation of the supernatant liquid from the precipitate is most effectually accomplished by means of a syphon. When the liquid is a saline solution, it is necessary to wash the precipitate until the water exhibits no trace of the salt. In doing this, great care must be taken to select the purest and clearest water, and the ultimate drying of the precipitate must be performed in a filter, or on a porous stone.

The operations which require a heat greater than that used in digesting, are *liquefaction*, *fusion*, *calcination*, *ustulation*, *incineration*, *distillation*, and *sublimation*.

Liquefaction is the melting of those substances that become soft previously to fusion, as wax, tallow, plasters, &c. The heat employed is always below that at which charring takes place.

Fusion is employed in pharmacy in preparing the nitrate of silver and caustic potassa for casting into cylinders. The former must be melted in a porcelain, the latter in an iron crucible. The moulds in which they are cast are formed of two thick plates of cast iron, with semi-cylindrical grooves that fit accurately to each other. Fusion is also used in preparing the glass of antimony.

Calcination is a term applied to the changes produced in mineral substances by intense heat, not attended with fusion and leaving a solid residue, and is often synonymous with oxidation. The term *ustulation* is restricted to the metallurgic operations of roasting ores, to drive off the volatile matters, as arsenic, &c. Calcination is often used to express the ustulation or burning of carbonate of magnesia. This is to be performed in an earthen vessel at a red heat. Exposure to the hottest part of a potter's furnace during the burning of the kiln, is an excellent mode of performing the operation. More commonly, the magnesia is burnt in an iron pot, which is objectionable, as the heat soon oxidates the iron, and the oxide scales off and mixes with the magnesia, which is seldom free from iron when prepared in this way.

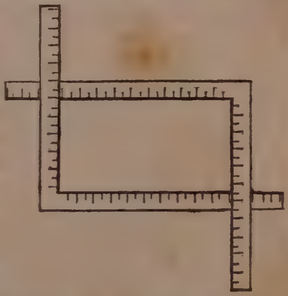
Incineration, as the name expresses, is the operation of burning substances for the sake of their ashes. It is performed in obtaining the phosphate of lime—the Cornu Ustum of the London Pharmacopœia. The bones are burnt in an open fire until all the inflammable matter is consumed.

Distillation and *sublimation* have already been spoken of. The former is used for separating a more volatile liquid, as ether or alcohol, from one less so; for impregnating a liquid with the volatile principles of plants, to the exclusion of other principles, as in the preparation of aromatic spirits and waters; and for separating, by means of aqueous vapour, the essential oils and volatile proximate principles of the vegetable kingdom. The first process is termed *rectification*. When the second process is repeated with the same liquid and a fresh quantity of the plant, the operation is termed *cohobation*. In submitting the solid parts of vegetables to distillation in the two latter processes, it will be found advisable to expose them to the action of vapour on a grate or in a basket, so as to preserve them from touching the bottom of the still, where they would be liable to be heated so as to become empyreumatic. Distillation is also used for obtaining the volatile products which result from the decomposition by heat of substances of animal or vegetable origin. The *oils* which are obtained in this manner are called *empyreumatic oils*. Sometimes the result is an acid, as the succinic acid, and sometimes the volatile alkali, as in the destructive distillation of animal substances.

Dispensing of Medicines. A large portion of the operations of the apothecary is performed in the shop extemporaneously. In dispensing medicines from the counter, he is continually called upon to put his previous knowledge in practice, and often to substitute extemporaneous for the regular officinal formulæ. There is no part of his business which requires for its proper performance so much ready judgment, and such accurate knowledge. A few directions, suggested by running the eye over the list of preparations of the Pharmacopœia may be found useful.

It may sometimes be necessary for the apothecary to make extemporaneously an aromatic water, which is not usually kept in the shops. In this case, he is to prepare it by rubbing a drop of essential oil with one or two grains of carbonate of magnesia, for every fluidounce of water, and filtering.

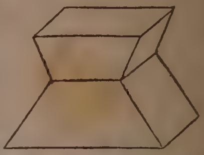
It is sometimes desirable to apply plasters prepared from the narcotic herbs. These may be made extemporaneously by mixing the soft extracts of the plant with about an equal weight of melted adhesive plaster, keeping the mixture soft, and stirring it until the moisture is evaporated. The most suitable material on which to spread plasters is soft white leather. A margin of half an inch should be allowed to remain around the plaster. The plaster iron or spatula may be heated in the large spirit lamp, figured in page 694. A skilful apothecary will be able to spread the plaster uniformly and evenly, without overheating it so as to penetrate or corrugate the leather. A convenient instrument for determining the size and preserving a straight edge, consists of two squares made of tin and graduated to inches, as in the annexed figure. For plasters of irregular shapes, pieces of paper may be cut out and pasted on the leather, so as to enclose a space of the required dimensions. The plaster should first be melted on a piece of brown paper, and then transferred to the leather, in order to prevent its being applied at too great a heat.



Decoctions and infusions are often ordered in prescriptions in the quantity of a few ounces. A very convenient vessel for preparing them in, is the common nursery lamp, which consists of a cylindrical vessel, open at the side for a spirit lamp, and at the top to receive a tea pot or tin boiler.

The neutral mixture is known to be saturated perfectly, when it does not affect litmus paper, either in its blue state or when reddened by acid. For preparing this and the effervescing draught, it is advisable to keep in the shop a solution of carbonate of potassa, containing an ounce to the pint. The silica which this salt contains, subsides on exposure, and leaves a perfectly clear solution, whereas that prepared at the time it is to be used, always becomes turbid after being saturated. The carbonic acid which is extricated on preparing the neutral mixture, combines at first without effervescence with the remaining carbonate and forms a bisalt. This circumstance may lead, unless the solution be tested, to the supposition that the mixture is saturated.

Powders are often mixed together with difficulty, by means of a pestle and mortar, on account of their differing greatly in weight, or of their softness and compressibility. In these cases, frequent stirring with a pallet knife becomes necessary to produce a perfect mixture. In dividing powders into doses, it is very desirable to fold the packages neatly and of a uniform size; the powder folder represented in the figure is very useful for this purpose. It may be made of mahogany or other hard wood.



It is important to the apothecary to ascertain the best means of combining substances which have no affinity for each other. This can often be done by means of a third substance. Water can be saturated with camphor by means of magnesia, and an aqueous mixture of any strength may be made with it, by triturating the camphor with magnesia and shaking the mixture before using it. Camphor softens the gum-resins and solid fats and oils, and may be rendered permanently soluble in water in considerable quantity, by trituration with a fifth part of myrrh. In preparing oily emulsions in which gum Arabic or gum and sugar are the medium, a sufficient quantity of water must be added to convert them into a thick mucilage before adding the oil, which must then be thoroughly mixed with it and the remaining water added gradually with great care. Sulphuric ether is rendered more soluble in water by trituration with spermaceti. The mixture should be filtered to separate the superfluous spermaceti. Mixtures that contain the resinous tinctures, should also contain syrup, with which the tinctures should first be mixed, and the water then added very gradually. If a mixture contains laudanum and a fixed oil, the former should be first mixed with the syrup, and the oil afterwards incorporated, and lastly the water; the mixture will not otherwise be uniform.

In ordering pills, care must be taken to avoid the use of deliquescent salts, and to deprive those which are used, of their water of crystallization. The mass must be thoroughly incorporated previously to being divided; and this is particularly important when extracts of different degrees of hardness enter into the composition. A section of the mass should be throughout of uniform colour and consistency. Pills are to be rolled and preserved in powdered liquorice root, which ought to be kept for use in a tin box with a perforated lid, like a pepper box. When pills are of too soft a consistence, a little liquorice powder may be incorporated with them to render them more firm. Pills into the composition of which gum Arabic enters, should be softened with syrup and not with water; as the latter renders the mass difficult to roll.

The proper cleanliness of his vessels is an object of great importance to the apothecary. Open vessels, as mortars and measures, are easily cleansed, and should be wiped dry immediately after being washed. Fats and resins are easily removed by pearlash, or tow and damp ashes, or sand. Red precipitate and other metallic substances, may be removed by a little nitric or muriatic acid. Bottles may be cleansed from most kinds of impurity, by well shaking them with shreds of coarse grocers' paper and a little clean water. They may be freed from oil by means of a little strong nitric acid, after the action of which water will thoroughly clean them. Long sticks with sponges or dry cloths at the end should be provided for wiping dry the interior of flasks and bottles. A wire, bent at the end into a sort of hook, will be found useful for getting corks out of bottles. A loop of twine will also be found a very convenient means of effecting the same object. When the glass stopper of a bottle is fast, it may often be loosened by gently tapping its sides alternately with the handle of a pallet knife. Sometimes a drop or two of oil, alcohol, or water, will soften or dissolve the cementing substance. It will sometimes answer to wrap the stopper in a cloth, insert it in a crevice or hole in a table or door, and twist the bottle gently and dexterously. Sometimes the stopper may be loosened by quickly expanding the neck in the flame of a lamp, and tapping the stopper before the heat has reached it.

The apothecary should be provided with pallet knives of wood, bone, and horn, as well as of steel. It should be an invariable rule to clean every knife and graduated measure immediately after they are used, and to put the dirty mortars apart from those which are clean. Too much particularity and order in all the minute details of the shop cannot be practised. The counters and scales should be cleaned once a day, and brushed as often as they become dusty. The bottles should be replaced as soon after being taken down and used as possible, and should on no account be changed from their accustomed place on the shelf. For the proper preservation of leaves, flowers, aromatic powders, calomel, and other medicines to which light is injurious, the bottles should be coated with tin foil or black varnish.

No apothecary should be destitute of a set of troy weights; as without them he will be utterly unable to comply with the officinal directions for the preparation of his medicines. In dispensing medicines, no vial nor parcel should be suffered to leave the shop without its appropriate label; and this, in the case of prescriptions, should always be the physician's direction as to the manner of taking it, and not the name of the medicine, unless it be so directed by him. The prescription or a copy of it should be retained and numbered, and the same number marked on the bottle or parcel. Every thing connected with the shop, and the dispensing and putting up of medicines and parcels, should be characterized by *neatness*, *accuracy*, *system*, and *competent knowledge*.

The apprentice who desires to qualify himself for his business should carefully study Turner's Elements of Chemistry, and Faraday's invaluable treatise on Chemical Manipulation, which may be termed the hand books of his profession. D. B. S.

As all the processes of the British Colleges are either described or fully detailed in the following pages, it is proper that the prefatory explanations of the several Pharmacopœias should be introduced in this place, in order that the reader may be prepared to understand the precise signification of the terms employed.

The Pharmacopœias recognised in this work unite in the use of the *troy* pound, and its divisions of ounces, drachms, scruples, and grains, for the expression of weights; and the *Edinburgh College* employs no other measure of quantity, whether of solids or liquids. In the *United States* Pharmacopœia, and in those of *London* and *Dublin*, the quantity of fluids is generally indicated by the liquid measure, consisting of the wine gallon and its divisions of pints, fluidounces, fluidrachms, and minims. (See tables of weights and measures in the Appendix.) It is highly necessary that the apothecary should understand that this distinction is rigidly observed in all the details which follow, and that whenever the simple terms pound, ounce, and drachm, are employed, they must be considered as belonging to the denomination of troy weight. This caution is the more necessary, as these terms are often confounded with the corresponding divisions of liquid measure, viz. the pint, fluidounce, and fluidrachm.

The *London College*, in giving the specific gravity of bodies, considers them at the temperature of 55° Fahrenheit, the *Edinburgh* and *Dublin*

Colleges at 60°; and the latter is the degree intended by the United States Pharmacopœia, though not expressly stated.

The *London College* explains the term *gentle heat* as signifying a temperature between 90° and 100°; the *Edinburgh College*, between 90° and 110°. The *Dublin College* employs the terms *superior*, *medium*, and *inferior heat*, the first signifying a temperature between 200° and 212°, the second between 100° and 200°, and the third between 90° and 100°.

Maceration, according to the *Edinburgh College*, is performed at ordinary temperatures; according to the *Dublin*, at a temperature between 60° and 90°. *Digestion* is performed by the latter College at an "*inferior heat;*" by the former, at about 100°, when not otherwise expressed.

The *London* and *Dublin Colleges* direct that mortars, measures, funnels, and other vessels in which medicines are prepared, should be made of materials containing neither copper nor lead. Earthen vessels, therefore, glazed with lead, are improper. The former College also directs that acid, alkaline, earthy, and metallic preparations, and salts of every kind, be kept in stopped glass bottles. W.

ACETA.

Vinegars.

Under this title, in the United States Pharmacopœia, are included both Distilled Vinegar and those preparations usually denominated *Medicated Vinegars.* The latter are infusions or solutions of various medicinal substances in vinegar or acetic acid. The advantage of vinegar as a menstruum is that in consequence of the acetic acid which it contains, it will dissolve substances not readily soluble or altogether insoluble in water alone. It is an excellent solvent of the vegetable alkalies, which it converts into acetates, thereby modifying in some measure, though not injuriously, the action of the medicines of which they are ingredients. As ordinary vinegar contains principles which promote its decomposition, it should be purified by distillation before being used as a solvent. Infusions prepared with it, even in this state, are apt to spoil in a short time; and a portion of alcohol is usually added to contribute to their preservation. A small quantity of acetic ether is said to result from this addition; and, on the continent of Europe, the place of the alcohol is frequently supplied by an equal amount of concentrated acetic acid. In consequence of their liability to change, the medicated vinegars should be made in small quantities, and kept but for a short time. W.

ACETUM DESTILLATUM. *U.S.* ACIDUM ACETICUM DILUTUM. *Lond.;* ACIDUM ACETICUM TENUE. *Ed.;* ACETUM DISTILLATUM. *Dub.* *Distilled Vinegar.*

"Take of Vinegar *a gallon*. Distil the Vinegar by means of a sand-bath, from a glass retort into a glass receiver. Reject the first pint, and preserve the five pints which next come over." *U.S.*

The *London* process for distilled vinegar differs from the above, in directing six pints instead of five to be preserved after the rejection of the first pint, and in ordering a cool receiver. The *Edinburgh* College rejects the first eighth in the distillation, and preserves the succeeding five-eighths; but it continues the distillation afterwards, so long as colourless acid is obtained; and this last portion, being mixed with the first rejected portion, is kept to be applied to various chemical purposes. The *Dublin* College distils wine-vinegar. The first tenth which comes over is rejected, the next eight-tenths are the "distilled vinegar," having the sp. gr. 1.005, and one-tenth is left behind in the retort.

Vinegar is a very heterogeneous liquid, containing colouring matter, mucilage, alcohol, &c.; and the object of its distillation is to purify it. (See *Acetum.*) The first portion which comes over contains alcohol and pyroacetic spirit, these being the most volatile ingredients; next the acetic acid comes over much purified, but weaker than it exists in the vinegar, on account of its being less volatile than water; and there remains in the retort a liquid of a deep brown colour, very sour and empyreumatic, and containing free tartaric and malic acids, bitartrate of potassa, and extractive. This statement explains why the first portion which comes over is rejected, and why the last portion is not distilled, or, if drawn off as directed by the Edinburgh College, is reserved for other than medicinal purposes. The proportion preserved by the Pharmacopœias is different. According to those of the United States and Edinburgh, it is five-eighths of the vinegar employed, according to the London six-eighths, and according to the Dublin eight-tenths. The distillation should certainly be continued as long as the product is free from empyreumatic taste; and we are assured by Dr. Barker, the commentator on the Dublin Pharmacopœia, that eight-tenths of the vinegar may be distilled without empyreuma. If this statement be correct, the Dublin process is the best, as being the most productive, without any sacrifice of the quality of the distilled vinegar. The residuary liquid in the retort, if diluted with an equal bulk of hot water, and mixed with pure animal charcoal in the proportion of half an ounce to the pint, may be made to yield, by a fresh distillation, an additional quantity of weak acetic acid, equally strong and pure with the officinal distilled vinegar. (See *Carbo Animalis.*)

The different Pharmacopœias direct the distillation of vinegar to be conducted in glass vessels; but it is generally distilled in a copper alembic furnished with a pewter worm as a refrigerator. The use of these metals, however, is hazardous, on account of the danger of metallic impregnation. Mr. Brande has suggested that the refrigerator might be made of very thin silver, a metal not acted on by acetic acid of any strength. Empyreuma is effectually prevented by distilling by means of steam. In Great Britain the purification of vinegar by distillation is nearly superseded by the use of purified pyroligneous acid in a dilute state. One pound of this acid mixed with five pounds of water, furnishes a dilute acid of the sp. gr. 1.009, which is about the strength of distilled vinegar.

Properties. Distilled vinegar is a limpid and colourless liquid, of a weak acid taste and smell, less agreeable than those of common vinegar. Its sp. gr. varies from 1.007 to 1.009. A fluidounce of the former specific gravity will saturate 28 grains of carbonate of ammonia, 35 grains of carbonate of potassa, and 58½ grains of crystallized carbonate of soda. It is not a perfectly pure solution of acetic acid in water; but contains a portion of mucilage which rises in the distillation. It is on account of the partial decomposition of this impurity, that distilled vinegar, when saturated with an alkali, is liable to become of a reddish or brownish colour. When distilled in metallic vessels, it is apt to contain traces of copper, lead, and tin. Copper is easily detected by the addition of ferrocyanate of potassa, which produces a brown cloud; lead, by sulphate of soda, which occasions a white precipitate, and tin, by a solution of muriate of gold, which causes a purplish appearance. The two latter metals are discovered also by sulphuretted hydrogen, which occasions a dark-coloured precipitate. Distilled vinegar should not have an empyreumatic taste or sulphureous smell. Malt vinegar contains a small portion of sulphuric acid, but when it is distilled, this acid does not come over. If, however, sulphuric acid should be accidentally present in distilled vinegar, it may be detected by muriate of baryta.

Distilled vinegar is not of uniform strength. When of the sp. gr. 1.007, it contains 3.42 per cent. of anhydrous acid, and 4.73 per cent. of the same acid, when its density is 1.009.

Medical Properties and Uses. The medical properties of distilled vinegar are the same as those of common vinegar (see *Acetum*); but the former being purer, and not liable to spontaneous decomposition, is preferable for pharmaceutical purposes. It is employed as the basis, with but few exceptions, of the two classes of preparations called "Vinegars" and "Oxymels."

Off. Prep. Emplastrum Ammoniaci, *Lond.*, *Ed.;* Hydrargyri Acetas, *Dub.;* Liquor Ammoniæ Acetatis, *Lond.*, *Ed.*, *Dub.;* Liquor Plumbi Subacetatis, *Lond.*, *Dub.;* Oxymel, *Ed.*, *Dub.*, *Lond.;* Plumbi Acetas, *Dub.*, *Ed;* Potassæ Acetas, *Dub.*, *Ed.;* Sodæ Acetas, *Dub.;* Syrupus Allii, *U.S.*

ACETUM COLCHICI. *U.S.*, *Lond.*, *Dub.* *Vinegar of Meadow-saffron.*

"Take of [dried] Meadow-saffron Root, sliced, *two ounces;* Distilled Vinegar *two pints;* Alcohol *a fluidounce.* Macerate the Meadow-saffron Root with the Vinegar, in a close glass vessel, for seven days; then express the liquor, and set it by that the dregs may subside; lastly, pour off the clear liquor, and add the Alcohol." *U.S.*

The *London* and *Dublin Colleges* direct an ounce of the fresh root or bulb, a pint of distilled vinegar, a fluidounce of proof spirit, and a maceration of three days. The resulting preparation may be considered identical with the American; as the dried bulb of our shops is probably not on an average stronger than the fresh bulb in Europe, and the proof spirit of the British Colleges is equivalent to little more than half its bulk of our officinal alcohol.

Vinegar is an excellent solvent of the active principle of colchicum; and the organic alkali of the latter loses none of its efficacy by combination with the acetic acid of the former. The use of the alcohol is simply to retard the spontaneous decomposition to which this, like most of the other medicated vinegars, is liable.

Medical Uses. The preparation has been extolled as a diuretic in dropsy; and may be given in gout, rheumatism, and neuralgia; but the wines of colchicum are usually preferred. The dose is from thirty drops or minims, to a fluidrachm.

Off. Prep. Syrupus Colchici, *U.S.* W.

ACETUM OPII. *Dub.* *Vinegar of Opium.*

"Take of Turkey Opium *four ounces;* Distilled Vinegar *a pint.* Rub the Opium into a pulp with a little of the Vinegar, then add the remainder of the Vinegar. Macerate the mixture in a close vessel for seven days, frequently shaking. Pour off the supernatant liquor: lastly filter."

The vinegar of opium was introduced into the last edition of the Dublin Pharmacopœia, as a substitute for the preparation in common use under the name of *black drop*, the purposes of which it is calculated to answer, without being liable to the same objections. We prefer, however, the

Tinctura Opii Acetata of the United States Pharmacopœia, which has taken the place of the Acetum Opii of the first edition of that work. From the want of alcohol, the Dublin preparation must be liable to spontaneous decomposition, and consequently to variation in strength; and we suspect that there is some waste of opium, as Dr. Montgomery, in his observations upon the Dublin Pharmacopœia, states that twenty drops are equivalent to thirty of the common tincture of opium, though in the preparation of the latter, somewhat less than one-third the quantity of opium is used. For further remarks in relation to the *black drop*, the reader is referred to the article *Tinctura Opii Acetata.* W.

ACETUM SCILLÆ. *U.S., Lond., Dub.* ACIDUM ACETICUM SCILLITICUM. *Ed.* *Vinegar of Squill.*

"Take of Squill, sliced, *four ounces;* Distilled Vinegar *two pints;* Alcohol *a fluidounce.* Macerate the Squill with the Vinegar, in a close glass vessel, for seven days; then express the liquor, and set it by that the dregs may subside; lastly, pour off the clear liquid, and add the Alcohol." *U. S.*

The *London College* directs a pound of recently dried squill, six pints of diluted acetic acid (distilled vinegar), half a pint of proof spirit, and maceration with a gentle heat for twenty-four hours. The *Edinburgh College* directs an ounce of dried squill, fifteen ounces of weak acetic acid (distilled vinegar), an ounce and a half of Alcohol, and maceration for seven days. In the *Dublin* process, the ingredients are in the same proportion as in the London, but in half the quantity; and rectified spirit is employed instead of proof spirit. The maceration is continued, without heat, for seven days.

The process of the last edition of the United States Pharmacopœia, is a great improvement upon that of 1820. In the latter, which was intended to be identical with the Edinburgh process, the proportion of vinegar was increased by the inadvertent adoption of a pint as equivalent to the troy pound; and the liability to spontaneous decomposition was rendered greater by the substitution of vinegar boiled with charcoal, and improperly called "purified vinegar," for the distilled. In the revised process, the proportion of the squill and solvent is the same as in the London and Dublin processes, and the desirable object of uniformity is thus promoted, while a stronger preparation is secured. The quantity of alcohol, which was before unnecessarily large, has been much diminished, and, though rather less than that directed by any of the British Colleges, is deemed sufficient—exceeding considerably the amount ordered in the Paris Codex. The only object of the alcohol is to retard the decompostion of the vinegar of squill; while its presence is medically injurious by rendering the preparation too stimulating. It is best, therefore, to prepare the vinegar frequently, and in small quantities, so as to require little alcohol for its preservation. In the preparation of the oxymel and syrup of squill, for which purpose the vinegar is chiefly used in this country, it should be employed without alcohol. The vinegar of squill deposites, upon standing, a precipitate which consists, according to Vogel, of citrate of lime and tannin.

Medical Uses. This preparation has all the properties of the squill in substance, and is occasionally prescribed as a diuretic and expectorant in various forms of dropsy and of pulmonary disease; but the oxymel and syrup are usually preferred, as they keep better and are less unpleasant to he taste. The dose is from thirty mimims to two fluidrachms; but the latter uantity would be apt to produce vomiting. It should be given in cinnamon-water, mint-water, or some other aromatic liquid calculated to conceal its taste and obviate its nauseating effect.

Off. Prep. Oxymel Scillæ, *U.S.*, *Lond.*, *Dub.;* Syrupus Scillæ, *U.S.*, *Ed.* W.

ACIDUM ACETICUM AROMATICUM. *Ed. Aromatic Acetic Acid.*

"Take of dried Rosemary Tops, dried Sage Leaves, each, *an ounce;* dried Lavender Flowers *half an ounce;* Cloves, bruised, *half a drachm;* Weak Acetic Acid [Distilled Vinegar] *two pounds.* Macerate for seven days, express the liquor, and filter it through paper." *Ed.*

This is a solution of various volatile aromatic oils in distilled vinegar, and serves as a grateful refreshing perfume in the chambers of the sick. It was intended as a simplification of the thieves' vinegar—*vinaigre des quatres voleurs*—formerly esteemed a prophylactic against the plague and other contagious diseases. In the present state of knowledge, it is hardly necessary to observe, that neither the original nostrum, nor its substitute, has any other power of protecting the system against disease, than such as may depend on its slightly stimulant properties, and its influence over the imagination. W.

ACIDUM ACETICUM CAMPHORATUM. *Ed.*, *Dub.* *Camphorated Acetic Acid.*

"Take of Acetic Acid *six fluidounces* [six ounces, *Ed.*]; Camphor *half an ounce;* Rectified Spirit *a sufficient quantity.* Reduce the Camphor to powder by means of the spirit; then add the acid, and dissolve." *Dub.*

The use of the alcohol is simply to facilitate the pulverization of the camphor, and a few drops are sufficient. Acetic acid in its concentrated state readily dissolves camphor. In this preparation, the whole of the camphor is taken up by the acid. In consequence of the powerful chemical agency of the solution, and its extreme volatility, it should be kept in glass bottles accurately fitted with ground stoppers.

The camphorated acetic acid is an exceedingly pungent perfume, which, when snuffed up the nostrils, produces a strongly excitant impression, and may be beneficially resorted to in cases of fainting or nervous debility. It is an officinal substitute for Henry's *aromatic spirit of vinegar.* W.

◆

ACIDA.

Acids.

Acids, in chemical classification, are those compounds which are capable of uniting in definite proportions with alkalies, earths, and metallic oxides, with the effect of producing a combination, in which the properties of its constituents are mutually destroyed. Such combinations are said to be neutral, and are denominated salts. Most acids have a sour taste, and possess the power of changing vegetable blues to red; and though these properties are by no means constant, yet they afford a ready means of detecting acids, applicable in practice to most cases. The above explanation of the nature of an acid is that usually given; but, according to strict definition, acids are compounds having a strong electro-negative energy, and, therefore, possessing a powerful affinity for electro-positive compounds, such as alkalies, earths, and metallic oxides. It is this antithesis in the electrical condition of these two great classes of chemical compounds that gives rise to their mutual affinity;

which is so much the stronger, as their contrast in this respect is greater. In the majority of cases, the electro-negative compound or acid, is an oxidized body, but by no means necessarily so. When it does not contain oxygen, this element is usually replaced by hydrogen. These peculiarities in composition have given rise to the division of acids into *oxacids*, and *hydracids*. *Vegetable acids*, for the most part, contain both oxygen and hydrogen.

A small number only of the acids are used in medicine; but among these are to be found examples of the three kinds above indicated. B.

ACIDUM ACETICUM. *U.S., Dub.* ACIDUM ACETICUM FORTIUS. *Lond.;* ACIDUM ACETICUM FORTE. *Ed.* *Acetic Acid.*

"Take of Acetate of Soda, in powder, *a pound;* Sulphuric Acid *half a pound.* Pour the Sulphuric Acid into a glass retort, and gradually add the Acetate of Soda; then, by means of a sand-bath, distil the Acetic Acid, with a gentle heat, till the residuum becomes dry. The specific gravity of this acid is 1.0634." *U.S.*

"Take of Acetate of Potassa *one hundred parts;* Sulphuric Acid *fifty-two parts.* Put the acid into a tubulated retort, and at different intervals of time, add the Acetate of Potassa, waiting after each addition until the mixture becomes cool. Lastly, with a moderate heat, distil the acid until the residuum is dry. The specific gravity of this acid is 1.074." *Dub.*

"Take of Dried Sulphate of Iron *a pound;* Acetate of Lead *ten ounces.* Having rubbed them together, put them into a glass retort, and distil by means of a sand-bath, with a moderate heat, so long as any acid comes over." *Ed.*

The London College has no formula for preparing acetic acid; but includes it among the articles of the Materia Medica, with the following explanatory remark. "Acetic Acid distilled from wood, [and purified?], the specific gravity of which is 1.046. One hundred grains of this acid will saturate eighty-seven grains of crystallized subcarbonate of soda."

These processes are intended to furnish a strong acetic acid. The *United States* and *Dublin* formulæ are similar, consisting in the decomposition of the acetate of soda or of potassa by sulphuric acid. A sulphate of the alkali is formed, and the disengaged acetic acid distils over. The acetate of soda, however, is on several accounts the best salt for decomposition. Its advantages are, its uniform composition in the crystallized state, its giving rise to a residuary salt (sulphate of soda) easily washed out of the retort, and the abundance in which it can be obtained from the manufacturers of pyroligneous acid. (See *Sodæ Acetas.*) On the other hand, acetate of potassa is a deliquescent salt, and, therefore, liable to contain a variable quantity of water, and to yield an acid of variable strength. Besides, the residue of the process (sulphate of potassa) is not so easily removed from the retort. In either process the acetic acid is apt to pass over, contaminated with a small quantity of sulphurous acid, which, however, may be removed by a redistillation from a little acetate of lead. In the process of the *Edinburgh* College, a double decomposition first takes place, resulting in the formation of sulphate of lead and acetate of iron. Subsequently the latter salt is decomposed, and yields its acetic acid, which distils over; while the sulphate of lead, mixed with the oxide of iron, remains in the retort. This College does not state the specific gravity or saturating strength of its acid. The acid of the *London* College may be considered as obtained in the same way as that of the United States Pharmacopœia; for the acid no doubt *intended* to be designated by the College, is the *purified* acetic acid from wood, and this is made by converting the impure pyroligneous acid into a pure acetate of soda, and decomposing this by sulphuric acid. How the acetate of soda is obtained from the impure acid, is explained under another head. (See *Sodæ Acetas.*)

Of the different officinal acids, the density of which has been specified, the acid of the Dublin College is the strongest, that of the London, the weakest, while the acid of the United States Pharmacopœia is intermediate in its strength. The Dublin acid, when properly prepared, is necessarily stronger than that of our national Pharmacopœia; because acetate of potassa contains but two, while acetate of soda contains six equivalents of water; and it is from the water present in the acetate employed, together with that in the liquid sulphuric acid, that the acetic acid obtained, derives the water with which it is diluted.

Besides the methods above mentioned, there are several others for procuring strong acetic acid. Thus it may be obtained from acetate of lead; and this, according to Berzelius, is the least expensive process that can be adopted. This method consists in distilling with a gentle heat, from a glass retort into a receiver, perfectly effloresced acetate of lead with three-tenths of its weight of concentrated sulphuric acid; the materials being stirred immediately with a glass rod, in order that they may be thoroughly mixed. Acetic acid, obtained in this way, has always the odour of sulphurous acid, from which it may be freed by the addition of a small portion of peroxide (brown oxide) of lead. This converts the sulphurous into sulphuric acid, which immediately combines with the lead reduced to protoxide, and forms a sulphate, insoluble in the acetic acid. Another method for obtaining this acid, adopted in the Paris Codex, is by the destructive distillation of the acetate of copper (crystals of Venus). The distillation must be performed in a stoneware retort, and is described in detail by Thenard. The water of crystallization of the salt being evaporated before the acid begins to rise, there is a deficiency of the former liquid, necessary to hold the elements of the acetic acid together. Accordingly, a part of the acid is decomposed, being resolved into water, and a peculiar volatile compound called *pyroacetic spirit*, which gives to the acid product a peculiar fragrant smell. The sp. gr. of the acid thus obtained is 1.075. Both the methods for obtaining acetic acid, last described, are liable to the objection that the acid produced is apt to contain metallic matter; and hence the acid, when thus procured, is generally directed to be purified by a new distillation. But even after this step, some doubt may be entertained as to its entire safety for medicinal employment.

Properties. The acetic acid of the Pharmacopœias is a limpid and colourless liquid, possessing a very sour and acrid taste, and a fragrant pungent smell. It unites in all proportions with water, and dissolves to a certain extent in alcohol. It possesses the property of dissolving a number o substances, such as the volatile oils, camphor, gluten, resins and gum-resins. fibrin, albumen, &c. When well prepared, it should not form a precipitat with the soluble salts of baryta, and should evaporate completely in a glas or platinum capsule, without leaving any residue. The presence of copper lead, or tin, may be detected by neutralizing the acid with ammonia, an testing successively with ferrocyanate of potassa, sulphate of soda, and sulphuretted hydrogen, in the manner explained under *Acetum Destillatum* This acid consists of the strongest liquid acetic acid (radical vinegar) dilute with a variable quantity of water. The acid of the United States Pharmacopœia contains about 50 per cent. of water of dilution; that of the Dubli College, about 34 per cent. In this estimation, the water in a state of combination in the radical vinegar, and which is essential to its existence in th liquid state, is not included. Admitting 50 per cent. of water of dilutio in the U.S. acid, it would contain 42.5 per cent. of absolute or dry acetic acid.

Acetic acid as concentrated as possible, or *radical vinegar*, is a colourless liquid at the temperature of 60°, possessing a strongly acid and corrosive taste, and an acid, pungent, and refreshing smell. At the temperature of 55° it becomes a crystalline solid. Its sp. gr. is 1.063. In the state here described, it consists of one equiv. of dry acid 51.48, and one of water 9 = 60.48. When diluted with water, its density increases until it reaches 1.079, when its sp. gr. is at the maximum, after which further dilution renders it lighter. This statement shows that specific gravity is not an accurate test of the strength of this acid; but as the ordinary samples of the acid are not likely to be deficient in density from extreme concentration, they may without risk of error be estimated as stronger in proportion as this is greater. The best means, however, of determining the strength of the acid, is by ascertaining its saturating power, as this method is not liable to ambiguity. This acid is one of the few vegetable acids that volatilize without decomposition. Its boiling point is somewhat higher than that of water. When boiled in open vessels, it takes fire and burns with a blue flame like alcohol. As it attracts humidity from the atmosphere, it should be preserved in well stopped bottles. Its combinations with salifiable bases are called acetates. It consists, as a dry acid, of three equivalents of hydrogen 3, four of carbon 24.48, and three of oxygen 24 = 51.48.

Medical Properties and Uses. Acetic acid acts as a stimulant and rubefacient. Owing to its volatility and pungency, its vapour is frequently applied to the nostrils as an excitant in syncope, asphyxia, and headach. When employed in this manner, it is generally added to a small portion of sulphate of potassa, so as to moisten the salt, and the mixture is put in small glass bottles with ground stoppers. As a rubefacient it operates with considerable activity, producing burning heat and much redness and inflammation, which terminates by the peeling off of the cuticle. It is sometimes employed as a substitute for a fly blister, where the speedy production of a counter-irritant impression is desired, as for example, in croup, sorethroat, and other cases of internal inflammation. It may be applied by means of blotting paper or cambric moistened with the acid. It is also a good application to warts and corns, the vitality of which it frequently destroys.

Off. Prep. Acidum Aceticum Camphoratum, *Ed.*, *Dub.*; Acidum Aceticum Dilutum, *U.S.*; Morphiæ Acetas, *U.S.* B.

ACIDUM ACETICUM DILUTUM. *U.S. Diluted Acetic Acid.*

"Take of Acetic Acid *half a pint*; Distilled Water *five pints*. Mix them."

The acid resulting from the above formula is peculiar to the United States Pharmacopœia; but, unfortunately, the name by which it is designated is applied by the London College to distilled vinegar. The object of having this preparation, is to possess a weak solution of pure acetic acid, which may be substituted for distilled vinegar in all formulæ in which nicety is required. Distilled vinegar contains a portion of mucilage, which is always darkened or precipitated when this acid is saturated with an alkali, an occurrence which cannot take place when the dilute acetic acid of our Pharmacopœia is employed. As the *Acidum Aceticum* (U.S.) contains 42.5 per cent. of dry acid, it is easily determined by a calculation that the *Diluted Acetic Acid* will contain 3.86 per cent. of the same acid, which is about the average strength of distilled vinegar as ascertained by Mr. Phillips.

Off. Prep. Liquor Ammoniæ Acetatis, *U.S.* B.

ACIDUM BENZOICUM. *U. S., Lond., Ed., Dub.* *Benzoic Acid.*

"Take of Benzoin *any quantity.* Put the Benzoin into a glass vessel placed in a sand-bath; and with a heat of 300° gradually increased, sublime until nothing more ascends. Wrap the sublimed matter in bibulous paper, and press it, that it may be separated from the oily part; then again sublime with a heat not exceeding 400°." *U.S.*

This process is identical with that of the *London* Pharmacopœia, from which it was adopted.

The *Edinburgh* College gives the following. *Two pounds* of benzoin, previously triturated with *eight ounces* of carbonate of soda, are boiled in *sixteen pounds* of water, with constant agitation, for half an hour. The decoction is then strained; and the residue of the benzoin is boiled with other *six pounds* of water, which are also strained. The decoctions are mixed, and evaporated to two pounds. The remaining liquid is filtered, and diluted sulphuric acid dropped into it so long as any precipitate is afforded. The precipitated benzoic acid is dissolved in boiling water; and the solution while still hot is strained through linen, and set aside to crystallize. The process is completed by washing the crystals with cold water, and drying them.

According to the *Dublin* process, *five parts* of benzoin, triturated with *one part* of fresh quicklime, are boiled in *one hundred and thirty parts* of water for half an hour, the mixture being constantly stirred with a rod. After having cooled, the clear liquor is decanted, and the residue is boiled with *seventy parts* of water, which is also decanted when cold. The liquors having been mixed are evaporated to one-half, and filtered through paper; and *one part* of muriatic acid is gradually added. The precipitate produced is separated from the supernatant liquid, washed with a small quantity of cold water, dried with a gentle heat, and submitted to sublimation in a proper apparatus.

Of the above processes, the first is most simple and easy. The acid, which exists in the benzoin combined with resin, is volatilized by the heat, and condensed in the upper part of the apparatus. Unless the temperature is very carefully regulated, a portion of the resin is decomposed, and an oily substance generated, which rises with the acid and gives it a brown colour, from which it cannot be entirely freed by bibulous paper; and this result sometimes takes place even with the greatest caution. The process for subliming benzoic acid is usually conducted in a glazed earthen vessel, surmounted by a cone of paper, or by another vessel with a small opening at top, and a band of paper pasted round the place of junction. After the heat has been applied for an hour, the process should be suspended till the condensed acid is removed from the upper vessel or paper cone, when it may be renewed, and the acid again removed, and thus alternately till coloured vapours rise. The remaining acid of the benzoin may be extracted if deemed advisable, by treating the balsam with lime or carbonate of soda. From this mode of preparing benzoic acid it was formerly called *flowers of benzoin*.

By the Edinburgh and Dublin processes, the acid is extracted from the benzoin by combining it with a salifiable base, and is subsequently precipitated by an acid. It is purified, in the one case, by dissolving it in boiling water, which throws it down upon cooling; in the other, by sublimation, which gives it the peculiar silky lustre which distinguishes it. The process of the Dublin College is essentially that of Scheele, the process of the Edinburgh College that of Gren. They both afford a purer product than that obtained by sublimation, but not preferable in a medicinal point of view, as the small quantity of oil present in the sublimed acid adds to its stimulant properties, and at the same time renders it pleasant to the smell.

Several other modes of extracting the acid have been recommended by different chemists. The following is the process of Stolze. One part of the balsam is dissolved in three parts of alcohol, the solution filtered and introduced into a retort, and the acid saturated by carbonate of soda dissolved in a mixture of eight parts of water and three of alcohol. The alcohol is distilled off; and the benzoate of soda contained in the residuary liquid is decomposed by sulphuric acid, which precipitates the benzoic acid. This is purified by solution in boiling water, which lets fall the acid when it cools.

By the above process Stolze obtained 18 per cent. of acid from benzoin containing 19.425 per cent. By the process of Scheele (that of the Dublin College) he obtained 13.5 per cent.; by the agency of carbonate of soda, as in the Edinburgh process, 12 per cent.; by sublimation only 7.6 per cent. Nevertheless Mr. Brande says that the last process is on the whole the most economical. According to this author, good benzoin affords by sublimation from 10 to 12 per cent. of the acid contaminated with empyreumatic oil, and about 9 per cent. of the purified acid.

Properties. Sublimed benzoic acid is in soft, white, feathery crystals, of a silky lustre, and not pulverulent. From solution the acid crystallizes in transparent prisms. When quite pure it is inodorous; but prepared by sublimation from the balsam, it has a peculiar agreeable aromatic odour, dependent on the presence of an oil, which may be separated by dissolving the acid in alcohol, and precipitating it with water. Its taste is warm, acrid, and acidulous. It is unalterable in the air, but at 230° melts, and at a somewhat higher temperature rises in suffocating vapours. It is inflammable, burning without residue. It is very sparingly soluble in cold, but is dissolved by about twenty-four parts of boiling water. It is soluble in alcohol, and in concentrated sulphuric and nitric acids, from which it is precipitated by water. The fixed oils also dissolve it. Its solution reddens litmus paper, and it forms salts with salifiable bases; but its acid properties are not powerful. According to Berzelius, in consists of 75.36 parts of carbon, 4.92 of hydrogen, and 19.72 of oxygen in the hundred. It is a characteristic constituent of the balsams, and has been found in various other vegetable, and in some animal products.

Medical Properties and Uses. Benzoic acid is stimulant, and has been thought to be expectorant; but is not now used internally except as a constituent of one or two officinal preparations. The dose is from 10 to 30 grains. It is an ingredient in some cosmetic washes, and has been employed by way of fumigation as a remedy in affections of the skin.

ACIDUM HYDROCYANICUM. *U.S.* ACIDUM PRUSSICUM. *Dub.* *Hydrocyanic Acid. Prussic Acid.*

"Take of Cyanuret of Mercury *an ounce*; Distilled Water *eight fluidounces and a half;* Carbonate of Lead *a sufficient quantity*. Dissolve the Cyanuret of Mercury, with a gentle heat, in the Distilled Water; pass Hydrosulphuric Acid through the solution, in a proper vessel, till it is fully saturated; then filter through paper. To the filtered liquor add a quantity of Carbonate of Lead more than sufficient to saturate any excess of Hydrosulphuric Acid, and agitate them well together. Lastly, again filter through paper.

"The Hydrocyanic Acid prepared by this process, is of the same density with that of Scheele.

"Hydrosulphuric Acid is obtained from the Sulphuret of Iron, and Sulphuric Acid diluted with four times its weight of water." *U.S.*

"Take of Cyanuret of Mercury *an ounce;* Muriatic Acid *seven fluidrachms;* Water *eight fluidounces.* From a glass retort, distil into a refrigerated receiver, *eight fluidounces*, to be kept in a well stopped bottle, in a cool and dark place. The specific gravity of this acid is 0.998." *Dub.*

Hydrocyanic or prussic acid was first brought into general notice as a remedy by Magendie in 1817. It was admitted as an officinal article into the Paris Codex in 1818, into the first edition of the United States Pharmacopœia in 1820, and into the revised edition of the Dublin Pharmacopœia in 1826. As yet it has not been recognised by the London or Edinburgh College.

The process of the *United States* Pharmacopœia of 1820 for obtaining the acid, was that of Scheele; but as this process produced an acid of variable strength, it was thought advisable, in the revision of 1830, to substitute the process of Proust, (generally attributed to Vauquelin,) as laid down in the Paris Codex. By this process the cyanuret (bicyanuret) of mercury, in solution of definite strength, is decomposed by a stream of hydrosulphuric acid gas (sulphuretted hydrogen.) The proportions for mutual decomposition, are one equiv. of the bicyanuret, and two of hydrosulphuric acid. Two equiv. of hydrogen from the acid, combine with the two equiv. of cyanogen in the bicyanuret, forming two equiv. of hydrocyanic acid which dissolve in the water; while the two equiv. of sulphur form with the one equiv. of mercury, one equiv. of bisulphuret of mercury, or cinnabar, which precipitates. Filtration would now complete the process, were it not that the filtered solution is apt to retain a little hydrosulphuric acid. To remove this, an excess of carbonate of lead is added, which converts it into insoluble sulphuret of lead. By a new filtration, the sulphuret, as well as any excess of carbonate of lead, is removed, and the clear liquor consists of hydrocyanic acid, diluted to a certain extent with water.

The process of the U.S. Pharmacopœia is liable to the objection, that the acid product is apt to contain a little oxide of lead, even after the most careful filtration. This may arise from the presence of some oxide in the carbonate of lead employed; or possibly the hydrocyanic acid may decompose a small portion of the carbonate itself. To obviate this objection to the process, it would, perhaps, be an improvement, if the acid, as obtained by the officinal directions, were submitted to distillation, which would effectually free it from the impurity in question.

The *Dublin* process is that of Gay-Lussac, with the use of a certain amount of water of dilution. The rationale is precisely similar to that just given, the chlorine of the muriatic acid in this process performing exactly the same part as the sulphur in the other. Consequently the residue here is the bichloride of mercury, or corrosive sublimate. The Dublin College uses a little more than the equivalent quantity of muriatic acid, to ensure the complete decomposition of the bicyanuret.

The process adopted in the United States Pharmacopœia is preferable to that of the Dublin College, on account of its greater facility and productiveness. The acid obtained is stated to be equivalent in strength to that procured by Scheele's process; but this statement is not very definite, as we have already mentioned that Scheele's process gives an acid of variable strength. To remove uncertainty on this point, we have had the process of the United States Pharmacopœia repeated, and the acid obtained is found to have the sp. gr. 0.998 at the temperature of 60°, which is the same density as that of the Dublin acid. That made at Apothecaries' Hall, London, weighs 0.995. The process pursued at this establishment is to put a pound of bicyanuret of mercury into a tubulated retort with six pints of water, and a pound of muriatic acid of the sp. gr. 1.15. A capacious receiver is luted on and six pints are distilled over.

The Paris Codex gives three processes for obtaining hydrocyanic acid; namely, Proust's (Vauquelin's), Robiquet's, and Scheele's. The first of these is that adopted in the United States Pharmacopœia, and has already been explained. The second is essentially the same as that of the Dublin College, differing only in the details. The first step of it is to distil the bicyanuret with strong muriatic acid, whereby the concentrated acid of Gay-Lussac, weighing 0.700, is obtained, which is then mixed with twice* its weight of distilled water. Thus diluted, it has the sp. gr. 0.900. Scheele's process, as given in the Codex, is as follows:—128 parts of ferrocyanate of iron (Prussian blue) and 64 parts of red oxide of mercury are boiled with 500 parts of distilled water for fifteen minutes, the mixture being constantly stirred. The whole is then filtered, and the insoluble residue washed with 128 parts of boiling distilled water. The filtered liquors are then mixed, and to these are added, 96 parts of finely levigated iron filings, and 24 parts of sulphuric acid, previously diluted with 24 parts of distilled water. The whole is stirred, and afterwards allowed to remain at rest for an hour, (the vessel being immersed in cold water,) in order that the insoluble matter may subside. The clear solution is then subjected to distillation, and 192 parts drawn off. The distilled product is next mixed with 8 parts of carbonate of lime, and redistilled, 128 parts only being drawn off. In this process, the boiling together of Prussian blue and peroxide of mercury generates the bicyanuret of mercury. (See *Hydrargyri Cyanuretum.*) When this solution is mixed with diluted sulphuric acid and iron filings, water is decomposed; its oxygen converts the iron into protoxide, which combines with the sulphuric acid to form sulphate of iron, while its hydrogen combining with the cyanogen, generates hydrocyanic acid. In the meantime the mercury is thrown down in the metallic state. The clear solution, therefore, contains sulphate of iron and hydrocyanic acid, the latter of which alone comes over when the liquid is distilled. The object of the second distillation from chalk, is to free the acid from colour.

---

* The Paris Codex says an equal weight of distilled water; but this is an error, as Robiquet's formula directed Gay-Lussac's acid to be diluted with twice its weight of water. But even when diluted to this extent, the acid is much stronger than it would be safe to use as a medicine. Gay-Lussac's acid being anhydrous, the acid proposed by Robiquet would contain thirty-three and one-third per cent. of real acid! The acid obtained by the use of sulphuretted hydrogen in the Codex, is much weaker than Robiquet's; but is nevertheless alleged to be of the same strength. The apothecaries of Paris, aware of the dangerous strength of the acid of the Codex (Robiquet's,) are in the habit of putting up in prescriptions, an acid prepared with one part of Gay-Lussac's acid to forty parts of water, which gives a preparation containing 2.4 per cent. of real acid. On account of the difference in strength of different samples of medicinal hydrocyanic acid and its liability to decomposition, Messrs. Robiquet and Villermé have proposed to substitute for it the *cyanuret of potassium*, which is a permanent compound, not liable to change. It is made by exposing ferrocyanate of potassa to a long continued red heat in a crucible; whereby the ferrocyanic acid is decomposed, and a dark mass remains, consisting of cyanuret of potassium mixed with charcoal and iron. From this mass the cyanuret may be dissolved, and the solution, when evaporated to dryness, furnishes the substance in the solid state. It should be kept in this state; as it is liable to undergo decomposition when dissolved. The dose is one quarter of a grain, to be gradually increased to a grain. It should be given in solution.

The processes above given are intended to furnish a *dilute* hydrocyanic acid for medicinal purposes. The methods of obtaining the *anhydrous* or *pure* acid are somewhat different. Vauquelin's process is to pass a current of hydrosulphuric acid gas over the bicyanuret of mercury contained in a glass tube, connected with a refrigerated receiver. The first third only of the tube is filled with the bicyanuret; the remaining two-thirds being filled, half with carbonate of lead, and half with chloride of calcium. This process is precisely similar to Proust's, only performed in the dry way. The hydrocyanic acid being generated in the first third of the tube, is driven forward by a gentle heat into the refrigerated receiver. By passing through the carbonate of lead and chloride of calcium, it is successively freed from any traces of hydrosulphuric acid and of water which it may contain. Gay-Lussac's process, already alluded to, consists in distilling the bicyanuret with *strong* muriatic acid into a refrigerated receiver. Between the retort and receiver is interposed a tube filled, one half with fragments of marble and the rest with chloride of calcium. The distilled acid, by passing through these, is purified from muriatic acid and water, and condenses in the cooled receiver in the anhydrous state. The rationale of this process has already been given. The residue in the retort is of course corrosive sublimate. Another process for the anhydrous acid, less expensive than the above, is that of Gautier, the details of which are thus given by Berzelius. The ferrocyanate of potassa is fused without access of air, whereby it is converted into a mixture of cyanuret of potassium and carburet of iron. The mass obtained, after being pulverized and placed in a flask, is slightly moistened with water, and acted on with muriatic acid, added by small portions at a time. The flask is then plunged into hot water, which causes the hydrocyanic acid to be disengaged in the form of vapour. This is passed through a tube containing chloride of calcium, and finally received in a small flask, kept cold by a freezing mixture, where it is condensed. Berzelius inclines to give the preference to this process over all others for obtaining the anhydrous acid; as the salt employed is cheap, and as the temperature of the hot water, while it is competent to volatilize the hydrocyanic acid, is not sufficient to drive over any muriatic acid.

Properties of the Medicinal Acid. Hydrocyanic acid, in the dilute state in which it is used in medicine, is a transparent, colourless, somewhat volatile liquid, possessing a taste at first cooling, afterwards somewhat irritating, and a smell resembling that of bitter almonds. It is liable to undergo decomposition if exposed to the light; but is easily kept if the bottle containing it is covered with black paint, or black paper. Its most usual impurities are sulphuric and muriatic acids; the former of which may be detected by evaporating a small portion of the suspected acid, when this impurity will remain; and the latter by saturating with ammonia, and exposing the liquid to a temperature not exceeding 212°, when the hydrocyanate of ammonia will be dissipated, and muriate of ammonia left. If lead be present, it may be detected by means of hydrosulphuric acid gas, which will cause a blackish precipitate. It is incompatible in prescriptions with nitrate of silver, the salts of iron and copper, and most of the salts of mercury. The medicinal acid is of different strengths, as ordered by different pharmaceutical authorities; its particular strength being denoted by the specific gravity, which is always lower in proportion as it is stronger. The taking of the specific gravity, however, is not a mode of determining the strength, which is convenient for the majority of apothecaries; as slight differences in density indicate very material differences in strength. It is on this account that Dr. Ure has proposed another method, which consists in ascertaining the quantity of red oxide of mercury which a given weight of the acid will dissolve. In applying this test, any convenient weight of the acid, for example one hundred grains, are to be taken, and forty or fifty grains of the mercurial oxide, well pulverized and dried, are weighed out. The latter is then to be added to the former, by small portions at a time, as long as it is dissolved; the solution being assisted by agitation. What remains of the oxide unexpended, deducted from the whole quantity weighed out, will give the portion dissolved. The equivalent quantities of oxide and acid for mutual decomposition, are one equiv. of the former 218, to two of the latter 54.78; as these proportions contain the proper quantities of mercury and cyanogen to form a bicyanuret. Consequently, the oxide dissolved will be to the anhydrous acid present, as 218 to 54.78, or as 4 to 1 nearly. Hence we have the simple rule of dividing the weight of oxide dissolved by 4, and the quotient will represent, with sufficient precision, the quantity of anhydrous acid present. The strength of the medicinal acid may also be ascertained by nitrate of silver, which forms a precipitate, every 134.39 parts of which indicate 27.39 of real acid. Both these tests, however, are inapplicable, if the hydrocyanic acid contains muriatic acid. The strength of the different medicinal acids, expressed by indicating the percentage of anhydrous acid, varies considerably. Thus the acid of the United States Pharmacopœia, assuming its sp. gr. to be 0.998, contains 1.6 per cent. of real acid, and the Dublin acid has the same strength. That of Apothecaries' Hall contains as much as 3.2 per cent. of real acid.

Properties of the Anhydrous Acid. Hydrocyanic acid, perfectly free from water, is a colourless, transparent, inflammable liquid, of extreme volatility, boiling at 80°, and congealing at 5°. Its sp. gr. as a liquid is 0.6969, at the temperature of 64°; and as a vapour 0.9423. Its taste is at first cooling, afterwards burning, with an after-taste in the throat like that of bitter almonds; but from its extremely poisonous nature, it must be tasted with the utmost caution. Its odour is so strong as to produce immediate headach and giddiness. Both water and alcohol dissolve it readily. It is much more prone to undergo decomposition than the dilute acid. In the course of a few hours it sometimes begins to assume a reddish-brown colour, which becomes gradually deeper, till at length the acid is converted into a black liquid, which exhales a strong smell of ammonia. It is a very weak acid in its chemical relations, and reddens litmus but slightly. With salifiable bases it forms salts called hydrocyanates, which are very liable to undergo decomposition. Though usually a product of art, it exists in nature in the cherry-laurel, bitter almond, bird-cherry, peach, and some other plants.

Composition, &c. Hydrocyanic acid consists of one equiv. of cyanogen 26.39, and one of hydrogen 1=27.39; or in volumes, of one volume of cyanogen and one volume of hydrogen without condensation. *Cyanogen* is a colourless gas, of a strong and penetrating smell, inflammable, and burning with a beautiful bluish-purple flame. Its sp. gr. is 1.8157. It was discovered in 1815, by Gay-Lussac, who considers it a compound radical, which, when acidified by hydrogen, becomes hydrocyanic acid. It consists of two equiv. of carbon 12.24, and one of nitrogen 14.15=26.39; or in volumes, of two volumes of the vapour of carbon, and one volume of nitrogen, condensed into one volume. The ultimate constituents of hydrocyanic acid are, therefore, two equiv. of carbon, one of nitrogen, and one of hydrogen.

Hydrocyanic acid, in a dilute state, was discovered in 1780 by Scheele, who correctly stated its constituents to be carbon, nitrogen, and hydrogen; but the peculiar way in which they are combined was first demonstrated by Gay-Lussac, by whom also the anhydrous acid was first obtained.

Medical and Toxicological Properties. Hydrocyanic acid is the most deadly poison known, proving, in many cases, almost instantaneously fatal. One or two drops of the pure acid are sufficient to kill a vigorous dog in a few seconds. After death no trace of irritability can be detected in the muscles. Notwithstanding its tremendous energy as a poison, it has been ventured upon in a dilute state as a medicine. Though occasionally resorted to as a remedy previously to 1817, it did not attract much attention until that year, when Magendie published his observations on its use in diseases of the chest, and recommended its employment to the profession. Its medical virtues are those of a powerful sedative, and, accordingly, it has been used in diseases attended with irritation and pain. It has been most highly recommended and extensively used in complaints of the respiratory organs. It is supposed to exert a control over pulmonary inflammation, after the first edge of excitement has been taken off by blood-letting, and no doubt, in many instances, has been found beneficial under such circumstances. In tuberculous phthisis, though at one time boasted of as a remedy, it has no power whatever, except as a palliative for the cough. In the various affections of the chest, however, attended with dyspnœa or cough, such as asthma, hooping cough, and chronic catarrh, its use has often been decidedly beneficial, by allaying irritation or relaxing spasm. In hypertrophy of the heart, and aneurism of the aorta, it has also been used with advantage. In various affections of the stomach, attended with pain and imperfect digestion, hydrocyanic acid, conjoined with tonics, has proved beneficial in the hands of some practitioners. Sometimes it is used externally, diluted with water, as a wash in cutaneous diseases. Dr. A. T. Thomson, from his personal experience, insists particularly on its efficacy in allaying the itching and tingling in impetiginous affections.

The dose of medicinal hydrocyanic acid is from one to six or eight drops dissolved in distilled water, or rubbed up with mucilage of gum Arabic or almond emulsion. It requires to be administered with the greatest caution, on account of the minuteness of the dose, and the great variableness in strength of the acid as found in the shops. The proper plan, therefore, is to begin with a small dose, one drop for example, and gradually to increase the dose, until some obvious impression is produced. If giddiness, weight at the top of the head, sense of tightness of the stomach, or faintness, come on, its use should be discontinued. In all cases in which a fresh portion of medicine is used, the dose should be lowered to the minimum, for fear the new sample might prove stronger than that previously employed. When resorted to as a lotion, from thirty minims to a fluidrachm may be mixed with a fluidounce of distilled water.

Hydrocyanic acid is so rapidly fatal as a poison, that physicians have seldom to treat its effects. When not immediately fatal, the symptoms produced are sudden loss of sense, trismus, difficult and rattling respiration, coldness of the extremities, a smell of bitter almonds proceeding from the mouth, smallness of the pulse, swelling of the neck, dilatation and immobility of the pupil, convulsions, &c. The first measure to be taken in the treatment is the administration of a strong emetic, if the practitioner be called immediately, otherwise a purgative enema. Next frictions with tincture of cantharides and ammonia, sinapisms to the feet, and mucilaginous drinks are to be employed. In case of cerebral congestion, bleeding from the jugular, or leeching behind the ears, will be proper. As a stimulant, a teaspoonful of oil of turpentine may be given from time to time with advantage. Diluted water of ammonia, mentioned by some authorities as an antidote, is not, according to Orfila, entitled to that appellation. Berzelius, however, considers it the best counterpoison, which we possess against this acid.

After death from suspected poison, it is sometimes necessary, in medico-legal investigations, to ascertain whether the event was caused by this acid. Lassaigne has indicated, as a very delicate test, the use of sulphate of copper. The stomach should be cut up, and, with its contents, mixed with a small quantity of water, and the mixture submitted to distillation. When about an eighth of the water has come over, a drop of caustic potassa is added to it, and immediately afterwards, a small quantity of the sulphate of copper. The alkali will cause a precipitate of peroxide of copper; but if hydrocyanic acid be present, a cyanuret of copper will also be formed. To ascertain the presence of the latter, one or two drops of muriatic acid are to be added, which will dissolve the peroxide of copper, and leave the cyanuret diffused through the liquid, so as to give it a milky appearance. B.

ACIDUM MURIATICUM DILUTUM. *Dub.* *Diluted Muriatic Acid.*

"Take of Muriatic Acid, *by measure, ten parts.* Distilled Water, *by measure, eleven parts.* Mix. The specific gravity of this acid is 1.080." *Dub.*

This preparation, which is peculiar to the Dublin College, contains about sixteen per cent. of real acid. It is more convenient for exhibition than the strong acid; and its introduction may, therefore, be viewed as an improvement. For an account of its medical properties the reader is referred to the article *Acidum Muriaticum.* Its dose is from ten to fifty drops, mixed with water or other convenient vehicle. It is employed by the Dublin College in the preparation of the *Calcis Phosphas Præcipitatum.* B.

ACIDUM NITRICUM DILUTUM. *Lond., Dub.* ACIDUM NITROSUM DILUTUM. *Ed.* *Diluted Nitric Acid.*

"Take of Nitric Acid *a fluidounce;* Distilled Water *nine fluidounces.* Mix." *Lond.*

"Take of Nitric Acid, *by measure, three parts;* Distilled Water, *by measure, four parts.* Mix, avoiding the noxious vapours. The specific gravity of this acid is 1.280." *Dub.*

"Take of Nitrous Acid and of Water *equal weights.* Mix them, taking care to avoid the noxious vapours." *Ed.*

These formulæ are intended to furnish a nitric acid of convenient strength for medical use. The U. S. Pharmacopœia has no corresponding preparation. The British Colleges do not agree in the strength which they direct for it. The acid of the London College contains 14.2 per cent. of strong nitric acid, and has a sp. gr. of 1.08; that of the Dublin College contains nearly 48 per cent., and that of the Edinburgh, 50 per cent. The acid, therefore, of the Dublin and Edinburgh Colleges is more than three times as strong as that of the London Pharmacopœia. These discrepancies are to be regretted; but we incline to the opinion that the strength of the London acid is the most convenient. The formula of the Edinburgh College would seem to give a diluted nitrous, instead of nitric acid; but the fact is, that the nitric oxide, the presence of which forms the essential character of the pharmaceutical nitrous acid, is extricated during the dilution.

The medical properties of the diluted acid are the same as those of the strong acid. (See *Acidum Nitricum.*) The dose of the London acid is from twenty to forty drops three times a day; that of the other Colleges, one-third this quantity. It is employed pharmaceutically by the Edinburgh and Dublin Colleges in preparing the nitrate of silver, subnitrate of bismuth, red precipitate, acetate of mercury, and precipitated calomel. B.

ACIDUM NITROMURIATICUM. *Dub.* *Nitromuriatic Acid.*

"Take of Nitric Acid, *by measure, one part;* Muriatic Acid, *by measure, two parts.* Mix the Acids in a refrigerated vessel, and keep the mixture in a well stopped bottle, in a cool and dark place." *Dub.*

This is the *aqua regia* of the earlier chemists, so called from its property of dissolving gold. Nitric and muriatic acids, when mixed together, mutually decompose each other. The equivalent quantities, necessary to render the decomposition complete, are one equiv. of each. One equiv. of hydrogen of the muriatic acid forms water with one equiv. of oxygen of the nitric acid, which consequently becomes reduced to the state of nitrous acid, and chlorine is set free. The preparation, therefore, after the reaction has taken place, consists of a solution of nitrous acid and chlorine in water.

As the acids, considered dry, must be used in the proportion of their equivalents, it is easy to calculate in what proportions the officinal acids of the U. S. Pharmacopœia must be mixed, so as to contain equivalent quantities of the dry acids. Thus 67.7 parts of the U.S. nitric acid contain one equiv. of dry acid; and 114.4 parts of the U.S. muriatic acid, one equiv. of dry acid also. It hence follows that the U.S officinal acids, for complete decomposition, must be mixed in the proportion of 67.7 parts by weight of nitric acid to 114.4 of muriatic acid, or of 10 to 17 nearly; and the mixture will contain by calculation somewhat less than 20 per cent. of free chlorine, assuming that none is lost by effervescence. As the Dublin and U.S. officinal muriatic acids coincide in sp. gr., and their nitric acids differ in sp. gr. only as 1.49 to 1.5, the above calculations are virtually applicable to the Dublin acids. And by a calculation, it may be easily determined, that the proportion given in the Dublin formula of one measure of nitric acid to two of muriatic is, theoretically, nearly correct, being in weight as 10 to 16 nearly; which numbers give a slight excess of the nitric acid, an error on the right side, as it ensures the total decomposition of the muriatic acid.

The affinity of chlorine and nitrous acid for water being much less than that of muriatic and nitric acid for the same liquid, the mixture of the *strong acids* is always attended with the production of effervescence; and great care should be taken to preserve the nitromuriatic acid, thus formed, in strong vessels, and in a cool, dark place. To prevent the loss of chlorine, Dr. Duncan recommends the immediate dilution of the mixture with an equal quantity of water. On account of these objections to the use of the strong acids, it is best to employ good *ordinary acids* of commerce. The strength of these may be stated as averaging 1.15 for muriatic, and 1.34 for nitric acid; and the proportions in which they should be mixed is about 26 parts by weight of the former to 25 of the latter. The mixture contains about 15 per cent of chlorine. The decomposition, in this case, takes place slowly, and the resulting solution of chlorine may be kept with perfect safety.

Properties. Nitromuriatic acid has a golden-yellow colour, and emits the smell of chlorine. It requires to be kept in a cool, dark place, on account of its liability to lose its chlorine by heat, or to have it converted, by the action of light, into muriatic acid, in consequence of the decomposition of water. The nitric and muriatic acids, as occasionally sold in the shops, are so weak that when mixed they will not readily act on gold-leaf. When this is the case, their solvent power may be rendered effective by the addition of a little sulphuric acid, which, by its superior attraction for water, concentrates the others, and produces an immediate action, accompanied by the evolution of chlorine.

Medical Properties and Uses. Nitromuriatic acid has been introduced into the Dublin Pharmacopœia, probably on account of the favourable report of its efficacy as an external remedy in hepatitis, made by Dr. Scott of Bombay. When thus employed, it produces a tingling sensation of the skin, thirst, and a peculiar taste in the mouth; and at the same time stimulates the liver, as is evinced by an increased flow of bile. It is used either by sponging, or in the form of bath. When applied in the former way, the acid is first diluted so as to have the acidity of strong vinegar. When used as a bath, three gallons of water contained in a deep narrow tub, may be acidulated with six fluidounces of the acid. In this the feet and legs are to be immersed for twenty minutes or half an hour. The bath may be employed at first daily, and afterwards thrice or twice a week; and the sponging may be used at the same time. The acid may be used also internally. The dose in this case is two or three drops, sufficiently diluted with water.*

B.

ACIDUM SUCCINICUM. *Ed., Dub. Succinic Acid.*

"Take of Amber reduced to powder, and of Sand, *equal parts.* Mix them, and put the mixture in a glass retort, of such a size as to be only half filled by it. Then adapt a receiver, and distil, by means of a sand-bath, with a fire gradually increased. At first a watery liquor will come over, with a little yellow oil; then a yellow oil with an acid salt; and lastly, a reddish and black oil. Pour the liquor out of the receiver, and separate the oil from the water. Press the Succinic Acid, collected from the neck of the retort and sides of the receiver, between folds of blotting paper, to free it from adhering oil; then purify it by solution in warm water, and crystallization." *Ed.*

"Take of Amber reduced to coarse powder, and of pure Sand, each *one part.* On the application of heat gradually increased, an acid liquor, an oil, and the acid in the crystallized form will distil over. The latter should be received on bibulous paper, and exposed to a strong pressure to expel the oil, and again sublimed. By filtration through bibulous paper, the oil may be obtained separate from the acid liquor." *Dub.*

The above formulæ have for their object to obtain the oil of amber, as well as succinic acid; but our remarks will be confined in this place, to the acid, the oil being described under another head. (See *Oleum Succini.*) Amber contains succinic acid united with a peculiar oily matter. When distilled, it swells considerably, and a slightly coloured liquid first comes over; after which the succinic acid sublimes, and condenses in needles in the neck of the retort and on the sides of the receiver. At last the matter suddenly ceases to swell, and the process is finished; for after this time, very little succinic acid is disengaged, but a thick and dark coloured oil rises, which renders the acid impure. The Colleges direct the admixture of sand, to prevent the inconvenience of the amber swelling too much by the heat.

Several processes have been proposed to purify succinic acid. The best is that of Morveau, which consists in dissolving the acid in twice its weight of nitric acid, and evaporating the solution to dryness. In this way the oil is decomposed, while the succinic acid remains unaltered. This is then washed in a little ice-cold water, next dissolved in boiling water, and crystallized.

---

* For further information the reader is referred to the third volume of the Journ. of the Phil. College of Pharmacy, for a paper on nitromuriatic acid by Daniel B. Smith of Philadelphia, to whom we are indebted for the principal chemical facts and calculations contained in this article.

Properties. Succinic acid, when pure, is a white, transparent solid, crystallizing in prisms, and having a somewhat acrid taste. It reddens litmus strongly. Exposed to heat it melts, and above the boiling point of water is partly sublimed and partly decomposed. It dissolves in five times its weight of cold, and twice its weight of boiling water. It is soluble also in cold alcohol, and much more so in boiling alcohol. It consists of two equiv. of hydrogen 2, four of carbon 24.48, and three of oxygen 24=50.48. It differs, therefore, from acetic acid, only in containing one equiv. less of hydrogen.

Succinic acid is at present never used in medicine, and ought to be expunged from the Pharmacopœias. B.

ACIDUM SULPHURICUM AROMATICUM. *U. S.*, *Ed.*, *Dub.*

Aromatic Sulphuric Acid. Elixir of Vitriol.

"Take of Sulphuric Acid *three fluidounces and a half;* Ginger, bruised, *an ounce;* Cinnamon, bruised, *an ounce and a half;* Alcohol *two pints.* Drop the Acid gradually into the Alcohol, and digest in a close vessel for three days; then add the Ginger and Cinnamon, and macerate for a week; lastly, filter through paper." *U.S.*

"Take of Stronger Alcohol *two pounds* [Rectified Spirit *two pints*, *Dub.*]; Sulphuric Acid *six ounces.* Add the Acid gradually to the Alcohol. Digest the mixture with a very gentle heat, in a covered vessel, for three days, and then add Cinnamon Bark, bruised, *an ounce and a half;* Ginger Root, bruised, *an ounce.* Digest again in a covered vessel for six days, and then filter through paper placed in a glass funnel." *Ed.*

This valuable preparation, commonly called *elixir of vitriol*, is a simplification of the acid elixir of Mynsicht, and was adopted from the Edinburgh College, in the first United States Pharmacopœia, and afterwards by the Dublin College, in their revised edition of 1826. The only change in the Edinburgh formula, made by the United States Convention, is the substitution of the nearest equivalent measures for the weights of the liquid ingredients. In the Edinburgh directions, the acid is to the alcohol in weight as 1 to 4; in the United States Pharmacopœia (the measures being turned into weights), as 1 to 4.15, which is a sufficiently near coincidence for all practical purposes. The Dublin College has adopted the Edinburgh formula throughout, with the exception of substituting two pints of alcohol for two pounds; a change which renders the preparation considerably weaker in acid, as two pints of officinal alcohol weigh more than two pounds.

Properties. Aromatic sulphuric acid is a reddish-brown liquid, of a peculiar aromatic odour, and, when sufficiently diluted, of a grateful acid taste. It has been supposed by some to be a kind of ether, its main ingredients justifying such a suspicion; but the late Dr. Duncan, who originally held this opinion, satisfied himself that the alcohol and sulphuric acid, in the proportions here employed, do not produce a single particle of ether. It must, therefore, be viewed merely as sulphuric acid diluted with alcohol, and containing the essential oils of ginger and cinnamon.

Medical Properties and Uses. It is tonic and astringent, and affords the most agreeable mode of administering sulphuric acid. It is very much employed in debility with night sweats, in loss of appetite, and in the convalescence from fevers, especially those of the intermittent type. It is often given in conjunction with cinchona, the taste of which it serves to cover, and, by increasing the solubility of the febrifuge principles of the bark, appears to increase its efficacy. In hæmoptysis and other hemorrhages, when not attended with obvious inflammation, it frequently proves useful in stopping the flow of blood. The dose is from ten to thirty drops in a wineglassful of water, repeated two or three times a day. B.

ACIDUM SULPHURICUM DILUTUM. *U. S., Lond., Ed., Dub. Diluted Sulphuric Acid.*

"Take of Sulphuric Acid *a fluidounce;* Water *thirteen fluidounces.* Add the Acid gradually to the Water in a glass vessel, and mix them." *U.S.*

"Take of Sulphuric Acid *a fluidounce and a half;* Distilled Water *fourteen fluidounces and a half.* Add the Acid gradually to the Water, and mix them." *Lond.*

"Take of Sulphuric acid *one part;* Water *seven parts.* Mix them." *Ed.*

"Take of Pure Sulphuric Acid *one part;* Distilled Water *seven parts.* Gradually add the Acid to the Water. The specific gravity of this acid is 1.084." *Dub.*

This preparation is sulphuric acid diluted to such an extent as to make it convenient for medical use. The Edinburgh and Dublin Colleges agree in making the strong acid one-eighth part of the mixture; and in the U. States Pharmacopœia, these proportions are followed, as nearly as they can be approached in measures. The exact proportions of these Colleges, expressed in measures, would be 1 fluidounce of acid to 12.9 fluidounces of water, which is sufficiently near the proportion of 1 to 13, to justify the adoption of the latter numbers. There is accordingly a virtual agreement in the strength of the acid, by the three processes just mentioned; but unfortunately the formula of the London College gives an acid considerably stronger. The coincident processes afford an acid containing between 12 and 13 per cent. of the strong liquid acid; while the London acid contains 16 per cent. The strong acid is added gradually to the water, to guard against the too sudden production of heat, which might cause the fracture of the vessel. During the dilution, when commercial sulphuric acid is used, the liquid becomes slightly turbid, and in the course of a few days deposites a grayish-white powder, which is sulphate of lead, an impurity in the strong acid, not soluble in it after considerable dilution. This noxious salt is thus got rid of, but sulphate of potassa, another impurity in the strong acid, still remains in solution. To avoid these impurities, the Dublin College directs *pure* sulphuric acid and *distilled* water. This, however, would seem to be a useless refinement, as the sulphate of lead in the commercial acid is precipitated by dilution as above explained, and the presence of sulphate of potassa can do no harm.

Medical Properties and Uses. Diluted sulphuric acid is tonic, refrigerant, and astringent. It is given in low typhoid fevers, and often with advantage. In the convalescence from protracted fevers, it often acts beneficially as a tonic, exciting the appetite and promoting digestion. As an astringent, it is employed in colliquative sweats, passive hemorrhages, and diarrhœas dependent on a relaxed state of the mucous membrane of the intestines. Externally, it is used as an ingredient in gargles for ulcerated sore throat and for checking excessive ptyalism, and as a wash for cutaneous eruptions and ill-conditioned ulcers. The dose is from ten to thirty drops three times a day, in a wineglass or two of plain or sweetened water. It is added with advantage to infusions of cinchona, the organic alkalies of which it tends to hold in solution. As it is apt to injure the teeth, it is best taken by sucking it through a quill. It is much less used in the United States than the elixir of vitriol, which possesses nearly the same medical properties. (See *Acidum Sulphuricum* and *Acidum Sulphuricum Aromaticum.*)

This acid is employed as a chemical agent for preparing the benzoic and citric acids, and the precipitated sulphuret of antimony.

Off. Prep. Infusum Rosæ Compositum, *U.S.*, *Lond.*, *Ed.*, *Dub.;* Morphiæ Sulphas, *U.S.;* Quininæ Sulphas, *Dub.;* Solutio Sulphatis Zinci, *Ed.* B.

ACIDUM SULPHURICUM PURUM. *Dub.* *Pure Sulphuric Acid.*

"Take of Commercial Sulphuric Acid *a pound.* Put the acid into a retort of flint glass, attach a receiver of the same kind, and with the junctures of the vessels left open, let heat be applied to the retort until one-twelfth part of the liquor shall have distilled over: this, as it contains water, should be rejected. The receiver being again applied, the residuum is to be distilled to dryness. A few slips of platinum put into the acid in the retort, will restrain the ebullition, which otherwise would be too violent. The specific gravity of this acid is 1.845. Let the acid be kept in well closed vessels." *Dub.*

The object of this process is to obtain a pure sulphuric acid. The commercial acid contains the sulphates of lead and potassa, amounting not unfrequently to three or four per cent.; and these salts, not being volatile, are effectually got rid of by distillation. The explanation of the several steps of the process for distilling this acid has been given under the head of *Acidum Sulphuricum*, p. 43, and need not be repeated here.

This preparation is peculiar to the Dublin College, and has been adopted in the late revision of their Pharmacopœia, to avoid the risk of introducing sulphate of lead into the preparations of sulphuric acid. But this acid is never used in a concentrated form; and in the dilute state in which it is employed, it always lets fall this metallic salt. Admitting, however, that there is some danger of metallic impurity from using the commercial acid, the Dublin College have committed the double error of omitting to use their pure acid, where on their principles it is necessary, and of employing it in formulæ in which it is not needed. The only officinal preparation of the *pure* acid is the *Acidum Sulphuricum Dilutum;* but it would seem equally required in the elixir of vitriol, where the commercial acid may be considered as directed. On the other hand, the diluted sulphuric acid is employed uselessly in the processes for citric acid and the precipitated sulphuret of antimony, where it acts merely as a chemical agent.

Off. Prep. Acidum Sulphuricum Dilutum. *Dub.* B.

* * *

ÆTHEREA.

Ethers.

Ethers are peculiar, fragrant, sweetish, very volatile, and inflammable liquids, generated by the action of acids on alcohol. Their composition varies with the acid employed in their formation. Sometimes this merely acts on the alcohol as a chemical agent, without entering into the composition of the ether generated; in which case the ether consists of water and etherine. In other instances the acid employed unites with water and etherine (the ether just mentioned), or with etherine simply. On the basis of these differences of composition, ethers are divided into three kinds:

1. those consisting of water and etherine; 2. those consisting of an acid, water, and etherine; and 3. those composed of an acid and etherine only. Sulphuric ether is an example of the first kind, nitric ether of the second, and muriatic ether of the third. In medicine, the sulphuric and nitric ethers, and their modifications, are those most commonly employed; though occasionally the acetic and muriatic have been used.

Ethers, from their extreme inflammability, ought never to be decanted in the vicinity of flame. Hence it is prudent not to pour them out near a lighted candle. They should be kept in accurately stopped bottles in a cool place; otherwise they are liable to considerable loss by evaporation. B.

ÆTHER SULPHURICUS. *U. S., Lond.* LIQUOR ÆTHEREUS SULPHURICUS. *Dub.* *Unrectified Sulphuric Ether.*

"Take of Alcohol *two pounds and a half;* Sulphuric Acid *a pound and a half.* Pour a pound and a half of the Alcohol into a glass retort, and gradually add the Acid, shaking them frequently, and taking care that the temperature, during the mixture, do not exceed one hundred and twenty degrees. Place the retort very cautiously in a sand-bath, previously heated to two hundred degrees, so that the liquor may boil as speedily as possible, and the ether may pass over into a tubulated receiver, to which another receiver, kept cold by ice or water, is adapted. Distil the liquor until a heavier portion begins to pass over, and appears under the ether at the bottom of the receiver. To the liquor which remains in the retort, add the residue of the Alcohol, and repeat the distillation in the same manner." *U.S.*

The process of the *London* College is essentially the same with the above, which was copied from it, with slight alterations of phraseology to adapt it to the plan of the United States Pharmacopœia.

"Take of Rectified Spirit and of Sulphuric Acid, each, *thirty-two ounces by weight.* Pour the Spirit into a glass retort adapted to bearing a sudden heat, and then pour on the acid in a continued stream; mix them gradually, and let twenty fluidounces of the liquor be distilled, with a sudden and sufficiently strong heat, into a receiver kept cold. If *sixteen ounces* of rectified spirit be poured upon the acid remaining in the retort, sulphuric ethereal liquor will again come over by distillation." *Dub.*

The preparation obtained by these processes is sulphuric ether contaminated with alcohol, water, sulphurous acid, and the oil of wine. In this state it is proper only for external use. For internal exhibition it is freed from these impurities, and then becomes a distinct preparation, called Rectified Sulphuric Ether. This is described in the next article, in which the properties and composition of sulphuric ether, and the theory of its formation will be given.

Off. Prep. Æther Sulphuricus Rectificatus, *U.S., Lond., Ed. Dub.* B.

ÆTHER SULPHURICUS RECTIFICATUS. *U.S.* ÆTHER RECTIFICATUS. *Lond.* ÆTHER SULPHURICUS. *Ed., Dub.* *Rectified Sulphuric Ether.*

"Take of Sulphuric Ether *fourteen fluidounces;* Potassa *half an ounce;* Distilled Water *eleven fluidounces.* Dissolve the Potassa in two fluidounces of the Water, and add the Ether to the solution, shaking them well till they are mixed; then, at a heat of about one hundred and twenty degrees, distil from a large retort into a cooled receiver twelve fluidounces of Rectified Ether. Shake the distilled liquor with nine fluidounces of the Water, and set them by that the Water may subside. Lastly, pour off the supernatant Rectified Ether, and preserve it in a well stopped bottle." *U.S.*, *Lond.*

"Take of Sulphuric Acid, and of Stronger Alcohol [Rectified Spirit], each, *thirty-two ounces*. Pour the Alcohol into a glass retort capable of sustaining a sudden heat, and add to it the acid in an uninterrupted stream. Mix them by degrees, shaking them gently and frequently, and instantly distil from sand, previously heated for the purpose, into a receiver kept cool with water or snow. The heat must likewise be so managed, that the liquor shall boil as soon as possible, and continue to boil till sixteen ounces are drawn off, when the retort is to be removed from the sand. To the distilled liquor add two drachms of potassa, and distil from a very high retort, with a very gentle heat, into a cool receiver, until ten ounces have been drawn off. If *sixteen ounces* of Stronger Alcohol be poured upon the acid remaining in the retort after the first distillation, and the distillation be repeated, more ether will be obtained; and this may be repeated several times." *Ed.*

"Take of Sulphuric Ethereal Liquor *twenty fluidounces*; Carbonate of Potassa, dried and powdered, *two drachms*. Mix them, and from a very high retort, distil, by a very gentle heat, twelve fluidounces into a receiver kept cold. The specific gravity of the liquor is 0.765." *Dub.*

The object of these processes is to obtain a pure sulphuric ether. The first and third formulæ are intended to purify the unrectified sulphuric ether, which is officinal only in the United States, London, and Dublin Pharmacopœias. The second, or Edinburgh process, forms and purifies the ether at one operation. Hence the Edinburgh Pharmacopœia has no preparation corresponding to the unrectified ether of the other Pharmacopœias. By an unfortunate confusion in nomenclature, the title "*Æther Sulphuricus*" means unrectified ether in the United States and London Pharmacopœias, and rectified in those of Edinburgh and Dublin.

The generation and rectification of sulphuric ether, may be considered as different steps of one chemical operation; and are, therefore, most conveniently treated of under the same head. In the process for preparing it, the acid is gradually added to the alcohol to prevent too great a heat, which would generate a portion of ether before the arrangements are completed for collecting it. After the receivers have been attached, and the junctures luted, the retort is placed in a sand-bath, previously heated to 200°, for the purpose of forming the ether quickly; for if the retort were gradually heated, the greater part of the alcohol would distil over, without being converted into ether, and the process would furnish a comparatively small product. The lutings are best made with common paste, spread on strips of muslin, which are first applied, and afterwards, when dry, covered over with slips of moistened bladder. The receiver is refrigerated on account of the great volatility of ether, a part of which, without this precaution, would be lost. A convenient mode for keeping the receivers cold is to lay across them a number of strips of woollen cloth, one end of which is immersed in cold water placed higher than the receivers. By this arrangement, cold water is made continually to trickle over them, whereby they are kept cool; and at the same time the progress of the distillation may be seen, which is not the case when they are immersed in water. The moment when the heavier portion begins to pass over, which is the signal for discontinuing the process, is indicated by the appearance of white vapours in the retort. If the distillation were continued after this, very little ether would be obtained; but there would be generated, sulphurous acid, oil of wine, olefiant gas, carbonic acid, and a large quantity of carbonaceous matter, blackening and rendering thick the residuary liquid.

The above remarks apply to the formula of the U.S. and Lond. Pharmacopœias. The processes of the Edinburgh and Dublin Colleges are in principle the same, and do not require a separate explanation. In repeating the London (U.S.) process, Mr. Phillips obtained twelve fluidounces of product, six fluidrachms of which were the heavy liquid mentioned in the formula, and the remainder the officinal Æther Sulphuricus of sp. gr. 0.768. Upon adding the second portion of alcohol, the quantity of ether produced was nearly similar, but its sp. gr. was as high as 0.807. The process for forming ether, however, is most advantageously performed on a large scale. At Apothecaries' Hall, where the operation is conducted in this way in a cast iron still lined with lead, Mr. Brande informs us that 100 pounds of sulphuric acid and of alcohol are taken, and afford about 52 pounds of ether of the sp. gr. 0.761. Fifty pounds of alcohol are then added to the residue, and upon a second distillation, from 46 to 50 additional pounds of ether are drawn off, having the sp. gr. 0.765. About 100 pounds of impure ether are thus obtained, which, when purified, yield from 55 to 58 pounds of rectified ether of the sp. gr. 0.733. The mixture of acid and alcohol is heated by means of steam, passing through a contorted leaden pipe at the bottom of the still, and supplied by a boiler, situated in an adjoining apartment, and capable of bearing a pressure of 100 pounds to the square inch. Mr. Brande states that if the attempt be made to generate the ether at the temperature of 212° or even 220°, little else than alcohol will pass over. According to this chemist a temperature of from 250° to 280° is required.

The rectification of ether is intended to purify it from sulphurous acid, oil of wine, and alcohol, and is variously conducted according to the different Pharmacopœias. The distillation with a gentle heat from potassa has the effect of separating the sulphurous acid and oil of wine, and the greater part of the alcohol. The remainder of the alcohol passes over with the ether, and is afterwards separated in the United Ststes and London processes by agitation with water. This liquid having a stronger affinity than ether for alcohol, unites with the latter, and forms a combination which sinks, while the pure ether floats above it. The Edinburgh College adds the potassa to the impure ether in the solid state, which is preferable to dissolving it previously in water. This College omits the subsequent agitation with water to separate alcohol, probably because in the distillation so small a portion is drawn off (ten ounces only from sixteen). The Dublin College performs the rectification by a distillation from carbonate of potassa, twelve parts only in twenty being drawn off. This salt is usually employed by the manufacturing chemist, the distillation being continued so long as the ether comes over of a sufficiently low specific gravity.

Properties. Rectified sulphuric ether is a colourless very limpid liquid; of a strong and sweet odour, and hot pungent taste. When as pure as possible, its sp. gr. is about 0.700; but the ether used in medicine is never of so high a strength. The Dublin College directs that rectified ether shall have the sp. gr. 0.765; the United States, London, and Edinburgh Pharmacopœias have omitted to designate the specific gravity of this preparation. Its sp. gr. as obtained at Apothecaries' Hall, London, is 0.733; as directed by the Paris Codex, 0.758. For medicinal purposes, its specific gravity should not be higher than 0.750. It is a very volatile liquid, and when of the sp. gr. 0.720, boils at about the temperature of 98°, and forms a vapour which has the density of 2.5817. Its extreme volatility causes it to evaporate speedily in the open air, with the production of a considerable degree of cold. Its inflammability is very great, and the products of its combustion are water and carbonic acid. In consequence of this property, the greatest caution should be used not to bring it too near a burning body, as for example, a lighted candle, for fear of its accidental inflammation. When too long kept, it undergoes decomposition, and becomes converted in part into acetic acid. Phosphorus and sulphur are slightly soluble in it, and the former is generally exhibited in ether ealsolution. (See *Phosphorus* in the Appendix.) Water dissolves a tenth of its weight of ether, and reciprocally ether takes up a small portion of water. It unites in all proportions with alcohol.

Composition, and Theory of its Production. Sulphuric ether consists, in ultimate constituents, of five equiv. of hydrogen 5, four of carbon 24.48, and one of oxygen 8=37.48; or in volumes, of five volumes of hydrogen, four volumes of the vapour of carbon, and half a volume of oxygen, condensed into one volume of ether vapour. Its proximate constituents are one equiv. of etherine 28.48, and one equiv. of water 9=37.48; or in volumes, one volume of etherine, and one volume of the vapour of water, condensed into one volume. The sp. gr. of its vapour, calculated on this composition in volume, is 2.5817, which is very near 2.586, the number obtained by experiment. By this statement of the composition of *sulphuric* ether, it is perceived that it contains no *sulphuric* acid, contrary to what its name would seem to indicate. The fact is, that it is called *sulphuric* ether, merely in allusion to the agency of the acid usually employed in its preparation; but an identical ether may be obtained by the action of other acids on alcohol. The French chemists, in allusion to the water which it contains, sometimes call it *hydric ether.*

With a view to determine in what manner sulphuric acid acts upon alcohol in order to convert it into ether, it is necessary that a comparison should be instituted between the composition of the two latter. It has already been stated under *Alcohol*, p. 57, that this liquid, according to modern views, consists of one equiv. of etherine and two equiv. of water; and ether, as just mentioned, is composed of one equiv. of etherine and one equiv. of water. It thus appears that alcohol to be converted into ether, only requires to lose one equiv. of water, that is, half the water present in it. On this view, then, the theory of etherification consists in the abstraction from alcohol of half the essential water which it contains. The agent in effecting this abstraction is evidently the sulphuric acid, which is known to have a strong affinity for water. If the original proportions of acid and alcohol continued the same throughout the whole of the distillation, all the alcohol would be resolved into water and ether; but, during the progress of the process, the alcohol is constantly diminishing, and of course the relative excess of the acid becoming greater; and at last a point of time arrives when the excess of acid is so great that the generation of ether ceases. As these results depend upon the relative deficiency of the alcohol, while the acid remains but slightly changed in amount, it is easy to understand why a second distillation may be practised, as prescribed in the Pharmacopœias, by adding a fresh portion of alcohol to the residue in the retort; for by this addition, the proper relative proportion of the alcohol to the acid is restored. But the repetition of the distillation in this manner has its limit; as the acid becomes at last too dilute to react upon the alcohol.

Medical Properties and Uses. Ether is a powerful diffusible stimulant, though transient in its operation. It is also esteemed antispasmodic and narcotic. Its vapour when breathed from a bladder in which a few teaspoonfuls have been put, produces a transient intoxication, resembling the effects of respiring nitrous oxide, but very dangerous if carried too far. In some stages of low fevers, attended with subsultus tendinum, ether sometimes proves useful as a stimulant and antispasmodic. It is useful also in nervous headach unattended with vascular fulness, some states of hysteria, and generally in nervous and painful diseases which are unaccompanied by inflammation. In catarrhal dyspnœa, and spasmodic asthma, its vapour may be inhaled with advantage by holding in the mouth a piece of sugar, to which a few drops of ether have been previously added. In nausea it is given as a cordial, and in flatulence of the stomach it sometimes acts with singular efficacy. According to Mr. Brande, a small teaspoonful of ether mixed with a glass of white wine, is often a most effectual remedy for allaying the distressing symptoms of sea-sickness. When externally applied it may act either as a stimulant or refrigerant. If its evaporation be repressed, it operates as a powerful rubefacient, and may even vesicate; but when its evaporation is allowed to take place freely, it is refrigerant in consequence of the great degree of cold which it produces. In the latter way it is sometimes employed in strangulated hernia. Dr. A. T. Thomson has found ether sometimes to produce immediate relief when dropped in the ear in earach. For external use, the unrectified ether may be employed. The dose of rectified ether is from half a fluidrachm to two fluidrachms, to be repeated frequently when the full effect of the remedy is desired. It may be perfectly incorporated with water or any aqueous mixture, by rubbing it up with spermaceti, employed in the proportion of two grains for each fluidrachm of the ether. The ether and spermaceti are to be rubbed together in a mortar, until the latter is perfectly dissolved; and to the solution thus formed the water or mixture is to be added, while the whole is constantly stirred. The incorporation being finished, the operation is completed by passing the mixture through a piece of muslin to separate the spermaceti. (Durand, *Journ. of the Phil. Col. of Pharm.* iv. 202.)

Off. Prep. Spiritus Ætheris Sulphurici, *U. S.*, *Lond.*, *Ed.* B.

OLEUM ÆTHEREUM. *U.S.*, *Lond.* LIQUOR ÆTHEREUS OLEOSUS. *Dub.* *Ethereal Oil.* *Oil of Wine.*

"After the distillation of Sulphuric Ether, carry on the distillation with a less degree of heat, until a black froth begins to rise; then immediately remove the retort from the fire. Add water to the liquor in the retort, that the oily part may float upon the surface. Separate this and add to it sufficient Lime-water to neutralize the acid present, and shake them together. Lastly, when the oil has separated, remove it." *U.S.*, *Lond.*

"Take what remains in the retort, after the distillation of Sulphuric Ether. Distil down to one half, with a moderate heat." *Dub.*

Towards the end of the distillation of Rectified Sulphuric Ether, there is formed a small quantity of a peculiar oleaginous matter, usually called *oil of wine.* This matter is the officinal ethereal oil, the object of the above processes. The formation of this oil is connected with complicated changes, which are not well understood. It appears that during the reaction which takes place between sulphuric acid and alcohol in the process for making ether, two compounds of etherine with sulphuric acid are formed; one a bisulphate of etherine with two equiv. of water, called *sulphovinic acid*; the other a neutral sulphate, consisting of two equiv. of acid and two of etherine, with one equiv. of water, which is the officinal *ethereal oil*, or *heavy oil of wine.* As etherine with two equiv. of water constitutes alcohol, it follows that sulphovinic acid may be viewed as a bisulphate of alcohol. For a description of etherine, see page 57.

Sulphovinic acid combines with bases, forming salts called sulphovinates, which may be viewed as double sulphates of etherine and the added base. When a sulphovinate, as for example the sulphovinate of lime, is heated in a retort, furnished with a receiver, sulphate of lime is left behind, while a portion of the sulphate of etherine, or heavy oil of wine, distils over unchanged. If this, after being purified, be heated in a matrass with a long neck, covered with a stratum of water, it will entirely disappear, being resolved into sulphovinic acid which will dissolve in the water, and a light oily matter which will float on its surface. This oily matter consists of a liquid and a solid principle, separable from each other by the application of a freezing temperature; the former being called the *light*, the latter, the *concrete oil of wine.* Thus chemists recognise at present three oils of wine,—the *heavy* or sulphate of etherine, the *light*, and the *concrete.* The first, or the officinal oil, alone contains sulphuric acid; the other two are isomeric with etherine, and devoid of this acid.

The officinal oil of wine is not easily obtained. The U. S. process, which is adopted from the London, furnishes but a small amount of it, and is difficult of execution. An easier way of obtaining it is to distil the sulphovinate of lime (the double sulphate of lime and etherine); when the officinal oil of wine (sulphate of etherine) will come over. It is best purified from alcohol and ether by washing it with water, and from water and sulphurous acid by exposure to the action of sulphuric acid under an exhausted receiver. The Dublin formula is altogether defective. By distilling the residue of the sulphuric ether process "down to one half with a moderate heat," the oil of wine is no doubt generated; but it is mixed with various substances, from which no directions are given in the formula for its separation.

Properties. The *officinal ethereal oil* is green or colourless, and possesses an oleaginous consistency, an aromatic odour, and a pungent taste. Its sp. gr. is 1.133. Sparingly soluble in water, it is very soluble in alcohol and ether. Though containing sulphuric acid, it has no acid reaction, its acid being completely neutralized by the etherine with which it is united. The *light oil of wine* has a slightly yellow colour, and an aromatic odour, which is developed by rubbing it between the fingers. It communicates a greasy stain to paper. Its density at 51° is 0.917, and its boiling point very high. The *concrete oil* crystallizes in long transparent and brilliant prisms. It has no taste, and a smell like that of the light oil. Its density is 0.960. It melts at 230°, and volatilizes without change at 500°. It is insoluble in water, but soluble in alcohol and ether.

The officinal oil is not used in medicine in a separate state, but enters into the composition of the compound spirit of sulphuric ether, or Hoffmann's anodyne.

Off. Prep. Spiritus Ætheris Sulphurici Compositus, *U.S.*, *Lond.* B.

SPIRITUS ÆTHERIS SULPHURICI. *U.S.*, *Lond.* ÆTHER SULPHURICUS CUM ALCOHOLE. *Ed.* *Spirit of Sulphuric Ether.*

"Take of Rectified Sulphuric Ether *half a pint;* Alcohol *a pint.* Mix them." *U.S.*, *Lond.*

"Take of Sulphuric Ether *one part;* Stronger Alcohol *two parts.* Mix them." *Ed.*

This preparation is merely rectified ether diluted with twice its volume or weight of alcohol. When prepared with materials of proper strength, its sp. gr. is 0.816. Its medical properties are similar to those of ether. Its dose is from one to three fluidrachms, given with a sufficient quantity of water. B.

SPIRITUS ÆTHERIS SULPHURICI COMPOSITUS. *U.S., Lond. Compound Spirit of Sulphuric Ether. Hoffmann's Anodyne Liquor.*

"Take of Spirit of Sulphuric Ether *a pint;* Ethereal oil *two fluidrachms.* Mix them." *U.S., Lond.*

This preparation is intended as a substitute for the anodyne liquor of Hoffmann, which it closely resembles. In addition to the stimulating and antispasmodic qualities of the ether which it contains, it possesses anodyne properties, highly useful in nervous irritation, and want of sleep arising from this cause. These additional virtues it derives from the officinal or heavy oil of wine, which is a more important substance than is generally admitted. Mr. Brande asserts that the only effect of it in the preparation under notice, is to alter the flavour of the Spirit of Sulphuric Ether. In this assertion he is certainly in error. Dr. Hare, in his Chemical Compendium, reports the opinion of Drs. Physick and Dewees, in favour of the efficacy of the officinal oil of wine, dissolved in alcohol, in certain disturbed states of the system as a tranquillizing and anodyne remedy. Such indeed are the generally admitted effects of Hoffmann's anodyne, when made with a due admixture of the ethereal oil; but the Spirit of Sulphuric Ether is often improperly sold for it. When properly prepared, it becomes milky on being mixed with water, in consequence of the precipitation of the oil. It is on many occasions a useful adjunct to laudanum, to prevent the nausea which is liable to be excited by the latter in certain habits. Its dose is from half a fluidrachm to two fluidrachms in any proper vehicle. B.

SPIRITUS ÆTHERIS AROMATICUS. *Lond.* ÆTHER SULPHURICUS CUM ALCOHOLE AROMATICUS. *Ed. Aromatic Spirit of Ether.*

"Take of Cinnamon Bark, bruised, *three drachms;* Cardamom Seeds, in powder, *a drachm and a half;* Long Pepper, in powder, Ginger Root, sliced, each, *a drachm;* Spirit of Sulphuric Ether *a pint.* Macerate for fourteen days in a well stopped glass bottle, and filter." *Lond.*

"Take of Cinnamon Bark, bruised, Lesser Cardamom Seeds, bruised, each, *an ounce;* Long Pepper, in powder, *two drachms;* Sulphuric Ether with Alcohol, *two pounds and a half.* Digest for seven days, and filter through paper." *Ed.*

This is merely the Spirit of Sulphuric Ether, rendered more grateful by aromatics. The difference between the two formulæ for its preparation is not important; but we should prefer the London. Its medical properties and dose are the same as those of the preparation which forms its basis. It is very rarely if ever prescribed. B.

ÆTHER NITROSUS. *Dub. Nitrous Ether (Nitric Ether).*

"Take of Purified Nitrate of Potassa, dried, and coarsely powdered, *a pound and a half;* Sulphuric Acid *a pound;* Rectified Spirit *nineteen fluidounces.* Put the Nitrate of Potassa into a tubulated retort, placed in a bath of cold water, and pour on it, by degrees and at intervals, the Sulphuric Acid and Spirit, previously mixed, and cooled after their mixture. Without almost any external heat, or at most a very gentle one, (as of warm water added to the bath,) the ethereal liquor will begin to distil without the application of fire. In a short time, the heat of the retort will increase spontaneously, and a considerable ebullition will take place, which must be moderated by reducing the temperature of the bath with cold water. The receiver must also be kept cold with water or snow, and furnished with a proper apparatus for transmitting the highly elastic vapour (bursting from the mixture with great violence if the heat be too much increased) through a pound of Rectified Spirit contained in a cooled bottle.

"The ethereal liquor thus spontaneously distilled, is to be received into a phial with a ground glass stopper; and then must be added by degrees (closing the phial after each addition) as much very dry and powdered carbonate of potassa as will suffice to saturate the excess of acid, using litmus as the test. This is effected by the addition of about a drachm of the salt. In a short time the Nitrous Ether will rise to the surface, and is to be separated by means of a funnel.

"If the Ether be required very pure, distil it again to one-half, from a water-bath at a temperature of 140°. Its specific gravity is 0.900." *Dub.*

The Dublin is the only Pharmacopœia commented on in this work, which embraces nitrous (nitric) ether among its preparations. The mutual reaction of nitric acid and alcohol is so violent, that the formation of this ether has justly been regarded as a process of difficulty. The method adopted by the Dublin College, in their formula, was contrived by Wolfe, and is commended by Pelletier, as well adapted for obtaining this ether with facility and safety. The alcohol is not mixed directly with nitric acid, but with the materials necessary for generating it. Upon the addition of the mixture of sulphuric acid and alcohol to the nitre, this salt is decomposed, and the disengaged nitric acid gradually reacts upon the alcohol, and generates the ether in question. The saline residue in the retort is sulphate of potassa. The heat evolved upon mixing the materials is so considerable, that the application of extraneous heat becomes unnecessary, and even hazardous. Indeed, as the action advances, the temperature of the mixture must be moderated by the application of cold water. The violent action arises from the vast quantity of gases and vapours suddenly given off. These are nitrogen, nitrous and nitric oxide, carbonic acid, and the vapours of water, nitrous acid, and of the nitric ether itself. Notwithstanding the cold employed, a portion of the nitric ether escapes condensation in the receiver, and hence the Dublin College, to save this portion, directs a cooled bottle to be connected with it, containing a pound of alcohol, into which the uncondensed ether is allowed to pass. The alcohol thus impregnated is subsequently employed in the Dublin formula for sweet spirit of nitre. (See *Spiritus Ætheris Nitrici.*) The ether condensed in the receiver is not pure, but contains a little nitrous, nitric, and acetic acids. To remove these, the ethereal product is shaken with carbonate of potassa, which has the effect of saturating them.

Nitric ether is prepared by Thenard according to the following process, which is adopted, with slight modifications, in the Paris Codex. Equal weights of alcohol and nitric acid, contained in a retort having a capacity double their volume, are distilled by a moderate heat, into a Wolfe's apparatus of five bottles, the first of which is empty, and the four others half filled with saturated brine. Each bottle is placed in an earthen pan containing a mixture of ice and salt. The apparatus being thus arranged, a few live coals are placed under the retort, whereupon the liquid enters quickly into ebullition. The fire must then be immediately withdrawn, and the ebullition moderated, by allowing some water pressed from a sponge to flow over the retort. The process is terminated when the spontaneous ebullition ceases; at which time the liquid in the retort forms a little more than a third of the quantity of alcohol and acid employed. In the first bottle, a large quantity of yellow liquid will be found, consisting of much weak alcohol, o ether, and nitrous, nitric, and acetic acids; in the second, a pretty thick stratum of ether, containing a little acid and alcohol, and swimming on the surface of the brine; in the third, a very thin stratum, of the same nature as tha in the second, and so on for the rest. The several layers of ether are then separated by means of a funnel, mixed together, and redistilled by a moderate heat, into a refrigerated receiver. The first product is the ether, which, to be perfectly pure, and devoid of acidity, must be allowed to remain in a bottle for half an hour, in contact with powdered lime. From 500 parts of alcohol, and 500 of acid, Thenard obtained 100 of excellent ether.

Dr. Hare has contrived an apparatus for generating nitric ether, which answers very well. It consists of a three-necked bottle, the outer orifices of which are furnished with glass funnels with stop-cocks; of a glass tube three feet long; and of a tubulated receiver, surrounded with a freezing mixture. The tube is arranged in an inclined position, and surrounded also by a freezing mixture contained in a wooden trough, and is so bent at its extremities, that the upper end may be attached to the middle neck of the bottle, and the lower to the receiver. The apparatus being thus arranged, alcohol is added to the bottle, through one of the funnels, to the depth of half an inch, and afterwards nitric acid is cautiously introduced through the other funnel, sufficient to cause an active ebullition. When this relaxes, more acid is added, and so on at intervals until the ebullition ceases to be renewed. When this happens, the alcohol is again added at intervals, until it ceases to excite any action in the materials, when the process is finished. The ether generated is effectually condensed by the frigorific mixture, and is collected in the receiver.

Dr. Duncan states in his Dispensatory, that he has "repeatedly prepared nitric ether with great facility and safety, by putting alcohol into a tubulated retort having a small long-tubed funnel introduced through a cork in the tubulature, so that the end of the funnel was immersed in the alcohol, pouring nitrous acid through this slowly, until reaction commenced, and waiting till it ceased before more acid was added in successive portions, until the whole proportion intended was added. After the spontaneous action had ceased, heat was cautiously applied as long as ether was produced." To condense the products, a Wolfe's apparatus was used, kept very cold. The first bottle was empty, and in it the principal part of the ether condensed; the second contained water, and the third alcohol. From this last a tube proceeded to give exit to the gases. This method of Dr. Duncan is probably a good one, and has the merit of being easily executed.

Properties. Nitrous or nitric ether as it is variously called, is a yellowish-white liquid, of an acrid and burning taste, and a smell resembling that of sulphuric ether, but much stronger. When simply washed with water, Dr. Duncan found its sp. gr. to be 0.912; but in this state it contained acid. When this was removed, its density became 0.896, and when rectified by a new distillation it fell to 0.866. The Dublin College and the Paris Codex direct its sp. gr. to be 0.900. This ether, therefore, is much heavier than the sulphuric, and even heavier than alcohol. When agitated with water it is divided into three portions; a small portion dissolves, a second evaporates, and a third is decomposed. The aqueous solution becomes immediately acid, and acquires the smell of apples. Nitric ether is soluble in all proportions in alcohol; and with a variable portion of the latter forms the spirit of nitric ether, or sweet spirit of nitre. It is more volatile than sulphuric ether, entering into ebullition at 70°. It is highly inflammable, and burns with a white flame, without residue. It is very liable to spontaneous decomposition, becoming acid after the lapse of a few days. It should be kept in full bottles in a dark cool place, and prepared in small quantities at a time.

Composition. Nitric ether consists of one equiv. of hyponitrous acid

38.15, and one equiv. of ether 37.48=75.63. Admitting this composition to be correct, its proper name would be *hyponitrous ether*.

Medical Properties and Uses. Nitric ether is seldom used in medicine. Its medical virtues are probably the same as those of sulphuric ether. B.

SPIRITUS ÆTHERIS NITRICI. *U.S., Lond.* Spiritus Ætheris Nitrosi. *Ed.* Spiritus Æthereus Nitrosus. *Dub.* *Spirit of Nitric Ether. Sweet Spirit of Nitre.*

"Take of Nitrate of Potassa, in powder, *two pounds;* Sulphuric Acid *a pound and a half;* Alcohol *nine pints and a half;* Diluted Alcohol *a pint;* Carbonate of Potassa *an ounce.* Mix the Nitrate of Potassa and the Acid in a glass retort, and, having gradually poured in the Alcohol, digest with a gentle heat for two hours; then raise the heat, and distil a gallon. To the distilled liquor add the Diluted Alcohol and Carbonate of Potassa, and again distil a gallon." *U.S.*

"Take of Rectified Spirit *two pints;* Nitric acid, by weight, *three ounces.* Add the Acid to the Spirit by slow degrees, and mix them, taking care that the temperature does not exceed one hundred and twenty degrees; then, by means of a gentle heat, distil twenty-four fluidounces." *Lond.*

"Take of Stronger Alcohol [Rectified Spirit] *three pounds;* Nitrous Acid *a pound.* Pour the Alcohol into a capacious phial, placed in a vessel full of cold water, and add the Acid by degrees, constantly agitating them. Let the phial be slightly covered, and placed for seven days in a cool place; then distil the liquor with the heat of boiling water, into a receiver kept cool with water or snow, until about three pounds come over." *Ed.*

"Add to the matter which remains after the distillation of Nitrous Ether, the Rectified Spirit employed in that operation for condensing the elastic vapour, and distil till the residuum be dry, with the *superior* heat of a water-bath. Mix the distilled liquor with the alkaline liquor which remains after the separation of the Nitrous Ether, and add, moreover, as much well dried Carbonate of Potassa as shall be sufficient to saturate the predominant acid. This is made evident by the test of litmus. Lastly, distil as long as any drops come over by the *medium* heat of a water bath. The specific gravity of this liquor is 0.850.

"Nitrous Ethereal Spirit may also be prepared by adding gradually *two ounces* of Nitric Acid to *a pint* of Rectified Spirit, and distilling twelve ounces with a proper apparatus and the application of a gentle heat." *Dub.*

The Spirit of Nitric Ether is a mixture, in variable proportions, of nitric ether and alcohol. Nitric ether is always generated by the mutual reaction of nitric acid and alcohol; and it matters not whether the alcohol be mixed with nitric acid directly, or with the materials for generating it, namely, nitre and sulphuric acid. When the materials for forming the ether contain an excess of alcohol, this distils over with the ether, and forms the preparation under consideration.

The processes given above differ considerably. The U.S. and Dublin Pharmacopœias obtain the requisite nitric acid by using the materials for generating that acid; while the London and Edinburgh Colleges mix the acid ready formed with the alcohol. The different formulæ will be noticed in the order just named.

The U.S. formula is modeled after a recipe communicated by Mr. John Carter, manufacturing chemist, to the Philadelphia College of Pharmacy, and recommended for adoption by a committee of that body. It is in fact the Dublin process for obtaining nitric ether, explained in the preceding article, with the use of alcohol in excess. The nitre and sulphuric acid being placed in the retort, the materials are ready for generating the nitric acid. The alcohol being gradually added, and a gentle heat applied, the nitric acid is set free, and by reacting on a part of the alcohol produces the ether. Upon the subsequent increase of the heat, this ether and the remainder of the alcohol distil over as the spirit of nitric ether. The distilled product, however, contains some acid, and hence is rectified by a distillation from carbonate of potassa. The diluted alcohol is added before commencing this distillation, to enable the operator to obtain a quantity of distilled product equal to that procured at first, without distilling to dryness, which would endanger the production of empyreuma. The sulphuric acid and alcohol are added successively to the nitre, and not previously mixed; as by the latter plan, the sulphuric acid would be converted in part into sulphovinic acid, and the risk would be run of generating some sulphuric ether. The retort should be of such a capacity as to be capable of holding twice the amount of the materials employed. It would be an improvement in this formula, if the nitre were directed to be bruised, rather than powdered; as the more slowly the nitric acid is liberated, the more safely the process may be conducted.

The above process, as conducted by Mr. Carter on a large scale, is performed in a copper still of about twenty gallons capacity, and furnished with a pewter head and worm. The materials for the first distillation are 18 pounds of purified nitre, 12 gallons of alcohol of 34° Baumé (0.847), and 12 pounds of sulphuric acid; and 10 gallons are drawn off. The distilled product is then mixed with a gallon of diluted alcohol, and rectified by a new distillation from lime or a carbonated alkali; the same quantity being distilled as at first. When large quantities of this preparation are thus obtained, the several portions require to be mixed in a large glass vessel, to render the whole of uniform strength; as the portion which first comes over in the rectification is strongest in nitric ether. Previous to the redistillation, the head and worm must be washed thoroughly with water, to remove a little acid which comes over in the first distillation. (*Journ. of the Phil. Col. of Pharm.* i. 308.)

A similar process to the above for making sweet spirit of nitre, is adopted in the principal laboratories of Philadelphia. As the use of metallic vessels is attended with some risk, it would be an improvement in the above process, if an earthenware still and worm were employed, as is done at Apothecaries' Hall, London; the still being heated by the slow application of steam to its outer surface.

In order to understand the process of the Dublin College for preparing sweet spirit of nitre, it will be necessary to revert to their formula for obtaining nitric ether, and the explanations connected with it. The residue of the latter process consists of sulphate of potassa, free nitric acid not consumed in the generation of the nitric ether, and, perhaps, a portion of alcohol. To this residue is added, the pound of alcohol which had been employed in the process for nitric ether for the purpose of absorbing the ether which escapes condensation in the receiver. Of course, after this addition, all the conditions are fulfilled which are necessary for the generation of spirit of nitric ether, namely, nitric acid in contact with more alcohol than is necessary to form ether. Accordingly, upon distillation, the nitric ether comes over mixed with a certain portion of alcohol, forming the spirit in question. But at the same time, a portion of acid is distilled over, to free it from which, the product is redistilled from an alkaline carbonate at a *medium* heat (between 100° and 200°) as long as any drops come over. To save the alkaline solution used in purifying nitric ether, it is directed to be applied, as far as it will go, to the purpose of saturating the acid of this preparation.

From the explanations here and previously given, it is obvious that the formulæ for nitric ether and sweet spirit of nitre of the Dublin College form in fact but one process; and whenever it is desirable to obtain nitric ether, it is no doubt economical to use the residue and part of the products of this process for preparing sweet spirit of nitre. But the fact is, that nitric ether is seldom or never employed in medicine, and has very few other uses; and hence the Dublin formula for the sweet spirit of nitre is ineligible, as including the preparation of another substance which may not be wanted. It is, no doubt, on this account, that the College has appended to its principal process another formula, (very nearly the same as that of the London College,) indicating the mode by which sweet spirit of nitre may be obtained independently of any other product.

The London and Edinburgh processes for this preparation are in principle the same, namely, the addition of nitric acid, ready formed, to alcohol; but the proportions employed are very different. In the London formula, the acid is to the alcohol as 1 to 8 nearly; in the Edinburgh, as 1 to 3. The proportion of nitric acid to alcohol for mutual reaction in the U.S. formula, is about the same as in the London process, if we suppose that the nitre, by its decomposition, yields a pound and a quarter of acid, which is about the quantity obtained in practice. This coincidence may be assumed with the greater confidence, as the preparation obtained by these two formulæ has about the same specific gravity. The proportion of alcohol in the Edinburgh formula is so deficient, that the product must be very strong in nitric ether. The directions of this College to keep the acid and alcohol mixed for seven days, answers no useful purpose, and is, therefore, a waste of time. The proportion of the spirit drawn off to the alcohol employed is different in the different formulæ. It is three-fourths in the London formula, five-sixths in that of the U.S. Pharm., and exactly equal to the alcohol employed in the Edinburgh. When the distillation is pushed too far, the product is apt to be contaminated with nitric acid. This risk is avoided almost entirely by the London College, by distilling only twenty-four fluidounces; but if accidentally the distillation be continued too long, a very acid liquor comes over. By following the directions of the Edinburgh formula, the acidity of the product would seem to be almost inevitable. From these considerations, we think that the London and Edinburgh Colleges have erred in not directing a rectification, as is ordered in the U.S. and Dublin Pharmacopœias.

Properties. Spirit of nitric ether is a colourless liquid, of a grateful ethereal odour, and, when recently prepared, of a very pungent, and slightly sweet and bitter taste. When kept for a few weeks, it acquires a decided acidity, and becomes sourish to the taste. When thus changed, it may be rectified by saturating the acid present with lime-water, and redistilling. It is very inflammable and volatile, but less so than sulphuric ether. It is readily soluble in water, and unites with any additional portion of alcohol to that which it already contains. Its sp. gr. is necessarily variable, as obtained by different formulæ. The density prescribed for it by the Dublin College is 0.850; but it ought not to exceed 0.834; which differs very little from the density of the officinal alcohol or rectified spirit, which weighs 0.835. The preparation as obtained by Mr. Carter's formula has the sp. gr. 0.833 at 65°. Unfortunately, however, specific gravity is not a criterion of its quality; as its appropriate density may be preserved, even after being weakened by a large quantity of alcohol. When tincture of guaiac is added to it, a peculiar blue tint is produced, which soon passes into various shades of green, without disturbing its transparency. Perhaps this tincture might afford the means of determining the quality of sweet spirit of nitre. Some test of this kind would be a highly desirable acquisition, on account of the extensive use made of this preparation, and the frequent sophistications to which it is subjected. It is stated on good authority, that it has been variously diluted, according to the views of the vender, with twice, thrice, and even four times its weight of alcohol and water. In some shops a strong and weak preparation has been kept, to suit the views of customers as to price. Some of the wholesale druggists are in the habit of diluting it, either under the plea that the physician's prescriptions are drawn up in contemplation of the use of a weak preparation, or for the purpose of affording it at a low price. All this confusion in regard to an important medicine would disappear, if the different manufacturing chemists in the Union would comply with the recommendation of the Philadelphia College of Pharmacy, and adopt for its preparation the formula of the United States Pharmacopœia. A uniform preparation being in this way furnished to the druggists, all that would be necessary on their part would be carefully to abstain from weakening it by the admixture of alcohol and water.

Sweet spirit of nitre is very prone to become acid by keeping; and a slight acidity is almost unavoidable. It is best preserved by being kept in accurately stopped half-pint bottles in a cool place. Its specific gravity ought not to exceed 0.834. If acid be present in considerable amount, it may be detected by the taste, by its acting strongly on litmus, or by effervescence being produced on the addition of a crystal of carbonate of soda. Its essential constituents are nitric ether and alcohol in proportions not well ascertained.

Medical Properties and Uses. Sweet spirit of nitre is diaphoretic, diuretic, and antispasmodic. It is deservedly much esteemed as a medicine, and is extensively employed in febrile affections for the purpose of promoting the secretions, especially those of sweat and urine. It often proves a grateful stimulus to the stomach, relieving nausea and removing flatulence, and not unfrequently allays restlessness and promotes sleep. On account of its tendency to the kidneys, it is often conjoined with other diuretics, such as squill, digitalis, nitre, &c., for the purpose of promoting their action in dropsical complaints. Dr. Duncan praises a combination of it with a small portion of aromatic spirit of ammonia, as eminently diaphoretic and diuretic, and well suited to certain states of febrile disease. The dose varies from twenty drops to a teaspoonful, given every two or three hours in a portion of water.

B.

ALCOHOL.

Preparations of Alcohol.

ALCOHOL DILUTUM. *U.S.* Spiritus Tenuior. *Lond.*, *Dub.* Alcohol Dilutius. *Ed.* *Diluted Alcohol.* *Proof Spirit.*

"Take of Alcohol, Distilled Water, each, *a pint*. Mix them." *U.S.*

The British Colleges have placed diluted alcohol or proof spirit in the list of the Materia Medica. The *London* College directs its sp. gr. to be 0.930. When of this strength, it contains 44 per cent. of pure alcohol, and may be formed by mixing four measures of their rectified spirit with three of water. In the *Dublin* Pharmacopœia, it is ordered of the sp. gr. 0.919, and the statement is made in a note, that spirit of almost the same specific gravity may be formed by mixing five and a quarter measures of rectified spirit, with three of distilled water. Such a spirit will contain about 49 per cent. of absolute alcohol. The directions of the *Edinburgh* College are more explicit; for it first explains that "Alcohol Dilutius" means "Alcohol Fortius" mixed with an equal measure of water, and then states its sp. gr. to be 0.935. It is perceived, therefore, that the diluted alcohol of the U. S. Pharmacopœia corresponds precisely with that of the Edinburgh College; being alcohol of the same strength diluted to an equal extent. Its sp. gr. must consequently be identical, or 0.935 also. Such spirit will contain 42 per cent. of absolute alcohol, and forms the weakest officinal diluted alcohol.

Medical and Pharmaceutical Uses. The medicinal effects of alcohol in a diluted and modified state, as it exists in brandy and other ardent spirits, have been detailed under other heads. (See *Alcohol* and *Vinum.*) As a pure diluted spirit, however, consisting solely of alcohol and water in determinate proportions, its use is exclusively pharmaceutical. It is employed as an addition to some of the distilled waters and preparations of vinegar, in order to preserve them from decomposition; as a menstruum for extracting the virtues of some plants, preparatory to their being brought to the state of extracts and syrups; and in preparing many of the spirits. But it is in forming the tinctures that diluted alcohol is principally employed. Many of these are formed with the officinal alcohol (rectified spirit), but the majority, with diluted alcohol (proof spirit) as the menstruum. As the latter contains more than half its weight of water, it is well fitted for acting on those vegetables, the virtues of which are partly soluble in water and partly in alcohol. The apothecary however is, on no account, to substitute the commercial proof spirit for diluted alcohol, even though it should be of the same strength. On this point, the authors of the Dublin Pharmacopœia have very correctly remarked, that "almost all the spirit which is sold under the name of proof spirit, is contaminated with empyreumatic oil, and unfit for medical use." But when it is recollected how variable the so called proof spirits are in strength, the objection to their use in pharmacy becomes still stronger. Thus, according to Mr. Brande, gin contains 51.6 per cent. of alcohol of 0.825; and the percentage of the same alcohol is 53.39 in brandy, 53.68 in rum, 53.90 in Irish whiskey, and 54.32 in Scotch whiskey. The alcohol on which these results are based already contains 11 per cent of water. B.

◆

ALUMEN.

Preparations of Alum.

ALUMEN EXSICCATUM. *U.S., Lond., Ed.* ALUMEN SICCATUM. *Dub. Dried Alum.*

"Take of Alum *any quantity*. Melt it in an earthen or iron vessel over the fire, and continue the heat till it becomes dry; then rub it into powder." *U.S.*

"Melt Alum in an earthen vessel over the fire; and then increase the heat until ebullition ceases." *Lond.*

The *Edinburgh* and *Dublin* processes agree with that of the U.S. Pharmacopœia. When alum is heated, it quickly dissolves in its water of crystallization, which, if the heat be continued, is gradually driven off; and the salt swells up exceedingly, so as to make it expedient to use a vessel, the capacity of which is at least equal to three times the bulk of the alum operated on. When the boiling up has ceased, it is a sign that all the water has been driven off, and the preparation is finished.

Properties. Dried alum is in the form of an opaque white powder, possessing a more astringent taste than the crystallized salt. Before pulverization, it is a light, white, opaque, porous mass. During the exsiccation, it loses from 41 to 46 per cent. of its weight in dissipated water. If, however, the heat be very strong, some of the acid is driven off, and the loss becomes still greater. Dried alum resists the action of water for a long time, showing that the process to which it has been subjected has altered its state of aggregation. In composition, it differs from crystallized alum merely in the absence of water. (See *Alumen.*)

Medical Properties and Uses. Dried alum has occasionally been given to the extent of a scruple in obstinate constipation, with the effect of gently moving the bowels, and of affording great relief from pain; but its principal medical use is as an escharotic for destroying fungous flesh. B.

LIQUOR ALUMINIS COMPOSITUS. *Lond.* *Compound Solution of Alum.*

"Take of Alum and Sulphate of Zinc, each, *half an ounce;* boiling Water *two pints.* Dissolve the Alum and Sulphate of Zinc in the Water, and filter through paper." *Lond.*

This was formerly called *aqua aluminosa Bateana,* or *Bates's alum water.* It is a powerful astringent solution, and is employed for cleansing and stimulating foul ulcers, and as an injection in gleet and leucorrhœa. It is also sometimes employed as a collyrium in ophthalmia after depletion; but when used in this way it must be diluted. A convenient formula is half a fluidounce of the solution mixed with six and a half fluidounces of rose water.

B.

* * *

AMMONIA.

Preparations of Ammonia.

ALCOHOL AMMONIATUM. *U.S., Ed.* SPIRITUS AMMONIÆ. *Lond., Dub.* *Ammoniated Alcohol.*

"Take of Alcohol [Rectified Spirit] *two pints and a half;* Lime, recently burnt, *a pound;* Muriate of Ammonia *eight ounces;* Water *six fluidounces.* From these let the Ammoniated Alcohol be prepared in the manner directed for Water of Ammonia." *U.S.*

"Take of Stronger Alcohol [Rectified Spirit] *thirty-two ounces;* fresh Lime *twelve ounces;* Muriate of Ammonia *eight ounces;* Water *six ounces.* Pour the Water on the pounded Lime in an iron or earthenware vessel; then cover the vessel until the lime falls to powder and becomes cold. Then mix the Muriate in very fine powder with the Lime, and rubbing them together n a mortar, immediately introduce them into a glass retort. Place the retort n a sand-bath, and fit on closely a receiver furnished with a tube which asses to the bottom of a bottle containing the alcohol, and of such a size as nly to be two-thirds full. Lastly, apply heat, and gradually increase it until the bottom of the iron pot becomes red, and continue it as long as gas and liquid come over." *Ed.*

"Take of Proof Spirit *three pints;* Muriate of Ammonia *four ounces;* Subcarbonate [Carbonate] of Potassa *six ounces.* Mix, and by means of a gentle heat, distil a pint and a half into a cooled receiver." *Lond.*

"Take of Rectified Spirit *three pints;* Carbonate of Ammonia, coarsely powdered, *three ounces and a half.* Mix them, and dissolve the salt with a medium heat; then filter the liquor." *Dub.*

The product of these processes is considerably different. The process of the *United States* Pharmacopœia is in effect the same as that of the *Edinburgh* College, the nearest measures for the liquids being merely substituted for weights. These two processes consist simply in the saturation of alcohol with gaseous ammonia, extricated from a mixture of lime and muriate of ammonia. On the other hand, the London and Dublin formulæ yield preparations in which carbonated ammonia is dissolved in alcohol. In the *London* process a double decomposition takes place between the muriate of ammonia and carbonate of potassa, resulting in the formation of carbonate of ammonia, which distils over with the proof spirit, and muriate of potassa, which remains behind in solution. Part, however, of the carbonate formed sublimes, the proof spirit, notwithstanding the water it contains, not being competent to dissolve the whole which comes over. The *Dublin* process is peculiar, and is characterized by Dr. A. T. Thomson as simple and elegant. It consists in dissolving the officinal carbonate in heated rectified spirit (Alcohol, *U.S.*). The officinal carbonate is a sesquicarbonate, and during its solution in the alcohol in this process, just so much carbonic acid is disengaged with effervescence, as to convert it into the regular carbonate, of which thirty grains dissolve in each fluidounce of the spirit. The preparation thus obtained, therefore, contains the ammonia in the same state in which it exists in that formed by the London process.

Properties. Ammoniated Alcohol, as obtained by the United States and Edinburgh formulæ, is a colourless liquid, of an exceedingly pungent smell and acrid taste. It consists of caustic ammonia dissolved in alcohol. The London and Dublin preparations have the same general properties, but in a milder degree, as they are solutions of carbonated ammonia in the same menstruum. They are more pungent and alkaline than if they contained the sesquicarbonate, as the ammonia present is combined with less carbonic acid than in that carbonate. They are capable, as well as the two former preparations, of dissolving camphor and the volatile oils.

Medical Properties and Uses. These preparations are exceedingly stimulant, especially those of the United States and Edinburgh Pharmacopœias. They are sometimes given in flatulent colic and nervous debility, in doses of from twenty to fifty drops, in two or three tablespoonfuls of water. The stronger preparations, when saturated with camphor, form a very highly stimulating liniment.

Ammoniated alcohol is principally employed for the purpose of forming the class of preparations called *Ammoniated Tinctures.* B.

ALCOHOL AMMONIATUM AROMATICUM. *U.S.* SPIRITU AMMONIÆ AROMATICUS. *Lond., Dub.* TINCTURA AROMATICA AMMONIATA. *Ed.* *Aromatic Ammoniated Alcohol.*

"Take of Ammoniated Alcohol *a pint;* Oil of Rosemary, Oil of Lemons each, *two fluidrachms;* Oil of Cloves, Oil of Cinnamon, each, *half a flu drachm.* To the Oils, previously mixed, add the Ammoniated Alcoho and pour upon them so much water, that, after distillation, sufficient may remain to prevent empyreuma; then, with a gentle heat, distil a pint." *U.S.*

"Take of Cinnamon Bark, bruised, Cloves, bruised, each, *two drachms;* Lemon Peel *four ounces;* Subcarbonate [Carbonate] of Potassa *half a pound;* Muriate of Ammonia *five ounces;* Rectified Spirit *four pints;* Water *a gallon;* Mix, and let six pints be distilled." *Lond.*

"Take of Ammoniated Alcohol *eight ounces;* Volatile Oil of Lemon Peel *a drachm;* Volatile Oil of Rosemary *a drachm and a half;* Mix them, that the Oils may be dissolved." *Ed.*

"Take of Spirit of Ammonia *two pints;* Essential Oil of Lemons *two drachms;* Nutmegs, bruised, *half an ounce;* Cinnamon Bark, bruised, *three drachms.* Macerate in a covered vessel for three days, shaking occasionally; then distil a pint and a half." *Dub.*

These processes all furnish Ammoniated Alcohol, impregnated with volatile oils. In the United States and Dublin formulæ, the ammoniated alcohol is distilled with the aromatics; in the London, the materials for forming it are thus distilled; while the Edinburgh College dissolves the aromatics in the menstruum, without resorting to distillation. The process of the *United States* Pharmacopœia has been found to afford a pleasant preparation. In the *London* process, the carbonate of potassa directed is insufficient to decompose the whole of the muriate of ammonia, the proportions used in the London spirit of ammonia being injudiciously departed from. Four pints of Rectified Spirit are taken, but six pints of product are drawn off: showing that the London preparation is a solution of carbonate of ammonia in *diluted* alcohol, impregnated with aromatics. The *Dublin* preparation is the same, except that the menstruum is undiluted alcohol, or rectified spirit. The *Edinburgh* process is objectionable on account of the omission of distillation; for if the volatile oils contain impurity, the preparation which results will be coloured and turbid, a defect which is avoided by distillation, as the impurities are thus left behind.

Medical Properties and Uses. These preparations, though analogous, are by no means identical, differing considerably in strengh, according as the alcoholic menstruum contains caustic or carbonated ammonia. They are much more used than the preceding preparations, on account of their more grateful taste, derived from the aromatics; but their medical effects are similar. The dose is from twenty to sixty drops, in one or two wineglassfuls of water. They are compatible with sulphate of magnesia, and may be usefully added to aperient draughts of that salt, to render them less offensive to the stomach.

Off. Prep. Tinctura Guaiaci Ammoniata, *U.S.*, *Lond.*, *Dub.;* Tinctura Valerianæ Ammoniata, *U.S.*, *Lond.*, *Dub.* B.

AMMONIÆ CARBONAS. *U.S.*, *Dub.* AMMONIÆ SUBCARBONAS. *Lond.* SUB-CARBONAS AMMONIÆ. *Ed.* *Carbonate of Ammonia. Mild volatile alkali.*

"Take of Muriate of Ammonia *a pound;* Carbonate of Lime, dried, *a pound and a half.* Pulverize them separately; then mix them thoroughly, and sublime from a retort into a receiver kept cold." *U.S.*

"Take of Muriate of Ammonia *one part;* Softer Carbonate of Lime, dried, *two parts.* Having triturated them separately, mix them thoroughly, and sublime from a retort into a refrigerated receiver." *Ed.*

"Take of Muriate of Ammonia, pulverized and well dried, Dried Carbonate of Soda, each, *one part.* Put the mixture into an earthenware retort, and with a heat gradually increased, sublime the Carbonate of Ammonia into a refrigerated receiver." *Dub.*

The *London* differs from the United States process, in ordering the heat to be continued until the retort becomes red hot, and in omitting the refrigeration of the receiver.

In the above processes, by the reciprocal action of the salts employed, the carbonic acid unites with the ammonia, generating carbonate of ammonia, and the muriatic acid with the lime or soda, so as to form water and chloride of calcium, or the same liquid and chloride of sodium. The carbonate and water sublime together as a hydrated carbonate of ammonia, and the residue is chloride of calcium, or, in the case of the Dublin formula, chloride of sodium, or common salt. In conducting this process, the retort should be of earthenware, and have a wide cylindrical neck; and the receiver should be cylindrical, to facilitate the extraction of the sublimate. The relative quantities of chalk and muriate of ammonia for mutual decomposition, are 50.62 of the former and 53.57 of the latter, or one equiv. of each. The different Pharmacopœias, therefore, use a great excess of chalk. A small excess is desirable, to ensure the perfect decomposition of the muriate of ammonia, any redundancy of which would sublime along with the carbonate and render it impure. The employment of carbonate of soda, in the Dublin process, affords a product of greater whiteness, but is objectionable on the score of expense. The proportions of the muriate and alkaline carbonate, directed by this College, correspond precisely with the equivalents; but in practice, the quantity of carbonate of soda is found insufficient.

Carbonate of ammonia is obtained on a large scale, generally by subliming the proper materials from an iron pot, into a large earthen or leaden receiver. Sulphate of ammonia may be substituted for the muriate with much economy, as has been shown by Payen. Large quantities of this carbonate are also manufactured from the products of the distillation of coal in gas works; but the salt thus obtained is apt to have a slight odour of tar, and to leave a blackish carbonaceous matter when dissolved in acids.

Properties. Carbonate of ammonia, recently prepared, is in white, moderately hard, translucent masses, of a fibrous and crystalline appearance, a pungent smell, and a sharp penetrating taste. It possesses an alkaline reaction, and when held under a piece of turmeric paper changes it to brown, owing to the ammonia which escapes. When long or carelessly kept, it gradually passes into the state of bicarbonate, becoming opaque and friable, and much less pungent. It is soluble in about four times its weight of cold water, and is decomposed by boiling water with effervescence of carbonic acid. According to Dr. Barker, (*Observations on the Dublin Pharmacopœia,*) it dissolves abundantly in diluted alcohol; as also in heated alcohol of the sp. gr. 0.836, with effervescence of carbonic acid. When heated on a piece of glass, it ought to evaporate without residue, and if turmeric paper held over it undergoes no change, it is proved to have passed into bicarbonate. It is decomposed by acids, alkalies and their carbonates, lime-water and magnesia, muriate of lime and supertartrate of potassa, the preparations of iron (except the tartrate of iron and potassa), corrosive sublimate, the acetate and subacetate of lead, and the sulphates of iron and zinc.

Composition. It consists, according to Mr. Philips, of three equiv. of carbonic acid 66.36, two of ammonia 34.3, and two of water 18=118.66; or which comes to the same thing, of one equiv. of bicarbonate 61.39, and one of the regular carbonate 39.27, combined with the same quantity of water. The medicinal carbonate of ammonia, when perfect, is, therefore, a hydrated *sesquicarbonate*, and not a subcarbonate, as called by the London and Edingburgh Colleges. When converted into bicarbonate by exposure to the air, every two equiv. of it may be supposed to lose one equiv. of ammonia, a change which would leave the acid and base in the proper proportion to form the bisalt. The mutual decomposition of the salts employed in its preparation, would generate, if no loss occurred, the regular carbonate, and not a sesquicarbonate. The way in which the latter salt is formed may be thus explained. By the mutual decomposition of three equiv. of muriate of ammonia and of chalk respectively, three equiv. of carbonate of ammonia, three of water, and three of chloride of calcium would be generated. During the operation, one equiv. of ammonia and one of water are lost; so that there remain to be sublimed, three equiv. of carbonic acid, two of ammonia, and two of water, or in other words, the exact constituents of the hydrated sesquicarbonate.

Medical Properties and Uses. Carbonate of ammonia is stimulant, diaphoretic, antispasmodic, powerfully antacid, and in large doses emetic. Under certain circumstances it may prove expectorant; as when, in the last stages of phthisis, it facilitates, by increasing the muscular power, the excretion of the sputa. As a stimulant, it is exhibited principally in typhus fever, and very frequently in connexion with wine whey. Its principal advantage in this disease, is its power to increase the action of the heart and arteries, without unduly exciting the brain. It is employed, with a view to the same effect, and as an antacid, in certain states of atonic gout, and in the derangements of the stomach supervening on habits of irregularity and debauchery. As a diaphoretic, it is resorted to in gout and chronic rheumatism, particularly the latter, in conjunction with guaiac. It is very seldom used as an emetic; but is said to act with advantage, in this way, in some cases of paralysis. As an external application, it is rubefacient, and may be employed in several ways. Reduced to fine powder, and mixed with some mild ointment, it is useful in local rheumatism. One part of it, incorporated with three parts of extract of belladonna, forms a plaster very efficacious in relieving local and spasmodic pains. Coarsely bruised, and scented with oil of lavender, it constitutes the common smelling salts, so much used as a nasal stimulant in syncope and hysteria. The dose as a stimulant, is from five to ten grains, every two, three, or four hours, in the form of pill, or dissolved in some aqueous vehicle; and as an emetic, thirty grains, to be repeated if necessary, and assisted by free dilution. It should never be given in powder, on account of its volatile nature. Pills of it may be made up with some vegetable extract, as of chamomile for example, and should be dispensed in a wide mouthed phial, and not in a box.

Off. Prep. Cuprum Ammoniatum, *U.S.*, *Lond.*, *Ed.*, *Dub.;* Liquor Ammoniæ Acetatis, *U.S.*, *Lond.*, *Ed.*, *Dub.;* Liquor Ammoniæ Subcarbonatis, *Lond.*, *Ed.*, *Dub.;* Spiritus Ammoniæ, *Dub.* B.

LIQUOR AMMONIÆ SUBCARBONATIS. *Lond.* SOLUTIO SUB-CARBONATIS AMMONIÆ. *Ed.* AMMONIÆ CARBONATIS AQUA. *Dub.* *Solution of Subcarbonate of Ammonia.*

"Take of Subcarbonate of Ammonia *four ounces*, [one part, *Ed.*]; Distilled Water *a pint*, [four parts, *Ed.*]. Dissolve the Subcarbonate of Ammonia in the Water, and filter through paper." *Lond.*

"Take of Carbonate of Ammonia *four parts;* Distilled Water *fifteen parts.* Dissolve the Carbonate of Ammonia in the Water, and filter through paper. The specific gravity of the solution is 1.090." *Dub.*

This preparation may be viewed as a saturated aqueous solution of carbonate of ammonia, the proportions employed being but slightly different, as directed by the different Colleges. It is very properly omitted in the United States Pharmacopœia, as it is liable to change by keeping. The dose is from half a fluidrachm to a fluidrachm, given in any bland liquid.

Off. Prep. Ammoniæ Bicarbonas, *Dub.;* Linimentum Ammoniæ Subcarbonatis, *Lond.* B.

AMMONIÆ BICARBONAS. *Dub.* *Bicarbonate of Ammonia.*

"Take of Water of Carbonate of Ammonia *any quantity.* Expose it, in a suitable apparatus, to a stream of carbonic acid gas, evolved during the solution of white marble in Diluted Muriatic Acid, until the alkali is saturated. Then let it rest to form crystals, which are to be dried without heat, and kept in a closely stopped vessel." *Dub.*

This salt has been made officinal in the last revision of the Dublin Pharmacopœia, and is peculiar to that work. The process by which it is formed consists in saturating the sesquicarbonate (officinal carbonate) with carbonic acid, whereby this salt becomes a bicarbonate. The sesquicarbonate consists of three equiv. of acid, two of ammonia, and two of water; and, by gaining one equiv. of carbonic acid, becomes a bicarbonate, consisting of four equiv. of acid, two of ammonia, and two of water. These proportions reduced to their lowest terms give for the composition of this bisalt, two equiv. of carbonic acid, one of ammonia, and one of water. The above is the rationale of the formation of this salt given by Dr. Barker, the Commentator on the Dublin Pharmacopœia; but it is probable that the bicarbonate obtained by the Dublin process, as it is crystallized from solution, contains more than one equiv. of water.

Bicarbonate of ammonia, as prepared by this process, is in the form of crystals, which are much less ammoniacal in taste and smell, and more permanent in the air, than the sesquicarbonate. It is also less soluble in water, requiring eight times its weight of that liquid to dissolve it. It possesses, though in an inferior degree, the medical properties of the sesquicarbonate. As it furnishes the practitioner with the means of prescribing ammonia in a convenient and palatable form, Dr. Barker deems its introduction into the officinal list of the Dublin College, a valuable improvement. It ought to have been shown, however, in what respect the Dublin preparation differs from the bicarbonate, obtained by exposing the sesquicarbonate to the air; for if they be identical, it cannot be necessary to resort to the Dublin formula for preparing this bisalt. The dose of bicarbonate of ammonia is from six to twenty-four grains, dissolved in cold water, as hot water decomposes it. B.

AQUA AMMONIÆ. *U.S.*, *Ed.* LIQUOR AMMONIÆ. *Lond.* AMMONIÆ CAUSTICÆ AQUA. *Dub.* *Water of Ammonia.*

"Take of Muriate of Ammonia, in very fine powder, *a pound*; Lime, recently burnt, *a pound and a half*; Distilled Water *a pint*; Water *nine fluidounces.* Break the lime in pieces, and pour the Water upon it, in an earthen or iron vessel; then cover the vessel, and set it aside till the Lime falls into powder, and becomes cold. Mix this thoroughly with the Muriate of Ammonia in a mortar, and immediately introduce the mixture into a glass retort. Place the retort upon a sand-bath, and adapt to it a receiver, previously connected, by means of a glass tube, with a quart bottle containing the Distilled Water. Then apply heat, to be gradually increased till the bottom of the iron vessel containing the sand becomes red hot; and continue the process so long as the Ammonia comes over. Remove the liquor contained in the quart bottle, and preserve it in small phials well stopped. The specific gravity of Water of Ammonia is 0.944." *U.S.*

"Take of Muriate of Ammonia *eight ounces;* fresh Lime *six ounces;*

Water *four pints.* Pour a pint of the Water upon the Lime; then cover the vessel, and set it aside for an hour. Next add the Muriate of Ammonia and the rest of the Water previously heated to ebullition, and again cover the vessel. Strain the liquor after it has become cold, and distil from it twelve fluidounces of Solution of Ammonia into a receiver, the temperature of which does not exceed 50°. The specific gravity of Solution of Ammonia is 0.960." *Lond.*

"Take of Muriate of Ammonia, in powder, *three parts;* Lime, recently burnt, *two parts;* Water *ten parts.* Pour one part of the Water, previously heated, on the Lime, placed in an earthen vessel, and cover it. Dissolve the salt in the remainder of the Water, also heated. When the lime has fallen into powder and become cool, put it into a retort, and add to it the saline solution also cold. Then distil five parts with a medium heat into a refrigerated receiver. The specific gravity of this Solution is 0.950. *Dub.*

The *Edinburgh* process for this preparation is nearly the same with that of the U.S. Pharmacopœia; the latter having been copied from the former, with the unimportant differences of substituting a pint of distilled water for a pound, and nine fluidounces of water for nine ounces, changes which cause the U.S. preparation to be somewhat weaker than the Edinburgh, which has the sp. gr. 0.939.

The object of the above processes is to obtain an aqueous solution of the alkaline gas ammonia. The muriate of ammonia is decomposed by the superior affinity of the lime for its acid, ammonia is disengaged, and the lime combining with the acid, forms chloride of calcium and water. The ammonia is either evolved from the dry materials, and passed into water, by which it is absorbed, as in the U.S. and Edinburgh processes, or distilled over in connexion with water, as directed by the London and Dublin Colleges. The lime is required to be recently burnt, to ensure its causticity; for if partly carbonated, it would give rise to a portion of carbonate of ammonia. It is slaked to render it pulverulent, in which state, it acts more readily on the finely pulverized muriate of ammonia. The receiver directed in the *United States* process is intended to retain any water holding in solution undecomposed muriate, or oily matter sometimes contained in this salt, which may be driven over by the heat; while the pure gas passes forward through the glass tube into the bottle containing the distilled water, which should not more than half fill it, on account of the increase of bulk which it acquires during the absorption of the gas. The tube should continue down to near the bottom of the bottle, and pass through a cork, which loosely fits its mouth. To prevent the regurgitation of the water from the bottle into the receiver, the latter should be furnished with a Welter's tube of safety. Large bottles are improper for keeping the water of ammonia obtained; as when partially empty, the atmospheric air contained within them is apt to furnish some carbonic acid to the ammonia.

In the *London* process, a boiling solution of muriate of ammonia being added to the slaked lime, the decomposition of the muriate takes place before the distillation is commenced, and results in the extrication of ammonia which dissolves in part of the water, and in the formation of muriate of lime in solution. An excess of lime being used, the object of straining is to separate it, and, consequently, the clear liquid contains nothing but the mixed solutions of ammonia and of muriate of lime. When subjected to distillation, so as to draw off a limited portion of liquid, the solution of ammonia comes over, and the muriate of lime is left behind dissolved in the larger part of the water. The receiver is not allowed to exceed the temperature of 50°, in order to prevent the loss of gas which the high temperature of the product might occasion. The principle of the *Dublin* process is the same as that of the London. The difference consists in dispensing with the straining, so that the residue of the operation consists of the solution of muriate of lime, mixed with the superabundant lime. Dr. Barker objects to the Dublin formula that the ammonia is apt to be generated in the retort faster than the water present can take it up, which circumstance causes a loss. He, therefore, believes it would be an improvement in the formula to direct that part of the water should be placed in the receiver.

The proportion of lime is very different, as used in the different formulæ. The equivalent proportions are 53.57 of salt to 28.5 of lime; or a quantity of the latter only a little more than half the weight of the former. By the numbers expressing the proportions of the ingredients employed, it is shown, therefore, that all the Pharmacopœias use an excess of lime, the excess being least in the Dublin. The earth is particularly in excess in the U.S. and Edinburgh processes, and Mr. Phillips alleges that its bulk is an inconvenience by requiring large vessels; but Dr. Hope contends that the excess of lime is useful by accelerating the disengagement of the ammonia, and by rendering a less elevated temperature necessary. The excess of lime, to the extent directed by the Dublin College, is stated by Dr. Barker to be necessary to compensate for the impurities in ordinary lime. The use of no more lime than is absolutely required, has the incidental advantage of rendering the residual solution of muriate of lime less impure; an object of some importance where it is reserved for purification, as is done by the Dublin College.

Water of ammonia is usually prepared in large quantities by the manufacturing chemist. To save the expense of glass or earthenware retorts, a cast iron boiler is employed, furnished with a copper head, which communicates with glass receivers, arranged as already explained. The materials being placed in the boiler, the head is luted on with a mixture of lime and white of eggs. This apparatus, according to Thenard, offers the advantages of allowing considerable quantities of the materials to be operated on at a time, and of permitting an admixture of water, which, by bringing the lime to a pasty consistence, facilitates remarkably the decomposition of the muriate. When a strong water of ammonia is required, the water employed to absorb the gas should equal in weight the muriate decomposed. The manufacturing chemists generally obtain a very strong solution, and afterwards reduce it to the medicinal standard, as ascertained by its specific gravity, by the addition of the requisite portion of water. Sulphate of ammonia may be used in this process, instead of the muriate, as proposed by Payen, with economical results.

Properties. Water of ammonia is a colourless liquid, of a caustic, acrid taste, and peculiar, pungent smell. It is strongly alkaline, and immediately changes turmeric to reddish-brown, when held over its fumes. When concentrated, it blisters the tongue and skin. Cooled down to 40° below zero, it concretes into a gelatinous mass, and at the temperature of 130°, enters into ebullition, owing to the rapid disengagement of the gas. It possesses a very strong affinity for carbonic acid, and when insecurely kept, attracts it from the atmosphere. When pure, it evaporates in a glass capsule without residue. The presence of carbonic acid may be detected by its effervescing with acids, and affording a precipitate when poured into lime-water. It unites with oils forming a liquid soap, and dissolves resins and many other vegetable principles. Its sp. gr. is in an inverse proportion to its strength. When as concentrated as possible, it weighs 0.875 at the temperature of 50°. Its sp. gr. in its various officinal states has been already indicated. It is incompatible with all the acids, and with most of the earthy and metallic salts.

Composition. Water is capable of absorbing a third of its weight, or 430 times its volume of ammoniacal gas, and increases in bulk about two-thirds. But the officinal water of ammonia is by no means saturated. Thus the percentage of ammonia contained in the preparations of the different Pharmacopœias is nearly as follows:—London 10 per cent.; Dublin 12½; U. S. 14½; and Edinburgh 15.8. The following table, constructed by Sir H. Davy, gives the percentage of ammoniacal gas in aqueous solutions of different specific gravities.

Specific Gravity.	Ammonia per cent.	Specific Gravity.	Ammonia per cent.	Specific Gravity.	Ammonia per cent.
0.8750	32.50	0.9326	17.52	0.9545	11.56
0.8875	29.25	0.9385	15.88	0.9573	10.82
0.9000	26.00	0.9435	14.53	0.9597	10.17
0.9054	25.37	0.9476	13.46	0.9619	9.60
0.9166	22.07	0.9513	12.40	0.9692	9.50
0.9255	19.54				

Properties of Gaseous Ammonia. All the ammoniacal compounds owe their distinctive properties to the presence of a peculiar gaseous compound of hydrogen and nitrogen, called ammonia. It is most easily obtained by the action of lime upon muriate of ammonia. It is transparent and colourless like common air, but possesses an acrid and hot taste, and an exceedingly pungent smell. It has a powerful alkaline reaction, and from its gaseous nature, was called the *volatile alkali* by the earlier chemists. Its sp. gr. is 0.59. It is irrespirable, the glottis closing spasmodically when the attempt is made to breathe it. It consists of one equiv. of nitrogen 14.15, and three of hydrogen 3=17.15; or in volumes, of one volume of nitrogen and three volumes of hydrogen, condensed into two volumes.

Medical Properties and Uses. Water of ammonia is stimulant, antacid, and rubefacient. It is rarely used internally, other ammoniacal preparations being preferred, the dose of which is larger and more easily managed. As a stimulant, it is occasionally employed in paralysis, hysteria, syncope, asphyxia, and similar affections, with a view to rouse the vital powers. In the same complaints it is often applied to the nostrils with advantage. As an antacid, it is one of the best remedies in heartburn, and for the relief of sick headach, when dependent on acidity of stomach. In these cases it acts usefully also as a stimulant. Externally applied, it may be made to act either as a rubefacient or vesicatory. As a rubefacient it is employed united to oil in the form of volatile liniment. (See *Linimentum Ammoniæ.*) As a vesicatory, it is applied by means of a piece of linen wet with it. The dose is from five to twenty drops, largely diluted with water to prevent its caustic effect on the mouth and throat. In graduating the dose, the particular officinal preparation employed must be taken into the account; as these differ considerably in strength. It is on account of the high strength of the water of ammonia of the Edinburgh College, considered as a medicine, that a diluted preparation is directed by that College under a separate name. (See *Aqua Ammoniæ Diluta*, Ed.) When swallowed in an over-dose, its effects are those of a corrosive poison. The best antidote that can be used is vinegar, which acts by neutralizing the ammonia, and which must be promptly applied to be useful. The consecutive inflammation must be treated on general principles.

Water of ammonia is used pharmaceutically, as a precipitant, in preparing morphia (*U.S.*), the precipitated phosphate of lime (*Dub.*), and the oxide of zinc (*U.S.*, *Lond.*)

Off. Prep. AQUA AMMONIÆ DILUTA. *Ed. Diluted Water of Ammonia.*

"Take of Water of Ammonia *one part;* Distilled Water *two parts.* Mix them." *Ed.*

The Edinburgh College, considering their water of ammonia to be inconveniently if not dangerously strong for internal exhibition, have directed this formula for its dilution. It is true that the strong preparation is always diluted at the moment it is taken; but the objection to it still holds, that it is exceedingly pungent, and its dose, being only a few drops, is not so convenient to apportion, and may be given by mistake, unduly concentrated. This preparation is, of course, one-third of the strength of the strong water of ammonia of this College, or will contain about 5.3 per cent. of ammonia. Its dose is from fifteen to thirty drops, sufficiently diluted with water. B.

LIQUOR AMMONIÆ ACETATIS. *U. S., Lond.* AQUA ACETATIS AMMONIÆ. *Ed.* AMMONIÆ ACETATIS AQUA. *Dub. Solution of Acetate of Ammonia. Spirit of Mindererus.*

"Take of Diluted Acetic Acid *a pint;* Carbonate of Ammonia, in powder, *a sufficient quantity.* Add the Carbonate of Ammonia gradually to the Acid, stirring constantly, until effervescence ceases." *U.S.*

"Take of Subcarbonate of Ammonia *two ounces;* Diluted Acetic Acid [Distilled Vinegar] *four pints*, or *a sufficient quantity.* Add the Acid to the Subcarbonate of Ammonia, until effervescence ceases, and mix." *Lond.*

"Take of Sub-Carbonate of Ammonia, in powder, *any quantity;* Weak Acetic Acid [Distilled Vinegar] *a sufficient quantity.* Add the Acid gradually until the Sub-Carbonate is accurately saturated." *Ed.*

"Take of Carbonate of Ammonia *one part.* Add gradually, and with frequent agitation, as much warm Distilled Vinegar as may be necessary to saturate the ammonia, namely, about *thirty parts.* The saturation may be ascertained by means of litmus." *Dub.*

This preparation is an aqueous solution of acetate of ammonia. The process by which it is formed constitutes a case of single elective affinity. The acetic acid decomposes the carbonate, combines with the ammonia, forming the acetate of ammonia, and disengages the carbonic acid, the escape of which causes the effervescence. The British Colleges employ distilled vinegar, while, according to the United States Pharmacopœia, the saturation is effected with a pure acetic acid, diluted to a determinate extent with water. (See *Acidum Aceticum Dilutum*, U. S.) The use of the acid in the latter form is a decided improvement; for besides furnishing the solution of the acetate of uniform strength, a result which cannot be attained by the employment of distilled vinegar, it avoids the production of a brownish solution, which uniformly follows the use of the latter, especially when it has been condensed in a metallic worm. The quantity of carbonate of ammonia necessary to saturate a given weight of the acid of average strength, cannot be laid down with precision, on account of the variable quality of this salt. When the acid is of the sp. gr. 1.009, Mr. Philips found a pint of it to require for saturation within a few grains of seven drachms. The addition of the salt to the acid, as directed in the U. S. Pharmacopœia, is more convenient than the contrary order; as the point of saturation is thus more easily attained. This point is best ascertained by the alternate use of turmeric and litmus paper; and it is a good rule to allow rather a slight acidity to prevail, which will be due to carbonic acid dissolved in the liquid, and will disappear as soon as this acid is dissipated by time.

Properties. Solution of acetate of ammonia, when made of pure materials, is a limpid and nearly colourless liquid. Its taste is saline and resembles that of a mixture of nitre and sugar. It should not be made in large quantities at a time, as its acid becomes decomposed, and a portion of carbonate of ammonia is generated. As formerly prepared, under the name of *spiritus Mindereri*, it was made from the impure carbonate of ammonia, containing animal oil, which modified the product by giving rise to a portion of ammoniacal soap. It is incompatible with acids, the fixed alkalies and their carbonates, lime-water, magnesia, sulphate of magnesia, corrosive sublimate, the sulphates of iron, copper, and zinc, and nitrate of silver. When it contains free carbonic acid, it produces with the acetate or subacetate of lead, a precipitate of carbonate of lead, which being mistaken for the sulphate, has sometimes led to the erroneous supposition of the presence of sulphuric acid in the distilled vinegar, when this has been employed. Acetate of ammonia, the salt in solution in this preparation, is difficultly crystallizable, and very deliquescent. It may be obtained by sublimation, from a mixture of equal parts of dry acetate of potassa or of lime, and muriate of ammonia. It consists of one equiv. of acetic acid 51.48, and one of ammonia 17.15=68.63. When crystallized it contains seven equiv. of water 63.

Medical Properties and Uses. Solution of acetate of ammonia is a valuable diaphoretic, much employed in febrile and inflammatory diseases. According to the indications to be answered by its use, it is variously combined with nitre and antimonials, camphor and opium. If, instead of promoting its determination to the skin by external warmth, the patient walk about in a cool air, its action will be directed to the kidneys. It is sometimes used externally as a discutient. Mr. Brande speaks of it as an excellent application in mumps, applied hot upon a piece of flannel. Mixed in the proportion of a fluidounce with seven fluidounces of rose-water, and two fluidrachms of laudanum, it forms a useful collyrium in chronic ophthalmia. Dr. A. T. Thomson has used it as a lotion with the best effect in a case of porrigo affecting the scalp. The dose is from half a fluidounce to a fluidounce and a half, every three or four hours. It proves sometimes very grateful to febrile patients, when mixed with an equal measure of carbonic acid water.

B.

LIQUOR AMMONIÆ HYDROSULPHATIS. *U.S.* HYDRO-SULPHURETUM AMMONIÆ. *Ed.* AMMONIÆ HYDROSULPHURETUM. *Dub.* *Solution of Hydrosulphate of Ammonia. Hydrosulphuret of Ammonia.*

"Take of Water of Ammonia *four fluidounces.* Pass Hydrosulphuric Acid through the Water of Ammonia, in a suitable vessel; to perfect saturation. Let the solution be kept in a well stopped bottle.

"Hydrosulphuric Acid is obtained from the Sulphuret of Iron, and Sulphuric Acid diluted with four times its weight of water." *U.S.*

"Take of Water of Ammonia, Sulphuret of Iron, each, *four ounces;* Muriatic Acid *eight ounces;* Water *two pounds and a half.* Pour the Acid, previously mixed with the Water, upon the Sulphuret, and pass the Gas extricated from them through the Water of Ammonia. Keep the solution in a phial, very well stopped." *Ed.*

"Take of Sulphuret of Iron, in coarse powder, *five parts;* Sulphuric Acid *seven parts;* Water *thirty-two parts;* Water of Caustic Ammonia *four parts.* Put the Sulphuret into a retort; then gradually pour on the Acid, previously diluted with the Water, and in a suitable apparatus, transmit the gas evolved through the Water of Ammonia. Towards the end of the process, apply a gentle heat to the retort." *Dub.*

This preparation is a solution of hydrosulphate of ammonia in water, and is formed by passing a stream of hydrosulphuric acid gas (sulphuretted hydrogen) through a portion of water of ammonia, usually contained in a Wolfe's bottle. In the United States and Dublin processes, the hydrosulphuric acid is generated by the action of dilute sulphuric acid on sulphuret of iron. The water yields its oxygen to the iron forming protoxide of iron, with which the sulphuric acid combines; while the hydrogen of the water, uniting with the sulphur, gives rise to the hydrosulphuric acid. In the Edinburgh formula, the same acid is formed by the action of dilute muriatic acid on sulphuret of iron; in which case the rationale is similar to the above, the only difference being that the residual salt is a muriate instead of a sulphate of iron. In the Edinburgh and Dublin processes, the ingredients, in certain specified quantities, for producing the hydrosulphuric acid, are enumerated in the formula; in the United States process, the mode of obtaining it is explained in a general way in an appended paragraph. In the two former processes, the gas extricated from the given weight of ingredients is supposed to be all absorbed by the water of ammonia; in the latter, the limit to the generation of the gas is the accomplishment of the complete saturation of the alkali, which is the better rule. Sulphuric acid is to be preferred to muriatic acid for extricating the gas, as well on account of its cheapness, as of its fixed nature, which makes it less liable than muriatic acid to come over and contaminate the product.

Properties. Solution of hydrosulphate of ammonia is a liquid of a greenish-yellow colour, very fetid smell, and acrid and disagreeable taste. It is characterized by giving coloured precipitates with neutral metallic solutions, for which it is much used as a test. It is decomposed by acids, which cause the escape of hydrosulphuric acid with effervescence, and the deposition of sulphur.

Medical Properties and Uses. This preparation acts on the system as a powerful sedative, lessening the action of the heart and arteries in a remarkable degree, and producing nausea and vomiting, vertigo, and drowsiness. It has been used in diabetes mellitus, in which disease it was proposed as a remedy by Mr. Cruickshank, for the purpose of lessening the morbid appetite, which often attends that affection, and has been employed by Dr. Rollo and others. The dose is from five to six drops in a tumblerful of water three or four times a day, to be gradually increased until giddiness is produced. B.

ANTIMONIUM.

Preparations of Antimony.

ANTIMONII OXYDUM NITROMURIATICUM. *Dub. Nitromuriatic Oxide of Antimony. Powder of Algaroth.*

"Take of Prepared Sulphuret of Antimony *twenty parts;* Muriatic Acid *one hundred parts;* Nitric Acid *one part.* Add the Sulphuret gradually to the Acids, previously mixed in a glass vessel, avoiding the vapours. Digest with a heat gradually increased, until the effervescence cease, and then boil for an hour. Receive the cooled and filtered liquor in a gallon of water. Wash the Oxide of Antimony, after it has subsided, repeatedly, in a sufficiently large quantity of water, until the liquid poured off be perfectly free from acid, as known by the test of litmus. Lastly, dry the oxide on bibulous paper."

The object of this process is to obtain the oxy-chloride of antimony, consisting of sesquioxide and sesquichloride of antimony, formerly called *powder of Algaroth.* When sulphuret of antimony is dissolved by the aid of heat, in muriatic acid, a double decomposition takes place, resulting in the formation of sesquichloride of antimony (butter of antimony) and hydrosulphuric acid (sulphuretted hydrogen), which by its evolution causes the effervescence. When the sesquichloride is poured into a large quantity of water, part of it is converted into muriatic acid and sesquioxide, the former remaining in solution united with the major part of the undecomposed sesquichloride, the latter falling in union with a small portion of the same chloride, as a white flocculent precipitate, constituting the oxy-chloride, or powder of Algaroth. The precipitate is washed for the purpose of freeing it from adhering muriatic acid. The heat should be applied moderately at first, for fear the materials should unduly swell; but towards the close of the process it ought to be increased, to ensure the complete action of the acid. The small portion of nitric acid used by the College, is not essential to the success of the process; but is useful for decomposing any remains of hydrosulphuric acid which may exist in the solution, and which, by its presence, would impair the whiteness of the oxy-chloride, when precipitated in the next step of the process by the water. The employment of nitric acid, for the purpose of giving whiteness to the product of this formula, originated with Dr. Perceval of Dublin. There exists a defect in the formula; inasmuch as the ingredients are taken in parts, which are *relative* quantities, while the water is directed in the *absolute* quantity of a gallon.

Properties. Oxy-chloride of antimony is in the form of a white powder. When exposed to a red heat, it enters into fusion, and forms a yellow liquid, which, on cooling, concretes into a grayish crystalline mass, of a pearly aspect. It consists mainly of sesquioxide, containing only, according to Phillips, about 8 per cent. of chlorine.

Medical Properties and Uses, &c. Powder of Algaroth was formerly used in medicine, but, owing to its unequal operation, has been laid aside. It is employed in pharmacy in the preparation of tartar emetic, for which purpose it is placed among the preparations of the Dublin Pharmacopœia. It is also applied to the same use in the United States Pharmacopœia, but without being recognised under a distinct name, being formed as one step of the process adopted in that work for preparing tartar emetic. The name given to this oxide by the Dublin College is very exceptionable. It is not formed on correct chemical principles; neither has it any pharmaceutical convenience to recommend it.

Off. Prep. Antimonii et Potassæ Tartras, *Dub.* B.

ANTIMONII ET POTASSÆ TARTRAS. *U.S.* ANTIMONII ET POTASSÆ TARTRAS sive TARTARUM EMETICUM. *Dub.* ANTIMONIUM TARTÁRIZATUM. *Lond.* TARTRAS ANTIMONII. *Ed.* *Tartrate of Antimony and Potassa. Tartarized Antimony. Emetic Tartar.*

"Take of Prepared Sulphuret of Antimony *two ounces;* Muriatic Acid *twelve ounces and a half:* Nitric Acid *a drachm;* Water *a gallon.* Having mixed the acids together in a glass vessel, add by degrees the Sulphuret of Antimony, and digest the Mixture, with a gradually increasing heat, till effervescence ceases; then boil for an hour. Filter the liquor when it is cold, and pour it into the water. Wash the precipitated powder frequently with water, till it is entirely freed from acid, and then dry it. Take of this powder *two ounces;* Supertartrate of Potassa, in very fine powder, *two ounces and a half;* Distilled Water *eighteen fluidounces.* Boil the Water in a glass vessel; then add the powders, previously mixed together, and boil for half an hour: lastly, filter the liquor through paper, and set it aside to crystallize." *U.S.*

"Take of Nitromuriatic Oxide of Antimony *four parts;* Bitartrate of Potassa, in very fine powder, *five parts;* Distilled Water *thirty-four parts.* Boil the Water in a glass vessel; then gradually throw into it the Oxide and Bitartrate of Potassa, previously mixed, and boil for half an hour; then filter the liquor through paper, and crystallize by slow cooling." *Dub.*

"Take of Glass of Antimony, in very fine powder, Supertartrate of Potassa, each, *a pound;* boiling Distilled Water *a gallon.* Mix the Glass of Antimony and the Supertartrate of Potassa intimately together, and throw the mixture by degrees into the boiling Distilled Water, stirring constantly with a rod. Boil the whole for a quarter of an hour, and set it aside. Filter it when cold, and evaporate the filtered liquor, that crystals may form." *Lond.*

"Take of Sulphuret of Antimony and Nitrate of Potassa *equal weights;* Supertartrate of Potassa *a sufficient quantity.* Powder the Sulphuret and Nitrate separately, and having mixed them thoroughly, throw them into a red-hot crucible. When the deflagration is finished, separate the reddish matter obtained from the white crust, and rub it into a very fine powder, which is to be washed with abundance of warm water, and then dried. Mix this powder, by trituration, with *an equal weight* of Supertartrate of Potassa, and boil the mixture in a glass vessel, with four times its weight of Distilled Water, for an hour; then filter through paper, and evaporate the filtered liquor, so that crystals may form." *Ed.*

This preparation is a double salt, consisting of the tartrate of potassa, united with the tartrate of the sesquioxide of antimony. The principle of its formation is exceedingly simple, being merely the saturation of the excess of acid in the bitartrate of potassa (cream of tartar), with sesquioxide of antimony. The various officinal processes for its preparation all agree in boiling cream of tartar with some form of antimonial sesquioxide, and only differ in the particular one selected, and in some minor details of manipulation. The United States Pharmacopœia, following the Dublin, employs the oxy-chloride, (*nitromuriatic oxide*, Dub.) while the London College uses the *glass of antimony*, and the Edinburgh the *crocus.* The nitromuriatic oxide and glass have been described under other heads, to which the reader is referred for their mode of preparation and properties. (See *Antimonii Oxydum Nitromuriaticum*, and *Antimonii Vitrum.*) In the Edinburgh formula for tartar emetic, the crocus is formed in the first part of the process, and, not being prepared by a separate formula, will be described in this place. It is generated during the deflagration of the sulphuret of antimony and nitrate of potassa. The nitric acid of the nitre is decomposed, and by furnishing oxygen to part of the sulphuret, converts its constituents into sulphuric acid and sesquioxide of antimony. The sulphuric acid then combines with the potassa of the nitre, to form sulphate of potassa, while the sesquioxide unites with the undecomposed portion of the sulphuret, to constitute the crocus. The white crust mentioned in the formula as rejected, consists of the sulphate of potassa formed as above. *Crocus of antimony* is in the form of a liver-brown opaque vitrified mass. When too little nitre has been used in its preparation, it is steel-gray. It consists, according to Proust, of three parts of sesquioxide of antimony, and one of sulphuret; and agrees, therefore, with glass of antimony, in being a mixture of sesquioxide and sulphuret, though containing a smaller proportion of the former.

In the first part of the United States formula, directions are given for procuring the Dublin nitromuriatic oxide of antimony, a preparation not recognised under a distinct name, nor obtained by a separate process, in our national Pharmacopœia. The directions are nearly the same as those of the Dublin College, the acids being employed in the same proportions; but the quantity of sulphuret of antimony is less in the United States process, in the proportion of sixteen to twenty. The latter part of the formula is an exact transcript, as to the quantities taken, of the process of the former Dublin Pharmacopœia, which, with the exception of a slight difference in the amount of water, is adopted in the revision of that work in 1826. Thus the proportions of the United States formula are, nitromuriatic oxide 2 ounces, cream of tartar $2\frac{1}{2}$ ounces, water 18 fluidounces. Now 18 fluidounces of water weigh almost precisely 17 ounces. Substituting this weight, the proportions are as 2, $2\frac{1}{2}$, and 17, or when doubled, 4, 5, and 34, which are the identical numbers used in the Dublin formula. Assuming then the United States and Dublin formulæ as identical, the following table will represent the proportions in which the materials for making tartar emetic are employed in the four Pharmacopœias noticed in this work. The measured portion of water of the London process is converted into its equivalent weight; and the amount of antimonial oxide is assumed at the common quantity of four parts in each formula.

Authority.	Form of Sesquioxide employed.	Proportion of Sesquioxide.	Proportion of Cream of Tartar.	Proportion of Water.
U.S. & Dublin Pharm.	Nitromuriatic oxide.	4	5	34
London Pharm.	Glass.	4	4	40
Edinburgh Pharm.	Crocus.	4	4	32

The U. S. and Dub. Pharmacopœias direct the ebullition to be continued for half an hour, filter the solution while hot, and, without concentration, set it aside to crystallize. The London College boils for a quarter of an hour, and filters the solution when cold. The Edinburgh College boils for an hour, and filters while hot. Both these Colleges evaporate to crystallize.

In judging of the relative eligibility of these processes, several circumstances are to be taken into view; such as the proportions employed, the length of the ebullition, and the relative advantages of the antimonial oxide selected. The cream of tartar ought not to be in excess; as in this case it is apt to crystallize upon cooling with the tartar emetic. To avoid such a result it is better to have a slight excess of antimonial oxide. Upon inspecting the table just given, it would appear that the oxide is most deficient in the U.S. and Dublin formulæ; but in making the comparison, it must be recollected that the nitromuriatic oxide used in them is the sesquioxide of antimony nearly pure; while the glass and crocus contain a considerable quantity of sulphuret. Mr. Phillips, indeed, recommends that the glass in the London formula should be increased one-tenth; while on the other hand, we are assured by Dr. Barker that the proportions of the Dublin (U. S.) formula furnish a slight excess of antimonial oxide. No other rule is applicable to the proportion of the water, except that it should be sufficient to dissolve the tartar emetic formed. The London Pharmacopœia employs the largest quantity of water, and filters when cold; and perhaps it is sufficient, at common temperatures, to retain in solution all the tartar emetic formed. The hot filtration directed by the other Pharmacopœias may be performed conveniently by means of the tin apparatus of Dr. Hare, for filtering liquors at the point of ebullition. (*See p. 692, where this apparatus is figured.*) Here the proportion of water is smaller; and if attention were not paid to preserving the heat of the liquid while filtering, it would be apt to crystallize in the paper. Mr. Phillips very justly objects to the time prescribed for the ebullition in the London process as too short; and an hour, the period directed by the Edinburgh College, is unnecessarily long. Half an hour, the time ordered in the U. S. and Dub. formulæ, is, perhaps, a proper medium. But whenever any of these officinal processes which direct concentration are repeated on a small scale, it is necessary to supply the water which is lost by evaporation; otherwise the liquor will inevitably crystallize in the filter. In all cases, the salt should be obtained in well defined crystals, unmixed with those of cream of tartar, as the best index of its purity. The practice of some manufacturing chemists, therefore, of boiling the filtered liquor to dryness, whereby an impure mass is obtained, consisting in part only of the antimonial salt, is very reprehensible.

Though the glass of antimony will furnish good tartar emetic, yet there are several objections to its use. Thus it always contains as impurity, about five per cent. of silica, and a small portion of peroxide of iron. Besides, it is sometimes mixed with glass of lead, an adulteration which is not easily detected by the eye. Even if it be obtained of good quality, it requires to be finely levigated; or it will only partially unite with the cream of tartar, as was pointed out by Mr. Phillips. The principal objection to the crocus, is that it is not easily obtained in the shops of good quality; and even when properly prepared, as by the formula of the Edinburgh College, it requires to be levigated and elutriated to make it readily unite with the cream of tartar. The use of the nitromuriatic oxide is liable to none of these objections, and to no other, except its expense, which is one of very minor importance, where the purity of so important a medicine as tartar emetic is concerned. The preference is given to it by Berzelius; and M. Henry, an eminent pharmaceutist of Paris, after an elaborate comparison of the different processes, declares in favour of this oxide, as superior to all others for preparing this antimonial salt. The weight of authority being thus in favour of the nitromuriatic oxide, the National Convention, in their last revision of the U. S. Pharmacopœia, acted judiciously in substituting the Dublin formula for tartar emetic, in place of Mr. Phillips's process originally adopted in that work.

The process of Mr. Phillips, here alluded to, consists in boiling one part of subsulphate of antimony with an equal weight of cream of tartar, and six parts of water. The boiling is continued, until the liquid becomes slightly turbid, when it is filtered, evaporated, and set aside to crystallize. The mother waters are twice successively boiled down, and two additional crops of crystals obtained, which, if not white, must be purified by solution and recrystallization. The subsulphate is formed by boiling powdered metallic antimony with twice its weight of sulphuric acid to dryness in an iron vessel, and washing the grayish product with water, until the uncombined sulphuric acid is separated. This substance, though called a subsulphate, is essentially the sesquioxide of antimony, the quantity of acid which it contains not constituting a definite proportion. Good tartar emetic may be obtained by this process, which, according to Mr. Phillips, is very productive. M. Henry, however, objects to it on account of the variable composition of the subsulphate employed.

The process of the Paris Codex coincides with that of the London College, in the employment of the glass; but it is very little followed, as the salt obtained by it requires repeated crystallizations to free it from the tartrates of lime and iron.

It has been already mentioned that M. Henry preferred the use of the nitromuriatic oxide for making tartar emetic; in other words, the Dublin process. He has thought, however, that it was susceptible of some improvements, and has given a process on a large scale, which he prefers. As this formula may be useful to the manufacturing chemist, we subjoin it, turning the French weights into the nearest apothecaries' weights and measures. Take of prepared sulphuret of antimony, in very fine powder, three pounds four ounces: muriatic acid, marking 22° (sp. gr. 1.178), eighteen pounds and a half; nitric acid two ounces and a half. Introduce the sulphuret into a glass matrass, of a capacity double the volume of the mixture to be formed, and add to it from three to five pounds of the acids previously mixed, so that the sulphuret may be thoroughly penetrated by them; then add the remainder of the acids. Place the matrass on a sand-bath, and heat the mixture gradually to ebullition; avoiding the vapours, which are disengaged in large quantity. Continue the heat, until the vapours given off are so far deprived of sulphuretted hydrogen, as not to blacken white paper, moistened with the solution of acetate of lead; after which allow the liquor to cool, and to remain at rest until it has become clear. Decant the clear liquid, and to obtain the portion of it which may be retained by the moist residue, mix this with a small portion of muriatic acid, and again decant. Mix the decanted liquids, which consist of a solution of muriate of antimony, and add them to a large quantity of water, in order that the nitromuriatic oxide may be precipitated; taking care, during their addition, to stir constantly in order that the precipitated powder may be more minutely divided, to facilitate its subsequent washing. To determine whether the water has been sufficient to decompose the whole of the muriate, a part of the supernatant liquid, after the subsidence of the powder, is to be added to a fresh portion of water; and if a precipitate takes place, more water must be added to the mixture, so as to obtain the largest possible quantity of the nitromuriatic oxide. The precipitation being completely effected, wash the powder repeatedly with water, until this no longer affects litmus, and then place it on linen to drain for twenty-four hours. The quantity of nitromuriatic oxide thus obtained will be about three pounds and a half in the moist state, or two pounds nine ounces when dry. Assuming it to be this quantity, mix it with three pounds eleven ounces of cream of tartar, in fine powder, and add the mixture to two gallons and five pints of boiling water, contained in an iron kettle. Concentrate the liquor rapidly until it marks 25° of Baumé's hydrometer for salts, and then filter. By repose, the liquor furnishes a crop of very pure crystals, which require only to be dried. The mother waters are treated in the following manner. Saturate the excess of acid with chalk, filter, and concentrate to 25°. By cooling, a second crop of crystals is obtained; and by proceeding in a similar manner, even a third crop. But the crystals thus obtained are somewhat coloured, and must be purified by recrystallization.

With regard to the above process, it may be observed, that the proportions of the cream of tartar and antimonial oxide must be adjusted according to the numbers given, on the assumption that the latter is dry; but it by no means follows that the whole of the oxide should be dried, which would cause a waste of time. The mode of proceeding is to weigh the whole of the moist oxide, and afterwards to weigh off a small part of it, and to ascertain how much this loses in drying. Then by a calculation it is easy to determine how much of the moist oxide must be taken, to be equivalent to a given quantity of the dry.

Properties. Tartrate of antimony and potassa is a colourless, inodorous salt, possessing a nauseous, styptic taste, and crystallizing usually in rhombic octohedrons. When prepared from the nitromuriatic oxide, it crystallizes in tetrahedrons, and the crystals are often an inch or more in diameter. As it occurs in the shops it is in the form of a white powder, formed by the pulverization of the crystals. The crystals, when exposed to the air, effloresce slightly and become opaque. They are insoluble in alcohol, but soluble in about fourteen times their weight of cold, and twice their weight of boiling water. Dr. Perceval of Dublin, however, asserts that good tartar emetic dissolves in twelve times its weight of cold water. Dr. Barker found that water saturated with this salt at the boiling temperature, would retain more of it when cooled than it is capable of taking up at common temperatures. Its aqueous solution reddens litmus, and undergoes spontaneous decomposition by keeping. Sulphuric, nitric, or muriatic acid, added to its solution, disturbs its transparency, and the alkalies and their carbonates precipitate the sesquioxide of antimony. It is decomposed also by some of the metals and their oxides, by lime-water, muriate of lime, acetate and subacetate of lead, and hydrosulphuric acid and its compounds. The decoctions and infusions of many plants, especially of those which are astringent and contain tannin, such as cinchona, rhubarb, galls, and catechu, precipitate it, with the effect of rendering it nearly or quite inert, and ought not to be associated with it in prescriptions. Other substances, such as tamarind-water, lemonade, whey, &c., decompose it, and give rise to new combinations, which, though not inert, are less active than the original salt.

When tartar emetic is pure, it should exhibit its appropriate crystalline form, and be entirely soluble in water. Its solution should not be precipitated by muriate of baryta, oxalate of ammonia, acidulous nitrate of silver, or acidulous acetate of lead. A precipitate by the first reagent indicates sulphuric acid; by the second, lime; by the third, muriatic acid; and by the fourth, cream of tartar. The most usual impurities which it contains, are uncombined cream of tartar arising either from the use of an excess of this salt in its preparation, or from its fraudulent admixture; tartrate of lime; silica and iron; and sulphate of lime. The tartrate of lime is derived from the cream of tartar, which always contains this impurity. It is liable to form on the surface of the crystals of tartar emetic in crystalline tufts, which are easily brushed off. Silica and iron are apt to be present when glass of antimony has been employed in preparing the antimonial salt, and the evaporation has been carried too far. Sulphate of lime is sometimes an impurity, when tartar emetic has been prepared by means of the subsulphate of antimony. According to Serullas, all the antimonial medicines, except well crystallized tartar emetic, are liable to contain a minute portion of arsenic. The crystalline form of this salt being one of the best tests of its purity, it ought always to be purchased by the apothecary in crystals. It is, indeed, sometimes sold in powder to conceal its imperfections.

Composition. Tartar emetic consists of two equiv. of tartaric acid 132.96, one of potassa 47.15, one of sesquioxide of antimony 153.2, and two of water 18=351.31. It is evident, therefore, that it contains tartaric acid and potassa in the precise proportions to form bitartrate of potassa or cream of tartar; and accordingly, it may be viewed as a compound of one equiv. of cream of tartar, and one of antimonial sesquioxide. The excess of acid in the bitartrate may be considered as saturated by the sesquioxide; and in that view it is a double salt, composed of the tartrate of potassa united with the tartrate of the sesquioxide of antimony. The name, therefore, of the U. S. and Dublin Pharmacopœias is the most correct.

Medical Properties and Uses. Tartrate of potassa and antimony is the most important of the antimonials, and is capable of fulfilling numerous indications in disease. Its general action is that of a sedative upon the circulation; while, on the contrary, it excites most of the secretions. According to the dose in which it is given, and the peculiar circumstances under which it is administered, it acts variously, as an alterative, diaphoretic, diuretic, expectorant, and emetic. In minute doses, it is employed either alone, or conjoined with calomel, with a view to its alterative effects, and has been found useful in diseases of the skin. In small doses, mostly associated with saline remedies, such as nitrate or sulphate of magnesia, and assisted by copious dilution, it is frequently resorted to in febrile complaints, for the purpose of producing perspiration, which is often copiously induced, especially if the remedy creates nausea. If the surface be exposed to cool air, so as to constrict the pores; the tendency will be to the kidneys, with the effect of producing an increased flow of urine. On the principle of exciting the secretions, it proves useful, on many occasions, in pulmonary and bronchial disease as an expectorant; and with a view to its action in this way, it is frequently conjoined with squill, ammoniac, and similar remedies. In full doses, it acts as an emetic, and as such is characterized by certainty, strength, and permanency of operation. It remains longer in the stomach than ipecacuanha, produces more frequent and longer continued efforts to vomit, and exerts a more powerful impression upon the system generally. The nausea and attendant prostration are often very great. As an emetic, its use is indicated where the object is not merely to evacuate the stomach, but to agitate and compress the liver and other abdominal viscera. By the extension of its action to the duodenum, it causes copious discharges of bile, and hence forms an appropriate remedy in those diseases, in which there is an accumulation of that secretion. It is emoloyed as an emetic in the commencement of fevers, especially those of an intermittent or bilious character, in jaundice, hooping cough, and spasmodic croup, and in several diseases of the nervous system, such as mania, amaurosis, tic douleureux, &c. In efforts to reduce old dislocations, its relaxing power is taken advantage of, in order to facilitate the operation. As an incidental effect to its diaphoretic and emetic operation, tartarized antimony often produces purging. Taking advantage of this tendency, practitioners are frequently in the habit of adding it to purgatives, the operation of which it promotes in a remarkable degree. It is contra-indicated in diseases of great debility, in the advanced stages of febrile affections, and in fevers attended with extreme irritability of stomach.

Of late years, on the continent of Europe, tartar emetic has been given in large doses in inflammatory diseases, with a view to its sedative, or, as it is usually termed, *contro-stimulant* operation. This practice originated with Rasori in Italy, and has been followed to a considerable extent in that country and in France. As yet it has had but few imitators in Great Britain or the United States. The chief diseases in which tartar emetic has been thus used are bronchitis, inflammation of the chest, acute rheumatism, chorea, hydrocephalus, and apoplexy. It is directed in doses varying from a grain to two grains and a half every two hours, dissolved in a small quantity of water; the patient being restricted in the use of drinks, whilst under its operation. It is stated, that when the medicine is thus given in diseases of high action, it very seldom produces vomiting, an effect which the authors of the practice wish to avoid. The use of tartar emetic in the doses mentioned is certainly hazardous, and we cannot, therefore, recommend an imitation of the practice. It cannot with propriety supersede the use of blood-letting, which is a safer and more efficient means of reducing inflammation. In cases, however, in which bleeding, both local and general, has been carried as far as the circumstances of the case will safely permit, and inflammatory action continues but partially subdued, the use of tartar emetic, in rather large doses, may sometimes prove useful.

Externally, tartar emetic is sometimes employed as a counter-irritant, mixed with lard or cerate, or sprinkled in very fine powder on adhesive plaster. (See *Unguentum Tartari Emetici*, Dub.) It causes, after a longer or shorter interval, a burning sensation, accompanied by a peculiar and painful pustular eruption. This mode of producing counter-irritation is exceedingly serviceable in a number of diseases; but particularly in deep seated pains, hooping cough, and chronic inflammation of the chest threatening consumption. Care must be taken, when the salt is applied by means of a plaster, that the pustular inflammation does not proceed too far; as in that event, it produces very painful deep seated ulcerations, difficult to heal. It acts by destroying the skin and subjacent cellular tissue in spots, without being absorbed.

Tartar emetic is almost always given in solution, and in an amount which varies with the intention in view in its administration. Its dose as an alterative, is from the sixteenth to the eighth of a grain; as a diaphoretic or expectorant, from an eighth to a sixth of a grain; and as a nauseating sudorific, from a quarter to half a grain; in each case, repeated once every one, two, or four hours. As an emetic, the full dose is from two to three grains, though it is usually given in divided portions of a grain dissolved in a tablespoonful of water, every ten or fifteen minutes until it vomits, the operation being aided by warm water, or warm chamomile tea. It is often conjoined with ipecacuanha, in the proportion of one or two grains to twenty of the vegetable emetic. For convenient administration in small doses, the Pharmacopœias order it dissolved in wine. (See *Vinum Antimonii.*)

Toxicological Properties. The effects produced by a poisonous dose o tartar emetic are an austere metallic taste; nausea; copious vomiting; frequent hickup; burning pain in the stomach; colic; frequent stools; fainting; small, contracted, and accelerated pulse; cold skin; sometimes intense heat; difficult respiration; loss of sense; convulsive movements; very painful cramps in the legs; prostration, and death. To these effects is sometime added difficulty of deglutition. Vomiting and purging do not always tak place; and when they are absent, the other symptoms are aggravated. If the patient has not vomited, immediate recourse must be had to tickling the throat with a feather, and the use of abundance of warm water. The administration of large quantities of oil will sometimes favour vomiting, and may prove useful. If vomiting be not quickly induced, it is necessary to give immediately a large amount of Peruvian bark, mixed with water or in decoction, with a view to decompose the poison. If the bark be not at hand, decoctions of common tea should be administered, until the former can be obtained. Alkaline sulphurets, according to Orfila, augment the irritation of the poison. Nevertheless, the late Dr. Duncan has recorded one case in which the sulphuret of potassa was completely successful. If the vomiting prove excessive, laudanum should be employed either by the mouth or by injection; and to combat the consecutive inflammation which is apt to be excited, bleeding, both local and general, and other antiphlogistic measures, should be resorted to.

VINUM ANTIMONII. *U.S.* VINUM ANTIMONII TARTARIZATI. *Lond.;* VINUM TARTRATIS ANTIMONII. *Ed.* LIQUOR TARTARI EMETICI. *Dub.* *Antimonial Wine.*

"Take of Tartrate of Antimony and Potassa *a scruple;* Wine [Teneriffe] *ten fluidounces.* Dissolve the Tartrate of Antimony and Potassa in the Wine." *U.S.*

The *London* and *Dublin Colleges* direct one scruple of the salt to be dissolved in eight fluidounces of boiling distilled water, and two fluidounces of Rectified Spirit to be added to the solution. By the *Edinburgh* process, twenty-four grains are dissolved in a pound of Sherry wine.

In the revision of the United States Pharmacopœia, the proportion of tartar emetic was altered from four to two grains to the fluidounce of wine; so that our formula now corresponds with that of the British Colleges, and the highly important object has been accomplished, of uniformity in the strength of this very popular preparation. The slight difference between the troy ounce of the Edinburgh formula, and the fluidounce of the others, is scarcely deserving of notice in a practical point of view. The present officinal name was adopted as most convenient, sufficiently expressive, and in accordance with the nomenclature of several other metallic preparations, such as *Ceratum Arsenici, Emplastrum Ferri, Mistura Ferri Composita, &c.*

Difficulty is often experienced in effecting a solution of tartar emetic in wine; and precipitation is very apt to occur after the solution has been effected. These results are attributable either to impurity in the antimonial salt, which frequently contains supertartrate of potassa and various insoluble substances, or to inferiority in the character of the wine, which holds in solution vegetable principles that form insoluble compounds with the oxide of antimony. Dr. Paris states that he has seen the decomposition of the tartar emetic so complete, that no traces of the salt could be detected in the supernatant liquid. The difficulty is not avoided by the plan directed in the old Pharmacopœia, of first dissolving the antimonial in water, and then adding the wine; for even allowing that the solution may be accomplished, the same ingredients are present, and their mutual reaction must ultimately result in the same effects. The proper course is to select perfectly pure crystallized tartar emetic, and sound Teneriffe or Sherry wine, which make a permanent solution. To obviate the risk of decomposition and consequent inequality of strength, the London and Dublin Colleges direct water and rectified spirit in about the proportions in which these exist in the wines just mentioned. The only objection to this menstruum is the want of colour, which renders the preparation liable to be confounded with less active liquids.

The advantages of antimonial wine are, that it affords the means of administering minute doses of tartar emetic, and is more permanent than an aqueous solution of that salt, which is liable to spontaneous decomposition. It is usually administered in small doses as a diaphoretic or expectorant, or as an emetic in infantile cases. Where a considerable quantity of tartar emetic is requisite, it should always be given in extemporaneous aqueous solution. The dose of the wine as an expectorant or diaphoretic, is from ten to thirty drops, given frequently; as an emetic for children, from thirty drops to a fluidrachm, repeated every fifteen minutes till it operates. W.

ANTIMONII SULPHURETUM PRÆPARATUM. *U.S., Dub.*

Sulphuretum Antimonii Præparatum. *Ed. Prepared Sulphuret of Antimony.*

"Take of Sulphuret of Antimony *any quantity*. Prepare it in the manner directed for Carbonate of Lime." *U.S.*

"Powder Sulphuret of Antimony in an iron mortar, levigate it upon a porphyry stone with a little water, and put it into a large vessel. Then pour water on it, and, after frequently agitating the vessel, pour it off, loaded with the fine powder. Allow the water to remain at rest, and when the powder has subsided, dry it. The coarse powder, which the water could not suspend, is to be again levigated, and treated in the same way." *Ed.*

"Take of Sulphuret of Antimony *any quantity*. Reduce it to powder, and separate for use the impalpable particles, in the manner directed for the preparation of Chalk." *Dub.*

Sulphuret of antimony in mass is placed in the Materia Medica of all the Pharmacopœias noticed in this work. But for use in medicine, and for some pharmaceutical processes, it requires to be levigated, and hence the necessity of the above formulæ.

Properties. Prepared sulphuret of antimony is in the form of a dull insoluble powder, without taste or smell; usually of a blackish colour, but, when perfectly pure, reddish-brown. By exposure to air, it absorbs, according to Buchner, a portion of oxygen, and becomes partially converted into sesquioxide. Its usual adulterations and its composition are given under another head. (See *Antimonii Sulphuretum.*)

Medical Properties and Uses. This preparation is very uncertain in its operation; sometimes appearing to be almost inert, and at other times, if it meet with acid in the stomach, acting with extreme violence, producing vomiting and hypercatharsis. The effect usually attributed to it is that of a diaphoretic and alterative; and the diseases in which it is principally recommended, are scrofula, glandular obstructions, cutaneous diseases, and chronic rheumatism. It is very little employed by physicians in the United States, its use in this country being almost exclusively confined to veterinary practice. The dose is from ten to thirty grains, given in powder or bolus.

Off. Prep. Antimonii et Potassæ Tartras, *U.S.;* Antimonii Oxydum Nitromuriaticum, *Dub.;* Antimonii Sulphuretum Præcipitatum, *U. S., Ed., Dub.;* Pulvis Antimonialis, *Dub.* B.

ANTIMONII SULPHURETUM PRÆCIPITATUM. *U. S. Lond.*

Sulphuretum Antimonii Præcipitatum. *Ed.* Sulphur

ANTIMONIATUM FUSCUM. *Dub.* *Precipitated Sulphuret of Antimony.*

"Take of Prepared Sulphuret of Antimony *two pounds;* Solution of Potassa *four pints;* Distilled Water, Diluted Sulphuric Acid, each, *a sufficient quantity.* Mix the Sulphuret of Antimony with the Solution of Potassa, and three pints of Distilled Water, and boil them over a gentle fire for three hours, constantly stirring, and occasionally adding Distilled Water so as to preserve the same measure. Strain the liquor immediately through a double linen cloth, and gradually drop into it, while yet hot, sufficient Diluted Sulphuric Acid to precipitate the powder; then wash away the Sulphate of Potassa with hot water, dry the Precipitated Sulphuret of Antimony, and rub it into a fine powder." *U.S.*

The *London* process is the same as the above; the United States process having been adopted from that of the London College.

"Take of Water of Potassa *four parts;* Water *three parts;* Prepared Sulphuret of Antimony *two parts;* Diluted Sulphuric Acid *a sufficient quantity.* Mix the Sulphuret with the Water of Potassa and the Water; then boil them in a covered iron pot over a gentle fire for three hours, frequently stirring with an iron spatula, and adding water as it may be required. Strain the hot liquor through a double linen cloth, and add to it, when strained, as much of the Acid as may be necessary to precipitate the Sulphuret, which must be well washed with warm water." *Ed.*

"Take of Prepared Sulphuret of Antimony *one part;* Water of Caustic Potassa *eighteen parts;* Diluted Sulphuric Acid *eleven parts*, or *a sufficient quantity.* Add the Sulphuret of Antimony to the Water of Caustic Potassa, and boil for an hour. Strain the hot liquor through a double linen cloth, and drop into it the Diluted Sulphuric Acid. Wash away the Sulphate of Potassa with warm water. Dry the Brown Antimoniated Sulphur, and rub it into fine powder." *Dub.*

As the theory of the formation of the precipitated sulphuret of antimony is intimately connected with that for forming the substances called *kermes mineral*, and *golden sulphur*, we shall first describe the latter substances, as introductory to our account of the former.

Kermes mineral, according to Thenard, may be obtained by three distinct processes—by treating the sesquisulphuret of antimony with a boiling solution of the carbonated alkalies, with a boiling solution of the caustic alkalies, or with the carbonated alkalies at a red heat. These several processes give brown powders, which vary in their shade of colour, and which, though usually considered as identical, differ in composition. The kermes obtained by the first process is an oxysulphuret, that is, a mixture of sesquioxide of antimony with hydrated sesquisulphuret; while the product of the other two is essentially a hydrated sesquisulphuret, though containing occasionally a little oxysulphuret.

In France the process by the use of the carbonated alkalies in solution, is preferred for preparing the kermes; and the alkali selected is soda as giving a handsomer product. The formula of Cluzel is to boil for half an hour one part of pulverized sesquisulphuret of antimony with twenty-two or twenty-three parts of crystallized carbonate of soda, in two hundred and fifty parts of water, to filter the liquor and receive it in warm earthen pans, which must be covered, and allowed to cool slowly; at the end of twenty-four hours, the kermes is deposited. It is then collected on a filter, washed with *boiled* water, cooled without contact of air, dried at the temperature of 77°, and kept in bottles well stopped.

The rationale of the formation of kermes by this process is as follows:—a portion of the carbonate of soda is converted, by a transfer of carbonic acid, into caustic soda and sesquicarbonate. By a double decomposition taking place between a part of the sesquisulphuret of antimony and the caustic soda, sesquioxide of antimony, and sulphuret of sodium are formed. The sesquioxide then dissolves in the solution of carbonate of soda, and the undecomposed portion of the sesquisulphuret in that of the sulphuret of sodium. The sesquioxide and sesquisulphuret, being both more soluble in these menstrua hot than cold, precipitate together as the liquid cools, and constitute this variety of kermes. When thus obtained, the kermes is light, velvety, of a dark reddish-purple colour, brilliant in the sun, and of a crystalline appearance. It consists, according to M. Henri, jun., of sesquisulphuret of antimony 62.5, sesquioxide 27.4, water 10, soda a trace. In consequence of the presence of sesquioxide of antimony in this variety of kermes, it must be far more active than the other kinds which contain little or none of this oxide, and ought, therefore, to be preferred for medical use.

Kermes, when obtained by means of the caustic alkalies, may be formed by boiling for a quarter of an hour, two parts of the sesquisulphuret of antimony with one part of caustic potassa in twenty-five or thirty parts of water, filtering the liquor, and allowing it to cool, whereupon the kermes precipitates. In this process, one portion of the sesquisulphuret, by reacting with a portion of the potassa, gives rise to sesquioxide of antimony and sulphuret of potassium. A second portion dissolves in the sulphuret of potassium formed, and a third forms an insoluble compound with a part of the sesquioxide. The remainder of the sesquioxide unites with the potassa, forming a compound, which, being but sparingly soluble, is only in part dissolved. The filtered liquor, therefore, consists of a solution of this compound in water, and of sesquisulphuret of antimony in sulphuret of potassium. By refrigeration, the sesquisulphuret in a hydrated state falls down, free, or nearly free from sesquioxide, this latter being still held in solution by means of the caustic alkali with which it is united.

Kermes is obtained by the third method, or in the dry way, by rubbing together two parts of sesquisulphuret of antimony and one part of potassa of commerce, fusing the mixture in a crucible by a red heat, and treating the greenish-yellow mass formed with boiling water. On the cooling of the liquor, the kermes is deposited, the rationale of its formation being nearly the same with that for forming the second variety of kermes.

Kermes mineral is an insipid, inodorous powder, of different shades of brown. By the action of air and light it gradually becomes lighter coloured, until at last it attains a yellowish-white tint. It first came into use as a remedy in France about the beginning of the last century. Its mode of preparation was possessed as a secret by a French surgeon named La Ligerie, from whom, in 1720, the recipe was purchased by the French government, and made public.

Golden sulphur is formed by the addition of an acid to the liquor which remains after the precipitation of the kermes. According to the directions of the Paris Codex, acetic acid is employed for this purpose. The liquor, when potassa has been used, is at first a solution principally of sesquisulphuret of antimony in sulphuret of potassium. By the action of the air on the liquor, however, the sulphuret of potassium passes to a higher state of sulphuration; and consequently, the addition of an acid, while it throws down the sesquisulphuret of antimony, will precipitate at the same time the excess of sulphur in the sulphuret of potassium. Agreeably to this explanation, the golden sulphur may be considered as a mixture of hydrated sesquisulphuret of antimony with more or less sulphur. It is in the form of a powder of a golden yellow colour. It may be worth while to mention, that the kermes liquor after the use of the carbonated alkalies gives very little golden sulphur; while the liquors resulting from the two other processes yields it in abundance.

From the explanations above given, the reader is prepared to understand that the method of preparing the precipitated sulphuret of antimony of the United States and British Pharmacopœias, consists of the process for forming the kermes mineral by means of the *caustic alkalies*, combined with the process for golden sulphur; for while the refrigeration of the solution would of itself cause the precipitation of the second variety of kermes, or that which contains little or no antimonial oxide, the sulphuric acid added would throw down more or less of the golden sulphur. This view would make the officinal precipitated sulphuret, a mixture of sesquisulphuret and free sulphur, differing from the *true* golden sulphur, merely in containing less free sulphur. No further explanations are deemed necessary of the formulæ placed at the head of this article.

Properties of the Precipitated Sulphuret. This substance is an orange-coloured, insoluble powder, without smell, and possessing a slightly styptic taste. When heated it readily catches fire, burning with a greenish-blue flame, and giving off sulphurous acid, while the metal remains behind in the state of a grayish oxide. When pure it is not acted on by dilute sulphuric acid; and hence, if it effervesce with this acid, its adulteration with chalk may be suspected. It should readily dissolve in solutions of the caustic fixed alkalies.

Medical Properties. The precipitated sulphuret is diaphoretic or emetic according to the dose. It is, however, an uncertain medicine, as well from the want of uniformity in its composition, as from its liability to vary in its action with the state of the stomach. It is seldom given alone, but generally in combination with calomel and guaiac, in the form of Plummer's pill, as an alterative in secondary syphilis and cutaneous eruptions, or conjoined with henbane or hemlock, in chronic rheumatism. (See *Pilulæ Hydrargyri Submuriatis Compositæ*, Lond.) During its use the patient should abstain from acidulous drinks. Its dose as an alterative is from one to two grains twice a day in the form of pill; as an emetic, from five grains to a scruple. *Kermes* obtained by means of the carbonated alkalies, being a more active preparation, must be used in a smaller dose; while, on the other hand, the *true golden sulphur*, containing a greater excess of sulphur than the precipitated sulphuret, would perhaps require to be given in larger amount.

Off. Prep. Pil. Hydrargyri Submuriatis Comp. *Lond., Ed., Dub.* B.

PULVIS ANTIMONIALIS. *Lond., Dub.* OXIDUM ANTIMONII CUM PHOSPHATE CALCIS. *Ed.* *Antimonial Powder.*

"Take of Sulphuret of Antimony, in powder, *a pound;* Hartshorn shavings *two pounds.* Mix, and throw them into a wide crucible heated to whiteness, and stir them constantly until visible vapour ceases to arise. Rub the residue to powder, and put it into a proper crucible. Then apply heat, and raise it gradually to whiteness, and keep it so for two hours. Rub the residue into a very fine powder." *Lond.*

"Take of Sulphuret of Antimony, in coarse powder, Hartshorn shavings, each, *equal parts.* Mix, and put them into a shallow iron pot, heated to redness, and stir the mixture constantly, until it becomes of an ash-gray colour, and having removed it from the fire, reduce it to powder and put it into a coated crucible. Lute to this crucible another inverted over it, and perforated with a small hole in the bottom, and apply heat, which is to be gradually raised to whiteness, and then kept at that temperature for two hours. Lastly, reduce the matter, when cold, to a very fine powder." *Ed.*

The *Dublin* College uses the proportions of the London; but treats the materials in the manner directed in the Edinburgh formula.

This preparation, which consists of phosphate of lime, or bone-earth, mixed with antimony in an uncertain state of oxidation, is intended to furnish a substitute for the celebrated empyrical remedy of Dr. James, an English physician, after whom the original composition was called *James's powder*. Dr. Pearson, of London, found the genuine powder to consist, on analysis, of phosphate of lime and oxidized antimony; and, guided by his results, devised the formula adopted by the British Colleges for producing an imitation of it. By burning the materials directed in a wide vessel, while they are constantly stirred, the sulphur is expelled in the form of sulphurous acid, and the antimony is oxidized; while the hartshorn, which is of the nature of bone, has the greater part of its animal matter consumed. By the subsequent calcination at a white heat, the remainder of the animal matter is dissipated, leaving only the phosphate of lime mixed with the oxidized antimony. This mixture constitutes the antimonial powder. The only material difference between the processes of the Colleges, is that the London and Dublin use two parts of hartshorn shavings to one of sulphuret; while the Edinburgh College employs equal parts which are also the proportions adopted in the Paris Codex. The use of the larger proportion of hartshorn is stated to obviate the inconvenience of the vitrification of part of the antimony; but Dr. Duncan alleges that the product thus obtained does not correspond so nearly with James's powder, as analyzed by Dr. Pearson, as when the smaller proportion is employed.

In consequence of the variable nature of antimonial powder, as obtained in the processes of the Colleges by the agency of fire, Mr. Chenevix proposed to form it in the humid way, by dissolving equal weights of nitromuriatic oxide of antimony and precipitated phosphate of lime, in the smallest possible quantity of muriatic acid, and precipitating this solution by adding it to diluted water of ammonia. The solvent power of the muriatic acid being destroyed by the ammonia, the precipitate will be an intimate mixture, in determinate proportions, of sesquioxide of antimony and phosphate of lime. This precipitate, Mr. Chenevix states, is soluble in any acid capable of dissolving its constituents separately. On the other hand, 28 per cent. of James's powder, and about 44 per cent. of the London antimonial powder resist the action of all acids. It is hence evident that Mr. Chenevix's powder would prove far more active than those for which it is proposed as a substitute. This objection to it might be obviated by increasing the proportion of phosphate of lime; but still it is liable to the inconvenience, according to Mr. Brande, of becoming horny or gritty, and difficult to powder.

Properties, &c. Antimonial powder has a dull-white colour, is tasteless and inodorous, and insoluble in water. It is only partially soluble in acids; the phosphate of lime, and any sesquioxide of antimony present being dissolved, and a variable amount of antimonious acid (deutoxide of antimony) remaining behind. Its activity as a medicine will depend upon the proportion of sesquioxide present, the quantity of which may be judged of by dropping the muriatic solution obtained from the preparation into water, whereby the sesquioxide will be precipitated. Its composition varies exceedingly, a circumstance which is a strong objection to it as a medicine. Mr. Phillips analyzed two specimens, and found one to contain 35, the other 38 per cent. of oxidized antimony, the remainder being phosphate of lime. Mr. Brande has generally obtained a greater discordance of results, and occasionally detected as much as 5 per cent. of sesquioxide. From the James's powder, both Dr. Pearson and Mr. Phillips obtained from 56 to 57 per cent. of oxidized antimony. A portion of this powder, derived from the heirs of Dr. James, was found by Berzelius to contain nearly two-thirds antimonious acid, one-third phosphate of lime, and scarcely one per cent. of antimonite of lime soluble in water. Phillips and Brande speak of the antimony as being in the state of *peroxide* (antimonic acid); but it can be shown that it must be in the state of *deutoxide*, or antimonious acid, as stated by Berzelius, if the preparation be made according to the directions of the Colleges. This is evident from the circumstance, that the high heat to which the preparation is exposed would decompose the peroxide, and is compatible only with the existence of the deutoxide. When antimonial powder, therefore, contains sesquioxide, in which case only it is active, its presence must arise from the materials having been exposed to a lower heat than that directed by the Colleges.

Medical Properties and Uses. This preparation is stated to be alterative, diaphoretic, purgative, or emetic, according to the dose in which it may be given. Until within a few years it was very much used in febrile diseases, with a view to its diaphoretic effect. According to Dr. A. T. Thomson, it is advantageously given in acute rheumatism, conjoined with camphor, calomel, and opium, and with calomel and guaiac in several cutaneous affections. The estimation in which this preparation is held is very various. The late Dr. Duncan characterizes it as one of the best antimonials we possess; yet he acknowledges that its effects vary very much, either from idiosyncrasy, or variations in its composition. Dr. Thomson found it sometimes to answer his expectations, but as often to disappoint them. Mr. Brande admits its activity sometimes, and entire inertness at others, differences which he attributes to the presence or absence of *sesquioxide* of antimony. Upon the whole, it appears evident, that, whatever may be the occasional efficacy of this medicine, it is too variable in its composition, from circumstances in its preparation scarcely within the control of the pharmaceutical chemist, to make it a safe remedy. No therapeutical effect can be expected from it, which cannot be more certainly and safely produced by tartar emetic; and it seems to be the sentiment of some of the best practitioners, that this antimonial may in all cases be advantageously substituted for it. Considerations of this kind, no doubt, influenced the United States Medical Convention, in omitting it from our Pharmacopœia of 1830.

The dose of antimonial powder as a diaphoretic, is from three to eight grains every third or fourth hour, given in the form of pill. In larger doses it is purgative or emetic. It is impossible, however, to give precise directions as to the dose; as it sometimes proves virulently emetic, and at other times is without any obvious effect, even in doses of 100 grains. B.

AQUA.

Water.

AQUA DESTILLATA. *U.S., Lond., Ed.* AQUA DISTILLATA. *Dub.* *Distilled Water.*

"Take of Water *ten gallons.* First distil four pints, and throw them away; then distil four gallons. Keep the Distilled Water in a glass bottle." *U.S., Lond.*

"Let Water be distilled in appropriate and very clean vessels, until about two-thirds have come over." *Ed.*

"Take of Water *twenty pounds.* Put it into a glass retort, and having rejected the first pound which comes over, distil a gallon with a moderate heat." *Dub.*

The purest natural water is not sufficiently pure for some pharmaceutical purposes; and hence the necessity of the above processes for its distillation. It is best to reject the first portion which comes over, as this may contain carbonic acid and other volatile impurities, and the last portions of the water ought not to be distilled, lest it should pass over in an empyreumatic state. The Dublin College directs the distillation to be conducted in a glass retort; but it is usually performed with the ordinary still and condenser, and such an apparatus is evidently contemplated in the United States and London formula. Mr. Brande states that distilled water often derives from the still a foreign flavour, which it is difficult to avoid. He therefore recommends that a still and condenser be exclusively kept for distilling water; or, where this cannot be done, that steam be driven through the condensing pipe for half an hour, for the purpose of washing it out before it is used; the worm-tub having been previously emptied.

Properties, &c. Distilled water, as usually obtained, has always a vapid and disagreeable taste. It is not perfectly pure; water, to be so, requiring to be distilled in silver vessels. The properties of pure water have already been given under the head of *Aqua.* Distilled water should undergo no change on the addition of tincture of soap, subacetate of lead, nitrate of baryta, oxalate of ammonia, nitrate of silver, or lime-water. It is uselessly employed in some formulæ; but is essentially necessary in others. As a general rule, when small quantities of active remedies are to be given in solution, and in the preparation of collyria, distilled water should be employed. The following list contains the chief substances which require distilled water as a solvent;—tartar emetic, corrosive sublimate, nitrate of silver, muriate of baryta, acetate of lead, the sulphates of iron and zinc, sulphate of quinia, and sulphate and acetate of morphia. B.

◆

AQUÆ MEDICATÆ. *U.S.*

Medicated Waters.

Under this head are included, in the United States Pharmacopœia, all those preparations consisting of water impregnated with some medicinal substance, which are not arranged in any other class. Among them are the Distilled Waters of the British Pharmacopœias, which therefore require some notice in the present place.

Aquæ Destillatæ. *Lond.* Aquæ Stillatitiæ. *Ed.* Aquæ Distillatæ. *Dub.* Many vegetables impart to water distilled from them their peculiar flavour, and more or less of the medical properties by which they are distinguished. The distilled waters chiefly used, are those prepared from aromatic plants, the volatile oil of which rises with the aqueous vapour, and is condensed with it in the receiver. But as water is capable of holding but a small proportion of the oil in solution, these preparations are generally feeble, and are employed rather as pleasant vehicles or corrigents of other medicines, than with a view to any remediate action of their own.

In the preparation of the distilled waters, the London College directs the dried plants, because the fresh are not to be had at all seasons; but the latter, at least in the instances of herbs and flowers, should be preferred if attainable. Flowers which lose their odour by desiccation, may be preserved by incorporating them intimately with one-third of their weight of common salt; and in this state, according to M. Decroizilles, afford distilled waters of very delicate flavour.

It is necessary to observe certain practical rules in conducting the process of distillation. When the substance employed is dry, hard, and fibrous, it should be mechanically divided, and macerated in water for a short time previously to the operation. The quantity of materials should not bear too large a proportion to the capacity of the alembic, as the water might otherwise boil over into the receiver. The water should be brought quickly to the state of ebullition, and continued in that state till the end of the process. Care should be taken to leave sufficient water undistilled to cover the whole of the vegetable matter, lest a portion of the latter, coming in contact with the sides of the vessel, might be decomposed by the heat, and yield empyreumatic products. If any volatile oil float upon the surface of the distilled water, it should be separated.

But however carefully the process may be conducted, the distilled waters prepared from plants always have at first an unpleasant smoky odour. To free them from this, it is necessary to expose them for a short time to the air, before enclosing them in well stopped bottles, in which they should be ultimately preserved. When long kept they are apt to form a viscid ropy matter, and to become sour. This result is ascribable to other principles, which rise with the oil in distillation, and promote its decomposition. To prevent this decomposition, the *London College* orders the addition of five fluidounces of proof spirit to a gallon of the distilled water; the *Edinburgh*, five ounces of diluted alcohol to ten pounds; and the *Dublin*, half an ounce of rectified spirit to a pound. But this addition is inadequate to the intended object. A better plan is to redistil the waters; as, when thus purified, it is said that they may be kept for several years unchanged.

Another mode of preparing the distilled waters, is to substitute the volatile oil, previously separated from the plant, for the plant itself in the process. This mode is directed by the London and Dublin Colleges in several instances. It is preferable to the preceding, as it affords a purer and more permanent product.

In relation to most of the aromatics, the United States Pharmacopœia discards altogether the process by distillation, and directs that water should be impregnated with the volatile oil by trituration with magnesia, and subsequent filtration. This is by far the most simple and easy process; and the resulting preparation is in all respects equal to that obtained by distillation from the oil. The aromatic solution is pure and permanent, and, notwithstanding the assertion of Dr. Paris to the contrary, is perfectly transparent, the magnesia being separated by the filtration. The carbonate of magnesia, however, should be employed in preference to the pure earth; as the latter sometimes gives a brownish colour to the liquid, and requires to be used in larger proportion. A minute quantity, moreover, of the magnesia is dissolved, and attracting carbonic acid from the air, becomes a carbonate, and is precipitated in a flocculent form. The object of the magnesia or its carbonate is simply to enable the oil to be brought to a state of minute division, and thus presented with a larger surface to the action of the solvent. Chalk and sugar answer a similar purpose; but the latter, by being dissolved with the oil, renders the preparation impure. W.

AQUA ACIDI CARBONICI. *U.S.* *Carbonic Acid Water. Artificial Seltzer Water.*

"By means of a forcing pump, throw into a suitable receiver, nearly filled with Water, a quantity of Carbonic Acid equal to five times the bulk of the Water.

"Carbonic Acid is obtained from the Hard Carbonate of Lime, by means of dilute Sulphuric Acid." *U.S.*

This preparation, which is not adopted by the British Colleges, consists of water highly charged with carbonic acid. Water is found to take up its volume of this acid under the pressure of the atmosphere; and Dr. Henry ascertained, from numerous experiments, that precisely the same *volume* of the *compressed* gas is absorbed under a higher pressure. From this law, the bulk taken up is constant, the quantity being different in proportion as there is more or less driven into a given space. As the space occupied by a gas is inversely as the compressing force, it follows that the quantity of the acid forced into the water will be directly as the pressure. A double pressure will force a double quantity into a given space, and, therefore, cause a double quantity to be absorbed; a treble pressure will drive a treble quantity into the same space, and cause its absorption; and so on for higher pressures, the *bulk* of the *compressed* gas absorbed always remaining the same. From the principles above laid down, it follows, that to saturate water with five times its volume of carbonic acid, as directed in the formula, it must be subjected to a pressure of five atmospheres. This is about the strength of the carbonic acid water manufactured in the United States.

Carbonic acid water is familiarly called in this country "mineral water," and "soda water;" the latter name, originally applied to the preparation when it contained a small portion of carbonate of soda, being from habit continued since the alkali has been omitted. As it is largely consumed, both as an agreeable beverage and as a medicine, it will be proper to give a sketch of the apparatus usually employed in its preparation. This consists of a generator, gasometer, forcing pump, reservoir or fountain, and refrigerator. The generator is usually formed of a wooden tub somewhat like a churn, into which the dilute sulphuric acid is put. On this is luted a small cylindrical wooden vessel, through the bottom of which passes a wooden stirrer. This vessel is filled with marble powder, which, by the movement of the stirrer, is made gradually to fall into the acid below, generating the carbonic acid, which by a lead pipe is conducted into the gasometer. This is a large cylindrical tub, in which another is inverted suspended by a pulley. As soon as the gasometer is full, which should have five or six times the capacity of the reservoir, the operation of condensing the gas into the latter is commenced. This is effected by a condensing pump, the chamber of which is made to communicate, by leaden tubes on opposite sides, with the gasometer and reservoir. The latter, usually called the fountain, is a very strong cylindrica copper vessel, with hemispherical extremities, tinned on the inside, and, before receiving the carbonic acid, nearly filled with water. When the water has been duly charged with the acid gas, it is drawn off as it is wanted, by means of a stop-cock connected with a tube which passes to the bottom of the reservoir. The tube may be of any desired length, so as to draw off the water at a distance from the reservoir. The apparatus is usually placed in the cellar, and the tube from the reservoir is made to pass through the floor and counter of the shop, and terminate in a stop-cock, by means of which the carbonic acid water may be drawn off at pleasure. In order to have the liquid cool in summer, the tube from the cellar generally terminates in a strong metallic vessel of convenient shape, placed under the counter and surrounded with ice, and from this vessel the tube penetrating the counter proceeds.

The acid gas for the impregnation of the water is always obtained from marble dust by the action of sulphuric acid; these being the cheapest materials for the purpose. Chalk may also be used, but is objectionable on account of its communicatiug an unpleasant smell to the carbonic acid. When sulphuric acid is employed, sulphate of lime is formed, which interferes with the action of the acid; and hence it is necessary to stir the mixture to render the decomposition of the carbonate complete.

Properties. Carbonic acid water is a sparkling liquid, possessing an agreeable, pungent, acidulous taste. It reddens litmus feebly, and is precipitated by lime-water. Being impregnated with the acid gas under the influence of pressure, it effervesces strongly when freed from restraint. Hence, to preserve its briskness, it should be kept in strong well corked bottles, placed inverted in a cool place. Several natural waters are of a similar nature; such as those of Seltzer, Spa, and Pyrmont; but the artificial preparation has the advantage of a stronger impregnation with the acid gas. Carbonic acid water should be made with every precaution to avoid metallic impurity. Hence the necessity of having the reservoir or fountain well tinned on the inner surface. Even with this precaution, a slight metallic impregnation is not always avoided, especially in the winter season, when the water is less consumed as a drink, and, therefore, allowed to remain longer in the reservoir. Glass fountains are sometimes used with advantage in this season; and a patent has been taken out for a stoneware fountain enclosed in tinned copper, which has been found to answer a good purpose. When leaden tubes are employed to convey the water, it is liable to be contaminated with this metal, which renders it deleterious. A case of colica pictonum came under the care of one of our medical friends, arising from the daily use of the first draught of carbonic acid water from a fountain furnished with tubes of lead. Tin tubes are sometimes employed, enclosed in lead ones to give them strength.

Carbonic acid, formerly called *fixed air*, is a colourless gas, of a slightly pungent odour and acid taste. It reddens litmus feebly, and combines with salifiable bases, forming salts called carbonates, from which it is expelled by all the strong acids. It extinguishes flame, and is quickly fatal to animals when respired. All kinds of fermented liquors, which are brisk or sparkling, such as champagne, cider, porter, &c., owe these properties to its presence. Its sp. gr. is 1.52. It is composed of one equiv. of carbon 6.12, and two of oxygen 16=22.12.

Medical Properties and Uses. Carbonic acid water is diaphoretic, diuretic, and anti-emetic. It forms a very grateful drink to febrile patients, allaying thirst, lessening nausea and gastric distress, and promoting the secretion of urine. The quantity taken need only be regulated by the reasonable wishes of the patient. It also forms a very convenient vehicle for the administration of magnesia, the carbonated alkalies, sulphate of magnesia, and the saline cathartics generally; rendering these medicines less unpleasant to the palate, and, in irritable states of the stomach, increasing the chances of their being retained. When used for this purpose, six or eight fluidounces will be sufficient. B.

AQUA ANETHI. *Lond.* *Dill Water.*

"Take of Dill Seeds, bruised, *a pound.* Pour on them so much water, that, after the distillation, sufficient may remain to prevent empyreuma. Distil *a gallon.*" *Lond.*

This is seldom if ever used in the United States. W.

AQUA AURANTII CORTICIS. *U.S.* AQUA CITRI AURANTII. *Ed.* *Water of Orange Peel.*

"Take of Fresh Orange Peel *two pounds;* Water *a sufficient quantity;* Diluted Alcohol *four fluidounces.* Pour upon the Orange Peel so much Water, that, after the distillation, sufficient may remain to prevent empyreuma. Then distil a gallon, and add the Diluted Alcohol." *U.S.*

The *Edinburgh College* directs ten pounds of the Water to be distilled from two pounds of the Peel. W.

AQUA CAMPHORÆ. *U.S.* MISTURA CAMPHORÆ. *Lond., Dub.* EMULSIO CAMPHORÆ. *Ed.* *Camphor Water.*

"Take of Camphor *two drachms;* Alcohol *forty minims;* Magnesia *a drachm;* Distilled Water *two pints.* Rub the Camphor first with the Alcohol, afterwards with the Magnesia, and lastly with the Water gradually added; then filter through paper." *U.S.*

The *London College* directs half a drachm of camphor, ten minims of alcohol, and a pint of water, without magnesia. The *Dublin College* orders a scruple of camphor, ten drops of alcohol, a pint of warm water, and instead of the magnesia, half an ounce of sugar. The process in each case is completed as in the United States Pharmacopœia. The *Edinburgh College* directs a scruple of camphor and half an ounce of sugar, well rubbed together, to be beat with half an ounce of blanched sweet almonds, a pound and a half of water to be gradually added, and the mixture to be strained.

In all these processes the object is to effect a solution of the camphor. Water is capable of dissolving but a small proportion of this principle; but the quantity varies with the method employed. Prepared according to the London process, one pint of the water contains only thirteen grains of camphor; according to those of Edinburgh and Dublin less than twenty grains; while our own officinal preparation contains about fifty grains to the pint, or more than three grains to the fluidounce. (*Journ. of the Phil. Col. of Pharm.* iv. 13.) The difference is attributable to the minute division effected in the camphor by trituration with the magnesia, which is afterwards separated by filtration. The use of the alcohol is simply to break down the cohesion of the camphor, and enable it to be more easily pulverized. The process of the United States Pharmacopœia is much preferable to the others, as it affords a permanent solution of sufficient strength to be employed with a view to the influence of the camphor on the system, while the British preparations have little more than the flavour of the narcotic, and are fit only for vehicles of other medicines. The camphor is separated by a solution of pure potassa, and according to Dr. Paris, by sulphate of magnesia and several other salts.

Camphor water is chiefly employed in low fevers and typhoid diseases attended with restlessness, slight delirium, or other symptoms of nervous derangement or debility. It has this advantage over camphor in substance, that the latter is with difficulty dissolved by the liquors of the stomach; but it is not applicable to cases where very large doses of the medicine are required. It is usually given in the dose of one or two tablespoonfuls repeated every hour or two hours. W.

AQUA CARUI. *Lond., Dub.* *Caraway Water.*

"Take of Caraway Seeds, bruised, *a pound.* Pour on them so much Water, that, after the distillation, sufficient may remain to prevent empyreuma. Distil *a gallon.*" *Lond.*

The proportions of the *Dublin College* are the same.

Caraway water has the flavour and pungency of the seeds, but is not used in this country. W.

AQUA CHLORINII. *Dub.* *Chlorine Water.*

"Take of dried Muriate of Soda *one hundred parts;* Oxide of Manganese *thirty parts;* Sulphuric Acid *eighty-seven parts;* Water *one hundred and twenty-four parts.* Add the Acid gradually to the Water, and when the mixture has grown cold, pour it on the Muriate of Soda and Oxide of Manganese, reduced to fine powder, well mixed, and put into a retort. Then with a proper apparatus and a moderate heat gradually increased, transmit the gas escaping from the mixture through two hundred parts of Distilled Water; the operation being concluded as soon as the effervescence in the retort has ceased. Chlorine Water should be kept in well stopped glass bottles, and in a place impervious to the rays of light." *Dub.*

This formula is intended to furnish a saturated solution of chlorine in water. The materials employed are those usually taken for generating chlorine; and this, as it is extricated in a gaseous state, is passed into a portion of water, with a view to its being absorbed. The muriate of soda of the formula is the chloride of sodium of modern chemists. This, when acted on by dilute sulphuric acid and peroxide of manganese, is decomposed, the chlorine is extricated, and the sodium and peroxide of manganese, having been converted, by a transfer of oxygen from the latter to the former, into soda and protoxide, unite with the sulphuric acid, and form sulphate of soda and protosulphate of manganese, which remain behind. The water intended to receive the gas is most conveniently placed in a series of Wolfe's bottles, the last of which should contain some slaked lime, to absorb any excess of chlorine, which might otherwise produce inconvenience by its escape.

Properties. Chlorine water has a yellowish-green colour, a harsh styptic taste, and the peculiar odour of the gas which it contains. Like gaseous chlorine, it destroys all vegetable colours. When cooled to about the freezing point, it forms deep-yellow crystalline plates, consisting of hydrate of chlorine. At the temperature of 50° it contains about twice its volume of the gas. It is decomposed by light, with the production of muriatic acid, and the evolution of oxygen. It is on this account that it requires to be kept in a dark place.

Chlorine is an elementary gaseous fluid, of a greenish-yellow colour, and characteristic and disagreeable smell and taste. Its sp. gr. is 2.47, and its equivalent number 35.42. It is a supporter of combustion, but destructive of life in respiration. When the attempt is made to breathe it, even much diluted, it excites cough and a sense of suffocation, and causes a discharge from the nostrils resembling coryza. When breathed in considerable quantities, it produces spitting of blood, violent pains, and death. It is the agent almost exclusively employed in bleaching and in disinfecting operations.

Medical Properties and Uses. Chlorine water is stimulant and antiseptic.

It is highly esteemed by some practitioners, but as yet is very little employed. It has been used in typhus, and chronic affections of the liver, but the diseases in which it has been most extolled are scarlatina and malignant sore-throat. Externally, it may be used, duly diluted, as a gargle in putrid sore-throat, as a wash for ill-conditioned ulcers and cancerous sores, and as a local bath in diseases of the liver; though for the latter purpose, the nitro-muriatic acid, which is in effect a solution of chlorine, is usually employed. As it depends upon chlorine for its activity, its medical properties coincide generally with those of *chloride of lime*, *chloride of soda*, and *nitromuriatic acid*, to which articles the reader is referred. The dose of chlorine water is from one to two fluidrachms, diluted with eight fluidounces of water, and given in the course of the day. B.

AQUA CINNAMOMI. *U.S., Lond., Dub.* AQUA LAURI CINNAMOMI. *Ed.* *Cinnamon Water.*

"Take of Oil of Cinnamon *half a fluidrachm;* Magnesia *half a drachm;* Distilled Water *two pints.* Rub the Oil of Cinnamon first with the Magnesia, then with the Water gradually added, and filter through paper." *U.S.*

"Take of Cinnamon Bark, bruised, *a pound;* or Oil of Cinnamon, by weight, *five scruples.* Pour so much water on the oil, or on the bark, previously macerated in water for twenty-four hours, that, after the distillation, sufficient may remain to prevent empyreuma. Distil *a gallon.*" *Lond.*

The process of the *Dublin College* is the same with the preceding, except that three drachms of the oil are directed instead of five scruples. The *Edinburgh College* orders ten pounds of water to be distilled from a pound of the bark.

Of these processes, that of the United States Pharmacopœia is decidedly preferable, as much easier than the others, and affording a product in every respect equal, if not superior. Carbonate of magnesia, however, should be used instead of the pure earth, as the latter, in the quantity indicated, forms a semifluid mass with the oil, which is with some difficulty miscible with the water; and, though this disadvantage might be obviated by increasing the quantity of the magnesia, still the objection remains that the preparation is apt to have a brownish colour, which is not produced by the carbonate. Besides, a minute proportion of magnesia is dissolved, sufficient to render the preparation incompatible with small quantities of the sulphates of morphia and quinia, for which it is sometimes employed as a menstruum.

Cinnamon water is a favourite vehicle with many practitioners for other less pleasant medicines; but should be used cautiously in inflammatory affections. For ordinary purposes it is sufficiently strong when diluted with an equal measure of water.

Off. Prep. Mistura Calcis Carbonatis, *U.S.;* Mistura Guaiaci, *Lond.* W.

AQUA LAURI CASSIÆ. *Ed.* *Water of Cassia.*

This is prepared from the variety of cinnamon called cassia, in the manner directed by the Edinburgh College for cinnamon water. The distinction is not recognised in our Pharmacopœia. W.

AQUA CITRI MEDICÆ. *Ed.* *Water of Lemon Peel.*

The *Edinburgh College* directs ten pounds of water to be distilled from two pounds of the fresh peel duly macerated; sufficient water being left to prevent empyreuma. The preparation is almost unknown in this country. W.

AQUA FŒNICULI. *Lond., Dub.* *Fennel Water.*

"Take of Fennel seeds, bruised, *a pound.* Pour on them so much water that, after the distillation, sufficient may remain to prevent empyreuma. Distil *a gallon.*" *Lond.*

The proportions of the *Dublin College* are the same.

Fennel water is seldom used, as the infusion answers a better purpose.
W.

AQUA LAURO-CERASI. *Dub.* *Water of Cherry Laurel.*

"Take of Fresh Leaves of Cherry Laurel *a pound;* Water *three pints.* Distil *a pint*, and instead of Rectified Spirit, add of Compound Spirit of Lavender *an ounce.*" *Dub.*

The substitution of the compound spirit of lavender for alcohol, is in order to impart colour to the preparation, and thus prevent it from being mistaken for common water. It is employed in Europe as a sedative narcotic, identical in its properties with a dilute solution of hydrocyanic acid. The dose is from thirty minims to a fluidrachm.
W.

AQUA MENTHÆ PIPERITÆ. *U.S., Lond., Ed., Dub.* *Peppermint Water.*

This is prepared, according to the United States Pharmacopœia, from the oil of peppermint, in the manner directed for cinnamon water; but the caution should in this instance also be observed, of substituting the carbonate of magnesia for pure magnesia.

"Take of Peppermint, dried, *a pound and a half*, or Oil of Peppermint, by weight, *three drachms.* Pour on the herb or the oil so much water, that, after the distillation, sufficient may remain to prevent empyreuma. Distil *a gallon.*" When the fresh herb is used the quantity should be doubled. *Lond.*

The *Edinburgh College* distils ten pounds of the water from three pounds of peppermint. The *Dublin* process is essentially the same with the London.
W.

AQUA MENTHÆ VIRIDIS. *U.S., Lond., Ed., Dub.* *Spearmint Water.*

This is prepared, according to the United States Pharmacopœia, from the oil of spearmint, in the manner directed for cinnamon and peppermint waters.

By the British Colleges it is also prepared in the manner directed by them for peppermint water.

The two mint waters are among the most grateful and most employed of this class of preparations. Together with cinnamon water, they are used in this country, almost to the exclusion of all others, as the vehicle of medicines given in the form of mixture. They serve not only to conceal or qualify the taste of other medicines, but also to counteract their nauseating properties. The peppermint water is generally thought to have a more pleasant flavour than that of spearmint, but some prefer the latter. Their effects are the same.
W.

AQUA PICIS LIQUIDÆ. *Dub.* *Tar Water.*

"Take of Tar *two pints;* Water *a gallon.* Mix, stirring with a wooden rod for fifteen minutes; then, after the Tar shall have subsided, strain the liquor, and keep it in well stopped bottles." *Dub.*

Water takes from tar a small portion of acetic acid, empyreumatic oil, and resinous matter, acquiring a sharp empyreumatic taste, and the colour of Madeira wine. Thus impregnated it is stimulant and diuretic; and, though at present little used, was formerly highly extolled as a remedy in pulmonary consumption. It may be given with occasional advantage in chronic catarrhal affections, and complaints of the urinary passages. From one to two pints may be taken in the course of the day. W.

AQUA PIMENTÆ. *Lond., Dub.* AQUA MYRTI PIMENTÆ. *Ed.* *Pimento Water.*

"Take of Pimento, bruised, *half a pound;* Water *a pint.* Macerate the berries in the Water for twenty-four hours; then add so much Water, that, after the distillation, sufficient may remain to prevent empyreuma. Distil *a gallon.*" *Lond.*

The *Edinburgh College* distils ten pounds. The *Dublin* process is essentially the same with the London.

Pimento water is brownish when first distilled, and upon standing deposites a brown resinous sediment. It is used as a carminative. W.

AQUA PULEGII. *Lond., Dub.* AQUA MENTHÆ PULEGII. *Ed.* *Pennyroyal Water.*

This is prepared from the European pennyroyal or its oil, precisely in the manner directed by the British Colleges for peppermint water. It is not used in this country, as we have not the plant. A water prepared from the *Hedeoma pulegioides*, or American pennyroyal, might be substituted.

Pennyroyal water is employed for the same purposes as those of peppermint and spearmint.

Off. Prep. Mistura Ammoniaci, *Dub.;* Mistura Assæfœtida, *Dub.* W.

AQUA ROSÆ. *U.S., Lond., Dub.* AQUA ROSÆ CENTIFOLIÆ. *Ed.* *Rose Water.*

"Take of Fresh Hundred-leaved Roses *six pounds;* Water *a sufficient quantity;* Diluted Alcohol *four fluidounces.* Pour on the Roses so much Water, that, after the distillation, sufficient may remain to prevent empyreuma. Then distil *a gallon*, and add the Diluted Alcohol." *U.S.*

The *London* and *Dublin Colleges* order a gallon of the Water to be distilled from eight pounds of the petals; the *Edinburgh*, ten pounds of the Water from six pounds of the petals.

It should be observed, that in the nomenclature of the United States Pharmacopœia, the term "Roses" implies only the petals of the flower. These are directed in the recent state; but it is said that when preserved by being incorporated with one-third of their weight of common salt, they retain their odour, and afford a Water equally fragrant with that prepared from the fresh flower.

Rose water, when properly prepared, has the delightful perfume of the rose in great perfection. It is most successfully made on a large scale. Like the other distilled waters it is liable to spoil when kept; and the alcohol which is added to preserve it is incompatible with some of the purposes to which the water is applied. It is best, therefore, to avoid this addition, and to substitute a second distillation. This distilled water is chiefly employed on account of its pleasant odour in collyria and other lotions. It is wholly destitute of irritating properties, unless when it contains alcohol.

Off. Prep. Mistura Ferri Composita, *U.S., Lond., Dub.;* Mistura Moschi, *Lond.;* Unguentum Aquæ Rosæ, *U.S.* W.

ARGENTUM.

Preparations of Silver.

ARGENTI NITRAS. *U.S., Lond.* NITRAS ARGENTI. *Ed.* ARGENTI NITRAS FUSUM. *Dub.* *Nitrate of Silver.* *Lunar Caustic.*

"Take of Silver, flattened into plates and cut, *an ounce;* Nitric Acid *five fluidrachms* [a fluidounce, *Lond.*]; Distilled Water *two fluidounces.* Mix the Acid with the Water, and dissolve the Silver in the mixture, on a sand-bath. Then gradually increase the heat, so that the Nitrate of Silver may be dried. Melt this in a crucible over a gentle fire, and continue the heat till ebullition ceases; then immediately pour it into suitable moulds. Lastly, wrap it in white paper, and keep it in a well stopped bottle." *U.S.*

The *London* formula differs from the preceding only in the proportion of nitric acid employed, as above indicated, and in omitting to give any directions for wrapping the salt in white paper, and for preserving it in bottles.

"Take of purest Silver, flattened into plates and cut in pieces, *one part;* Diluted Nitrous Acid *two parts;* Distilled Water *one part.* Dissolve the Silver in the Acid and Water, previously mixed, in a matrass, with a gentle heat, and evaporate the solution to dryness. Then put the mass into a large crucible, and place it on the fire, which should at first be moderate, and afterwards increased by degrees until the mass flows like oil; then pour it into iron moulds previously heated and anointed with tallow. Lastly, keep it in a glass vessel very well corked." *Ed.*

"Dissolve Silver in Diluted Nitric Acid [in the manner described under *Crystals of Nitrate of Silver*]; then evaporate the solution to dryness. Melt the residuum, placed in a crucible, over a slow fire; then pour it out into proper moulds, and keep it in a glass phial." *Dub.*

During the solution of silver in nitric acid, part of the acid is decomposed into nitric oxide which is given off and becomes red fumes by contact with the atmosphere, and oxygen which oxidizes the silver. The oxide formed then combines with the remainder of the acid, and generates the nitrate of silver in solution. The water is next driven off by heat, and the salt fused and cast into little cylinders about the size of a quill. The silver should be pure, and the acid diluted for the purpose of promoting its action. The solution takes place more rapidly if the pieces of silver are rolled in a coil; as a larger surface is thus exposed to the action of the acid. If the silver contain copper, it will form a solution of a greenish tint, not disappearing on the application of heat; and if a minute portion of gold be present, it will be left undissolved as a black powder. The acid should be pure also. The commercial nitric acid, as it frequently contains both muriatic and sulphuric acids, should never be used in this process. The muriatic acid gives rise to an insoluble chloride, and the sulphuric, to the sparingly soluble sulphate of silver. The proportion of acid employed by the London and Edinburgh Colleges is unnecessarily large; and hence it has been very properly reduced in the United States formula. As the salt sinks into a common crucible, the fusion should be performed in a porcelain one, the size of which should be sufficient to hold five or six times the quantity of the dry salt operated on, in order to prevent its overflowing in consequence of the ebullition. Sometimes small portions of the liquid are spirted out, against the occurrence of which the operator should be on his guard. When the mass flows like oil, as mentioned in the Edinburgh process, it is completely fused, and ready to be poured into the moulds. These should be warmed as well as greased, as otherwise the sticks will be very brittle. The object of the covering of paper is to protect them from the decomposing influence of light, and to prevent them from discolouring the fingers.

Properties. Nitrate of silver, as prepared by the above processes, is in the form of hard, brittle sticks, of a gray colour, and an austere, metallic taste. When broken across they exhibit a crystalline fracture, and their surface often becomes dark coloured, owing either to exposure to light, to fusion at too high a temperature, or to the presence of copper. This salt is soluble in its weight of cold water, and four times its weight of boiling alcohol. Its solution stains the skin of an indelible black colour. It is decomposed at a red heat, the acid being dissipated, and the oxide reduced. When pure it is not deliquescent, and when it possesses this quality, the presence of copper may be suspected. This metal may be detected by the use of ammonia, which will cause a blue tinge if it be present. It may be separated by solution and crystallization, the pure nitrate of silver crystallizing to the exclusion of the nitrate of copper, which remains in the mother water. Nitrate of silver is decomposed by common water, soaps, the fixed alkalies and their carbonates, lime-water, sulphuric, muriatic, and tartaric acids and their salts, solution of arsenite of potassa, hydrosulphuric acid gas and its compounds, and the astringent vegetable infusions. It is an anhydrous salt, consisting of one equiv. of nitric acid 54.15, and one of oxide of silver 116=170.15.

Medical Properties and Uses. Nitrate of silver, used internally, is tonic and antispasmodic. It was formerly employed in dropsy, but its hydragogue powers are doubted by modern practitioners. The principal diseases in which it has been tried are epilepsy, chorea, angina pectoris, and other spasmodic affections. In epilepsy it has gained some celebrity as a remedy; but, though sometimes beneficial, it often fails. Its effects have been found to be most favourable in this disease when it acts on the bowels. Whenever resorted to, caution must be exercised not to continue it too long, as it is apt to weaken the stomach. An incidental disadvantage from its use, is its occasional effect of giving the skin a dark hue, approaching to black, which is difficult to remove, but which is said to yield to a steady course of cream of tartar. Externally, this salt is employed as a stimulant and escharotic, either dissolved in distilled water, or in the solid state. In the proportion of about half a grain to the fluidounce of water, it has been recommended as a mouth wash, for healing ulcers produced by the use of mercurials. Dissolved to the extent of from one to five grains in the same quantity of water, it is used for the purpose of stimulating indolent ulcers, and as an injection for fistulous sores. A solution containing two grains to the fluidounce is an excellent application in ophthalmia with ulcers of the cornea, in fetid discharges from the ear, in aphthous affections of the mouth, and in spongy gums. It is in general most conveniently applied to ulcers by means of a camel's hair pencil. A drachm of the salt dissolved in a fluidounce of water, forms an escharotic solution, which may often be resorted to with advantage. But nitrate of silver is most frequently employed, as an escharotic, in the solid state; and as it is not deliquescent, nor apt to spread, it forms the most manageable caustic that can be used. It is employed to destroy strictures in the urethra, warts, fungous flesh and excrescences, incipient chancres, and the surface of other unhealthy ulcers. It forms a most efficacious application to certain ulcerations in the throat. Mr. Higginbottom insists upon its efficacy when freely applied to ulcers, so as to cover them with an eschar, as an excellent means of expediting their cicatrization. He alleges, that if an adheren eschar is formed, the parts underneath heal before it falls off.

The dose of nitrate of silver is an eighth of a grain, gradually increased to four or five grains, three times a day. It may be given in pill or solution; but the former mode is preferable, on account of its strong and disagreeable taste. The pill is usually made with crumb of bread, but as this contains common salt, which is incompatible, some absorbent vegetable powder, with mucilage of gum Arabic, is preferable. As the fused nitrate in the form of sticks, as prepared for the use of the surgeon, is apt to be impure, it would be a good rule to resort exclusively to the crystallized nitrate for internal exhibition. The Dublin College, adopting this sentiment, has made nitrate of silver officinal in the form of crystals. (See *Argenti Nitratis Crystalli*, Dub.)

Nitrate of silver, in an over-dose, produces the effects of the corrosive poisons. The proper antidote is a solution of common salt, which acts by converting the poison into the insoluble and therefore inert chloride of silver. Consecutive inflammation must be combated by bleeding, both general and local, and other antiphlogistic remedies. B.

ARGENTI NITRATIS CRYSTALLI. *Dub.* *Crystals of Nitrate of Silver.*

"Take of Silver, laminated and cut in pieces, *thirty-seven parts;* Diluted Nitric Acid *sixty parts.* Put the Silver in a glass vessel, and pour the Acid upon it. Dissolve the metal with a heat gradually increased, and by evaporation and refrigeration let crystals be formed. Dry them without heat, and preserve them in a glass bottle in a dark place." *Dub.*

The Dublin is the only Pharmacopœia noticed in this work which has made the crystals of nitrate of silver officinal; and the motive for doing so is to have a purer salt for internal exhibition than the fused nitrate generally is. In the formula, the error of the London and Edinburgh Colleges, of using an excess of acid, has been avoided. The crystals are in thin rhomboidal plates, often of large size. Their other properties, as well as their medical applications, are the same as those of the fused nitrate, to the article on which the reader is referred. B.

◆

ARSENICUM.

Preparations of Arsenic.

ARSENICUM ALBUM SUBLIMATUM. *Lond.* ARSENICI OXYDUM ALBUM SUBLIMATUM. *Dub.* *Sublimed White Arsenic.*

"Reduce White Arsenic to powder; then put it into a crucible, and, applying heat, sublime it into another crucible, inverted over the first." *Lond.*

"Reduce the Oxide of Arsenic to a coarse powder, and, avoiding the vapours, expose it to heat in a suitable vessel, that the White Oxide of Arsenic may sublime." *Dub.*

The London and Dublin Colleges, deeming the commercial white oxide of arsenic (*Acidum Arseniosum, U.S.*) not sufficiently pure for medicinal employment, have given the above formulæ for its purification. But as the commercial oxide itself has undergone a second sublimation, it would seem that these processes are superfluous. The only precaution necessary to be taken on the part of the apothecary, is to purchase the oxide in lump; for when in powder it is liable to be adulterated with chalk or sulphate of lime. The chemical, medical, and toxicological properties of this oxide, have been given under the head of *Acidum Arseniosum.*

Off. Prep. Liquor Arsenicalis, *Lond.*, *Dub.* B.

LIQUOR POTASSÆ ARSENITIS. *U.S.* LIQUOR ARSENICALIS. *Lond., Dub.* SOLUTIO ARSENICALIS. *Ed.* *Solution of Arsenite of Potassa. Fowler's Solution.*

"Take of Arsenious Acid, in very fine powder, Purest Carbonate of Potassa, each, *sixty-four grains;* Distilled Water *a sufficient quantity;* Compound Spirit of Lavender *four fluidrachms;* Boil the Arsenious Acid and Carbonate of Potassa with a pint of Distilled Water, till the Acid is entirely dissolved. To the solution, when cold, add the Spirit of Lavender, and afterwards sufficient Distilled Water to make it fill up exactly the measure of a pint." *U.S.*

The formula of the *London College* is the same as the above, with the exception that the "Sublimed White Arsenic" of this College is made use of instead of the commercial oxide, the "arsenious acid" of the United States Pharmacopœia. The *Dublin College* copies the London process, reducing the quantity of the arsenious acid and carbonate, from sixty-four to sixty grains. The *Edinburgh College* takes the same quantities of acid and carbonate as are directed in the United States and London formulæ, but adds half an ounce, instead of half a fluidounce, of the spirit of lavender, and uses sufficient water to make the whole solution weigh sixteen ounces.

This preparation originated with Dr. Fowler, and was intended as a substitute for the celebrated empyrical remedy known under the name of "the tasteless ague drop." It is an arsenite of potassa dissolved in water, and is formed by the combination of the arsenious acid with the potassa of the carbonate, the carbonic acid being expelled. The name, therefore, by which it is designated in the United States Pharmacopœia, is obviously the most correct. The spirit of lavender is added to give it taste, in order to prevent its being mistaken for simple water. The United States and London preparations are of the same strength. The Dublin is weaker, in consequence of the very injudicious alteration from the standard formula, of substituting sixty instead of sixty-four grains of arsenious acid to the pint of liquid. Dr. Barker, in his Observations on the Dublin Pharmacopœia, informs us, that the reason for this change was the supposition that less danger of error would arise in weighing sixty than sixty-four grains; as the former quantity could be weighed by a single weight. On this insufficient ground, the Dublin College have made their preparation to contain one-sixteenth of arsenious acid less than the corresponding preparation of the London College. The Edinburgh preparation is also weaker than the London and United States solutions, on account of the quantity of the menstruum being greater; sixteen ounces of the liquid, the quantity prepared by the Edinburgh College, measuring about six-sevenths of a fluidounce more than a pint.

To form a perfect arsenite of potassa, theory would call for 99.4 of acid to 138.54 of the carbonate, instead of equal parts; so that the quantity directed of the latter is deficient. In making this preparation, care should be taken that the arsenious acid be pure. Sulphate of lime is a common adulteration, and if present, will remain undissolved, and cause the solution to be weaker than it ought to be.

Properties. Solution of arsenite of potassa is a transparent liquid, having the colour, taste, and smell of the spirit of lavender. It is decomposed by the usual reagents of arsenic; such as nitrate of silver, the salts of copper, lime-water, hydrosulphuric acid gas, and hydrosulphates; and is incompatible with infusions and decoctions of cinchona. The salt which it contains is a diarsenite, consisting of one equiv. of arsenious acid 99.4 and two of potassa 94.3=193.7.

Medical Properties and Uses. This solution has the general action of the arsenical preparations on the animal economy, already described under the head of *Arsenious Acid.* Its liquid form makes it convenient for exhibition and gradual increase; and it is the preparation generally resorted to, when arsenic is given internally. It is employed principally in intermittent fever. Dr. Thomas D. Mitchell, Professor of Chemistry in the Medical College of Ohio, has given the result of his experience, as to its efficacy and safety in this disease, when exhibited in the large dose of fifteen or twenty drops three times a day. (*Med. Recorder*, iv. 640.) It is a valuable resource in the intermittents of children, who are with difficulty induced to swallow sufficient quantities of bark or even sulphate of quinia. Dr. Dewees (*Phil. Journ. of Med. and Phys. Sciences*, xiv. 187,) relates the case of a child only six weeks old, affected with a severe tertian, in which this solution was given with success. A fluidrachm was diluted with twelve fluidrachms of water; and of this six drops were given every four hours.

Fowler's solution, while partaking of the general therapeutical properties of the arsenical preparations, appears to be particularly adapted to the cure of several diseases. It has been employed with encouraging success in lepra and other inveterate cutaneous affections. Dr. S. Colhoun, (*Med. Recorder*, iii. 347,) relates five cases of nodes, successfully treated by it; and in consequence of his success, Dr. Baer of Baltimore, and Professor Eberle of Cincinnati, were induced to give the remedy a trial in this affection, and with satisfactory results. Several cases of chorea, cured by this remedy, are reported by Mr. Martin, Mr. Slater, and Dr. Gregory, in the Medico-Chirurgical Transactions of London. Two interesting cures of periodical headach, performed by this solution, are related by Dr. Otto of Philadelphia, in the fourth and fifth volumes of the N. A. Medical and Surgical Journal; the first occurring in the practice of Dr. Joseph M. Alexander of North Carolina, the second under his own observation.

Each fluidrachm of the solution contains half a grain of arsenious acid. The average dose for an adult is ten drops two or three times a day. For the peculiar effects which it produces in common with the other arsenical preparations, and for the signs by which the practitioner is warned that its further exhibition would be unsafe, the reader is referred to the article on *Arsenious Acid.*

B.

◆

BARYTA.

Preparations of Baryta.

BARYTÆ MURIAS. *U.S., Dub.* MURIAS BARYTÆ. *Ed.* *Muriate of Baryta.*

"Take of Carbonate of Baryta, in small fragments, *a pound;* Muriatic Acid *twelve fluidounces;* Water *three pints.* Mix the Acid with the Water, and gradually add the Carbonate of Baryta till effervescence ceases. Digest for an hour and filter; then evaporate the solution, and set it aside to crystallize. Repeat the evaporation and crystallization, so long as any crystals form." *U.S.*

"Take of Sulphate of Baryta *ten parts;* Wood Charcoal, in very fine powder, or Lampblack, *one part.* Roast the Sulphate of Baryta, and throw it while still red hot into water; then reduce it to a very fine powder in the manner directed for the preparation of chalk. Mix the powders intimately, put them into a crucible, and expose them to a red heat for four hours. Dissolve the mass when cold in Distilled Water, equal to ten times the weight of the Sulphate of Baryta, and filter the solution. Add to this, avoiding the vapours, as much Muriatic Acid as may be sufficient to saturate the Baryta. Then filter the liquor, and crystallize by evaporation and refrigeration." *Dub.*

By the above formulæ, it is seen that the muriate of baryta, in the U.S. process, is obtained from the native carbonate; in that of the Dublin College, from the native sulphate. The Edinburgh College gives separate formulæ for obtaining the salt in question from either of these native sources. The process in which the carbonate is used does not materially differ from that of the U.S. Pharmacopœia; and the formula for obtaining the muriate from the native sulphate is in principle the same as the corresponding process of the Dublin College, and, therefore, need not be quoted. When the carbonate is used, the process is a case of single elective affinity; the muriatic acid combining with the baryta, and the carbonic acid being expelled with effervescence. The process in which the sulphate of baryta is employed, is more complicated. The object of the roasting and quenching in water, is to render the sulphate more easily pulverizable. The calcination with carbonaceous matter deoxidizes its constituents, converting it into sulphuret of barium, the oxygen flying off in combination with the carbon, as carbonic oxide and acid. The sulphuret of barium, when dissolved in water, is converted, by union with the elements of water, into hydrosulphate of baryta; and this by the addition of muriatic acid is decomposed, hydrosulphuric acid gas being given off in large quantities, and muriate of baryta formed in solution, from which, in the usual manner, the solid salt is obtained.

Muriate of baryta may be obtained also from the sulphate, by calcining it either with muriate of lime, or carbonate of potassa. In the former case it is directly generated by double decomposition; in the latter, carbonate of baryta is in the first instance formed, which is easily converted into the muriate by solution in muriatic acid.

Of the officinal processes, that in which the native carbonate is used is the simplest and most convenient; but as it may happen that the operator possesses the native sulphate and not the carbonate, the additional process of the Edinburgh College may sometimes prove useful.

Properties. Muriate of baryta is a permanent white salt, possessing an acrid and disagreeable taste. It crystallizes in rectangular plates with beveled edges. It dissolves in about two and a half times its weight of cold, and in a less quantity of boiling water. It is scarcely soluble in absolute alcohol, but dissolves in spirit of wine. Alcohol, impregnated with it, burns with a yellow flame. When exposed to heat, it decrepitates, dries, and melts, and is converted into chloride of barium. It is decomposed by the sulphates, oxalates, and tartrates, and the alkaline phosphates, borates, and carbonates; also by the nitrate of silver, acetate and phosphate of mercury, and the acetate of lead. When pure, it does not deliquesce. If strontia be present, its alcoholic solution will burn with a red flame. Like all th soluble salts of baryta, it is poisonous. It consists of one equiv. of muriatic acid 36.42, one of baryta 76.7, and one of water 9=122.12; or, viewed as a chloride of barium, of one equiv. of chlorine 35.42, one equiv. o barium 68.7, and two equiv. of water 18. It is used in medicine only in solution.

Off. Prep. Liquor Barytæ Muriatis, *U.S.*, *Ed.*, *Dub.* B.

LIQUOR BARYTÆ MURIATIS. *U. S.* SOLUTIO MURIATIS BARYTÆ. *Ed.* BARYTÆ MURIATIS AQUA. *Dub.* *Solution of Muriate of Baryta.*

"Take of Muriate of Baryta *an ounce;* Distilled Water *three fluidounces.* Dissolve the Muriate of Baryta in the Water." *U.S.*

"Take of Muriate of Baryta *one part;* Distilled Water *three parts.* Dissolve." *Ed., Dub.* "The sp. gr. of this solution should be 1.230." *Dub.*

The muriate of baryta not being used in the solid state, this solution is intended for its convenient exhibition. The Edinburgh and Dublin formulæ agree in dissolving the salt in three times its weight of water. The U. S. preparation is somewhat stronger; inasmuch as three fluidounces weigh about a sixth of an ounce less than three ounces. The plan of the Dublin College is a good one, of designating the strength by the specific gravity. The solution should be limpid and colourless; and to make it so, the salt in crystals, and not in powder, should be employed. It is not saturated, which is an advantage; as otherwise it would be liable to grow weaker by a fall of temperature.

Medical Properties and Uses. This solution is deobstruent and anthelmintic, and in large doses poisonous. It was introduced into practice by Dr. Crawford as a remedy for cancer and scrofula. Its value in the latter disease has been particularly insisted on by Hufeland. This physician considers it to act more particularly on the lymphatic system, in the irritated states of which he esteems it a valuable remedy. Hence he recommends it in the scrofulous affections of delicate and irritable organs, such as the eyes, lungs, &c. In the commencement of scrofulous phthisis, he views it as one of the best remedies to which we can have recourse. It is employed also in diseases of the skin, in ulcers, and ophthalmia. The dose for an adult is about five drops, given twice or thrice a day, and gradually but cautiously increased, until it produces nausea, or some other sensible impression. When taken in an over-dose it causes violent vomiting and purging, vertigo, and other dangerous symptoms. To combat its poisonous effects, recourse must be had immediately to weak solutions of sulphate of magnesia or of soda, which act by converting the poison into the insoluble sulphate of baryta. If vomiting does not come on, it should be induced by tickling the fauces, or by the administration of an emetic.

B.

BISMUTHUM.

Bismuth.

BISMUTHI SUBNITRAS. *U.S., Lond., Dub.* *Subnitrate of Bismuth.* *White Oxide of Bismuth.*

"Take of Bismuth *an ounce;* Nitric Acid *a fluidounce and a half;* Distilled Water *a sufficient quantity.* Mix six fluidrachms of Distilled Wa-er with the Nitric Acid, and dissolve the Bismuth in the mixture; then filter he solution. To the filtered liquor add three pints of Distilled Water, and et the mixture by that the powder may subside. Lastly, having poured off he supernatant fluid, wash the Subnitrate of Bismuth with Distilled Water, vrap it up in bibulous paper, and dry it with a gentle heat." *U.S.*

The *London* formula, being the original of the above process, is not ma-erially different from it, and need not be quoted.

"Take of Bismuth, in powder, *seven parts;* Diluted Nitric Acid *twenty* *parts;* Distilled Water *one hundred parts.* Add the Bismuth gradually to the Acid, and dissolve by the assistance of heat. Mix the solution with the Water, and set the mixture by that the powder may subside. Wash this with distilled water, and dry it on bibulous paper with a gentle heat." *Dub.*

When bismuth is added to dilute nitric acid, red fumes are copiously given off; and the metal, oxidized by the decomposition of part of the nitric acid, is dissolved by the remainder, so as to form a solution of the nitrate of bismuth. This solution, after being filtered, is transparent and colourless, and has a caustic, very styptic taste; and, upon the addition of water, is decomposed into the subnitrate which precipitates, and a supernitrate which remains in solution. In order to obtain a smooth and light powder, which is most esteemed, it should be washed and dried as speedily as possible. In performing the process, it is more convenient to add the nitric solution to the water, as is done by the Dublin College, than to mix in the contrary order.

Properties. Subnitrate of bismuth is in the form of an insipid inodorous powder, of a pure white colour. It is slightly soluble in water, and readily so in the strong acids, from which it is precipitated by water. The fixed alkalies dissolve it sparingly, and ammonia more readily. It is darkened by hydrosulphuric acid gas and by exposure to light, and hence requires to be kept in well stopped bottles in a dark place. By the earlier chemists it was called *magistery of bismuth.* The perfumers, by whom it is sold as a paint for the complexion, denominate it *pearl white.* It consists of oxide of bismuth combined with a small portion of nitric acid, but with how much is not exactly known.

Medical Properties and Uses. This preparation is tonic and antispasmodic. It was originally introduced into practice by Dr. Odier of Geneva, and has been subsequently employed with advantage by several physicians both of this country and of Europe. It has been recommended in epilepsy, palpitation of the heart, and spasmodic diseases generally; but more particularly in various painful affections of the stomach, dependent on disordered digestion, such as cardialgia, pyrosis, and gastrodynia. Its use always blackens the stools, from the effect of the intestinal gases. The dose is one, gradually increased to twelve or fifteen grains, twice or thrice a day, and may be taken in pill, or mixed with powdered gum Arabic. In an over-dose it produces alarming gastric distress, nausea, vomiting, diarrhœa or constipation, colic, heat in the breast, slight rigors, vertigo, and drowsiness. The remedies are bland and mucilaginous drinks; and in case of inflammation, bleeding by leeches or venesection, enemata, and emollient fomentations. B.

CALX.

Preparations of Lime.

CALX E TESTIS. *Lond.* *Oyster-shell Lime.*

The *London College* prepares this in the manner directed for the preparation of lime from white marble, which is as follows. "Take of Whit Marble *a pound.* Break it into small fragments, and heat it in a crucible i a very strong fire for an hour, or until the carbonic acid is entirely expelled so that upon the addition of diluted acetic acid no effervescence may be produced."

When oyster-shells are exposed to a strong fire with the access of air, th animal matter is consumed, the carbonic acid driven off, and lime is left much purer than that obtained from limestone, but still containing a minute proportion of magnesian phosphate of lime and oxide of iron, which, according to Vauquelin, are associated in the shells with the carbonate of lime. The pharmaceutist may sometimes find advantage in resorting to this preparation in certain delicate chemical processes; but common lime is sufficiently pure for ordinary medicinal purposes. W.

LIQUOR CALCIS. *U.S., Lond.* Solutio Calcis, sive Aqua Calcis. *Ed.* Aqua Calcis. *Dub.* *Lime-water.*

"Take of Lime *four ounces* [half a pound, *Lond.*]; Distilled Water *a gallon* [twelve pints, *Lond.*] Pour the Water upon the Lime and stir them together; then immediately cover the vessel and set it aside for three hours. Keep the solution, together with the undissolved Lime, in stopped glass bottles, and pour off the clear liquor when it is wanted for use." *U.S., Lond.*

"Take of fresh burnt Lime *half a pound.* Sprinkle on it, in an earthen vessel, *four ounces* of Water, keeping the vessel covered while the lime grows hot and falls into powder; then pour on it *twelve pounds* of water, and mix the lime thoroughly with the water by agitation. After the lime has subsided, repeat the agitation, and do this about ten times, always keeping the vessel covered, that the free access of air may be prevented. Lastly, filter the water through paper, interposing glass rods between it and the funnel, that the solution may pass as quickly as possible. It should be kept in very closely stopped bottles." *Ed.*

"Take of fresh burnt Lime, boiling Water, each, *one part.* Put the Lime into an earthen vessel, and sprinkle the Water upon it, keeping the vessel closed while the Lime grows hot and falls into powder; then pour upon it *thirty parts* of cold water, and having again closed the vessel, shake the mixture frequently for twenty-four hours; lastly, after the lime has subsided pour off the clear solution, and keep it in closely stopped bottles." *Dub.*

A solution of lime in water is the result of these processes. The Edinburgh and Dublin Colleges first slake the lime, which is thus reduced to powder, and rendered more easily diffusible through the water employed to dissolve it. In other respects, the process of the U.S. and London Pharmacopœias is preferable. According to this, the solution is to be kept in bottles with a portion of undissolved lime, which causes it always to be saturated, whatever may be the temperature, and to whatever extent it may be exposed to the air. By taking care to have a considerable quantity of the solution in the bottle, and avoiding unnecessary agitation, the upper portion will always remain sufficiently clear for use. The employment of Distilled Water as the solvent may seem a useless refinement; and it certainly is unnecessary when pure spring or river water is attainable; but in many places the common water is very impure, and wholly unfit for a preparation, one of the most frequent uses of which is to allay irritability of stomach. Water dissolves but a minute proportion of lime, and contrary to the general law, less when hot than cold. The employment of boiling water, directed in the original edition of the U.S. Pharmacopœia, is, therefore, improper, or at least unnecessary. According to Mr. Phillips, a pint of water at 212° dissolves 5.6 grains of lime, at 60°, 9.7 grains, and at 32°, 11.0 grains. When a cold saturated solution is heated, a deposition of lime takes place.

Properties. Lime-water is colourless, inodorous, and of a disagreeable alkaline taste, changes vegetable blues to green, and forms an imperfect soap with oils. Exposed to the air it attracts carbonic acid, and becomes covered with a pellicle of insoluble carbonate of lime, which, subsiding after a time, is replaced by another, and so on successively till the whole of the lime is exhausted. Hence the necessity of keeping lime-water either in closely corked bottles which should be full, or, what is more convenient, in bottles with an excess of lime.

Medical Properties and Uses. Lime-water is antacid, tonic, and astringent, and is very usefully employed in dyspepsia with acidity of stomach, diarrhœa, diabetes, and gravel attended with superabundant secretion of uric acid. Mixed with an equal measure of milk, which completely covers its offensive taste, it is one of the best remedies in our possession for nausea and vomiting dependent on irritability of stomach. We have found a diet exclusively of lime-water and milk to be more effectual than any other plan of treatment in dyspepsia accompanied with vomiting of food. In this case one part of the solution to two or three parts of milk is usually sufficient. Lime-water is also thought to be useful by dissolving the intestinal mucus in cases of worms and other complaints connected with an excess of this secretion. Externally it is employed as a wash in tinea capitis and scabies, as an application to foul and gangrenous ulcers, as an injection in leucorrhœa and ulceration of the bladder or urethra, and, mixed with linseed or olive oil, as a liniment in burns and scalds.

The dose is from two to four fluidounces taken several times a day. When employed to allay nausea, it is usually given in the dose of a tablespoonful mixed with the same quantity of new milk, and repeated every twenty or thirty minutes. If too long continued it debilitates the stomach.

Off. Prep. Aqua Calcis Composita, *Dub.*; Infusum Sarsaparillæ Compositum, *Dub.*; Linimentum Calcis, *U.S.*, *Ed.*, *Dub.* W.

AQUA CALCIS COMPOSITA. *Dub.* *Compound Lime-water.*

"Take of Guaiacum Wood, rasped, *half a pound;* Liquorice Root, sliced and bruised, *an ounce;* Sassafras Bark, bruised, *half an ounce;* Coriander Seeds *three drachms;* Lime-water *six pints.* Macerate without heat, for two days, in a close bottle, occasionally shaking, and filter." *Dub.*

This is a very inert preparation, and should be ranked among the infusions, as the lime-water can scarcely fail to be decomposed during the process. W.

CALCIS CARBONAS PRÆCIPITATUM. *Dub.* *Precipitated Carbonate of Lime.*

"Take of Water of Muriate of Lime *five parts.* Add *three parts* of Carbonate of Soda, dissolved in four times its weight of Distilled Water. Wash the precipitate three times with a sufficient quantity of water; then collect it and dry it on a chalk-stone, or on bibulous paper." *Dub.*

In this process a mutual interchange of principles takes place, resulting in the production of the muriate of soda which remains in solution, and the carbonate of lime which precipitates. Of the crystallized carbonate of soda, 143.42 parts decompose 55.92 of the chloride of calcium. The Dublin Water of Muriate of Lime contains two parts in nine of chloride of calcium. From these data it may be deduced, that the carbonate of soda in this formula is in very slight excess. The Precipitated Carbonate of Lime is very pure and finely divided, but probably has no such superiority over prepared chalk as to counterbalance its greater expensiveness.

Off. Prep. Hydrargyrum cum Cretâ, *Dub.* W.

CALCIS CARBONAS PRÆPARATUS. *U.S.* CRETA PRÆPARATA. *Lond., Dub.* CARBONAS CALCIS PRÆPARATUS. *Ed.* *Prepared Carbonate of Lime. Prepared Chalk.*

"Take of Carbonate of Lime [Chalk, *Lond.*] *a pound.* Add a little Water to the Carbonate of Lime [Chalk, *Lond.*], and rub it into a fine powder. Throw this into a large vessel full of water; then stir it, and, after a short interval, pour the supernatant liquor, while yet turbid, into another vessel, and set it by that the powder may subside; lastly, having poured off the water, dry the powder." *U.S., Lond.*

"Carbonate of Lime, after having been rubbed to powder in an iron mortar, and levigated with a little water on a porphyry stone, is to be put into a large vessel, and water to be poured upon it, which, after the vessel has been frequently shaken, is to be poured off loaded with the fine powder. The subtile powder, which subsides when the water is allowed to rest, is to be dried. The coarse powder, which the water could not suspend, may be again levigated, and treated in the same manner." *Ed.*

"Take of Chalk *any quantity.* Rub it to powder in an earthenware mortar, with the addition of a little water; then mix it with a sufficiently large quantity of water by agitation, and after a short interval, when the coarser particles have subsided, pour off the liquor. This may be several times repeated, each time after trituration. Finally, collect the very fine powder, which after some time will subside, and dry it upon an absorbent stone or paper." *Dub.*

The object of these processes is to reduce chalk to very fine powder. The mineral, previously pulverized, is rubbed with a little water upon a porphyry slab by means of a rubber of the same material, and having been thus very minutely divided, is agitated with water, which upon standing a short time deposites the coarser particles, and being then poured off, slowly lets fall the remainder in an impalpable state. The former part of the process is called *levigation*, the latter *elutriation.* The soft mass which remains after the decanting of the clear liquor, is made to fall upon an absorbent surface in small portions, which when dried have a conical shape.

Medical Properties and Uses. This is the only form in which chalk is used in medicine. It is an excellent antacid; and as the salts which it forms in the stomach and bowels are not purgative, it is admirably adapted to diarrhœa accompanied with acidity. It is frequently employed as an application to burns and ulcers, the ichorous discharge from which it absorbs, and thus prevents from irritating the diseased surface or the sound skin. It probably also does good, in these cases, by a peculiar action upon the part to which it is applied. It is given internally in the form of powder, or suspended in water by the intervention of gum Arabic and sugar. (See *Mistura Calcis Carbonatis.*) The dose is from ten to forty grains or more.

Off. Prep. Confectio Aromatica, *Dub.;* Hydrargyrum cum Calcis Carbonate, *U.S. Lond., Dub.;* Mistura Calcis Carbonatis, *U.S., Lond., Ed., Dub.;* Pulvis Cretæ Compositus, *Lond., Ed., Dub.;* Pulvis Opiatus, *Ed.;* Trochisci Calcis Carbonatis, *U.S., Ed.*

W.

TESTA PRÆPARATA. *U.S.* TESTÆ PRÆPARATÆ. *Lond.* *Prepared Oyster-shell.*

"Take of Oyster-shell *any quantity.* Free it from extraneous matter, and wash it with boiling water; then prepare it in the manner directed for Carbonate of Lime." *U.S., Lond.*

Prepared oyster-shell differs from prepared chalk in containing animal matter, which being very intimately blended with the carbonate of lime, is supposed by some physicians to render the preparation more acceptable to a delicate stomach. It is given as an antacid in diarrhœa, in the dose of from ten to thirty grains frequently repeated.

Off. Prep. Confectio Aromatica, *Lond.* W.

LIQUOR CALCIS MURIATIS. *U.S., Lond.* SOLUTIO MURIATIS CALCIS. *Ed.* CALCIS MURIATIS AQUA. *Dub.* *Solution of Muriate of Lime.*

"Take of Hard Carbonate of Lime [White Marble], broken into pieces, *nine ounces;* Muriatic Acid *sixteen ounces;* Distilled Water *a sufficient quantity.* Mix the Acid with half a pint of the Distilled Water, and gradually add the Carbonate of Lime. When the effervescence shall have ceased, digest for an hour; then pour off the liquor, and evaporate to dryness. Dissolve the residuum in its own weight and a half of the Distilled Water, and filter the solution." *U.S.*

The *London College* dissolves *two ounces* of muriate of lime (chloride of calcium) in *three fluidounces* of distilled water, and filters through paper. The *Edinburgh* process is essentially the same as that of the U.S. Pharmacopœia; which was copied from it with slight variations to adapt it to the plan of the work. The *Dublin College* dissolves two parts of muriate of lime (chloride of calcium) in seven parts of distilled water, and states the sp. gr. of the solution at 1.202.

By the U.S. and Edinburgh processes a chloride of calcium is first formed, and then, as in the processes of the London and Dublin Colleges, dissolved in a certain proportion of water. As the chloride by its union with the elements of water, is converted into muriate of lime, the solution properly takes the name by which it is designated above. The U.S., London, and Edinburgh preparations agree very nearly in strength, containing 1 part of the chloride in 2.5 parts of the solution. The Dublin contains only 1 part in 4.5, and is therefore little more than half as strong as the others.

The solution of muriate of lime has a disagreeable, bitter, acrid taste. It is decomposed by sulphuric acid and the soluble sulphates; by potassa, soda, and their carbonates; by carbonate of ammonia, tartrate of potassa and soda, nitrate of silver, nitrate and acetate of mercury, and acetate of lead. The mode of preparing chloride of calcium and its chemical properties, are detailed under the head of *Calcii Chloridum* in the Materia Medica.

Medical Properties and Uses. The muriate of lime is considered tonic and deobstruent. It was first brought into notice as a remedy by Fourcroy, and was at one time much used in scrofulous diseases and goitre. It still continues to be a favourite with some physicians, but is less employed than formerly. When too largely taken it sometimes produces nausea, but is a much safer remedy than the muriate of baryta which has been recommended in the same complaints. The dose of the solution is from thirty minims or drops to a fluidrachm, to be repeated twice or three times a day, and gradually increased to two, three, or even four fluidrachms. It may be given in milk or sweetened water.

Off. Prep. Calcis Carbonas Præcipitatum. *Dub.* W.

CALCIS PHOSPHAS PRÆCIPITATUM. *Dub.* *Precipitated Phosphate of Lime.*

"Take of Burnt Bones, in powder, *one part;* Diluted Muriatic Acid, Water, each, *two parts.* Digest together for twelve hours, and filter the solution. Add as much Water of Caustic Ammonia as will be sufficient to precipitate the Phosphate of Lime. Wash this with a large proportion of water, and finally dry it." *Dub.*

The muriatic acid dissolves the phosphate of lime of the bones, and lets it fall on the addition of ammonia, in a state of minute division. The ablution is intended to free it from any adhering muriate of ammonia. Thus obtained, phosphate of lime is in the form of a white powder, without taste or smell, insoluble in water, but very soluble in nitric, muriatic, and acetic acids, from which it is precipitated unchanged on the addition of ammonia.

If this preparation possesses any advantage over burnt hartshorn, it is in the state of minute division to which it has been brought by precipitation. It may be given in the same complaints and in the same dose; but is probably quite inert. (See *Cornu Ustum.*) W.

CORNU USTUM. *Lond.* PULVIS CORNU CERVINI USTI. *Dub.* *Burnt Hartshorn.*

"Burn pieces of Hartshorn in an open fire until they are thoroughly white; then powder them, and prepare them in the manner directed for Chalk." *Lond.*

The *Dublin College* gives similar directions.

The horn must not only be heated, but also burnt, in order that the animal matter may be entirely consumed. The operation may be performed in a common furnace or stove, the air being freely admitted. Care should be taken that the heat be not too violent, as otherwise the external surface of the horn may become vitrified, and prevent the complete combustion of the interior portion, while it is itself rendered less fit for use. Burnt hartshorn consists of phosphate of lime, with a minute proportion of lime, derived from the carbonate contained in the horns. It may be inferred, from the analysis of hartshorn by M. Guillot, that the proportion of free lime in this preparation is less than one per cent. (See *Cornu Cervi Elaphi.*)

Medical Properties and Uses. The opinion formerly entertained, that burnt hartshorn was antacid, has been abandoned since the discovery of its chemical nature. Its composition suggested its application to the cure of rachitis and mollities ossium, of which the prominent character is a deficiency of phosphate of lime in the bones; and it is said to have been employed in some cases, in connexion with phosphate of soda, with apparent success. Experience, however, has not confirmed the first report in its favour. It is probably altogether inert. The dose is twenty grains or more.

* * *

CATAPLASMATA.

Cataplasms.

Cataplasms or poultices are moist substances intended for external application, of such a consistence as to accommodate themselves accurately to the surface to which they are applied, without being so liquid as to spread over the neighbouring parts, or so tenacious as to adhere firmly to the skin. As they are in this country scarcely ever prepared by the apothecary, they were not deemed by the compilers of the United States Pharmacopœia proper objects for officinal direction. W.

CATAPLASMA ALUMINIS. *Dub.* *Alum Cataplasm.*

"Take the Whites of *two* Eggs; of Alum *a drachm.* Shake them together so as to make a coagulum." *Dub.*

A common mode of preparing the alum poultice, is to rub the whites of eggs briskly in a saucer with a lump of alum till the liquid coagulates. The curd produced by coagulating milk with alum is sometimes used as a substitute.

The alum cataplasm is an astringent application, occasionally employed in incipient, purulent, or chronic ophthalmia. It is placed over the eye enclosed between folds of cambric or soft linen. It is also esteemed useful in chilblains when the skin is not broken. W.

CATAPLASMA CARBONIS LIGNI. *Dub.* *Charcoal Cataplasm.*

"Take a sufficient quantity of Wood Charcoal red hot from the fire, and having extinguished it by sprinkling dry sand over it, reduce it to very fine powder, and incorporate it with the Simple Cataplasm in a tepid state." *Dub.*

Charcoal, recently prepared, has the property of absorbing and neutralizing those principles upon which the offensive odour of putrefying animal substances depends. In the form of poultice it is an excellent application to foul and gangrenous ulcers, correcting their fetor, and improving the condition of the sore. It should be frequently renewed. W.

CATAPLASMA CONII. *Dub.* *Hemlock Cataplasm.*

"Take of Dried Hemlock Leaves *an ounce;* Water *a pint and a half.* Boil down to a pint, and having strained the liquor, add as much of the powdered leaves as may be sufficient to form a cataplasm." *Dub.*

This cataplasm may be advantageously employed as an anodyne application to cancerous, scrofulous, syphilitic, and other painful ulcers: but its liability to produce narcotic effects by the absorption of the active principle of the hemlock, should not be overlooked. W.

CATAPLASMA DAUCI. *Dub.* *Carrot Cataplasm.*

"Take of the Root of the cultivated Carrot *any quantity.* Boil the root in water until it becomes sufficiently soft to form a cataplasm." *Dub.*

Emollient poultices may be prepared from any of the tender culinary roots, from turnips and potatoes as well as carrots, by boiling them, removing the external skin, and mashing them into a soft pulp, which may be rendered uniform by pressing it through a coarse sieve or cullender. But these poultices possess no specific power, and act on the same principles with those made with bread and milk, and flaxseed meal.

The carrot cataplasm, when designed to produce a peculiar impression, should be made by grating the fresh roots into a pulp. In this state it possesses a slightly stimulant property, which renders it useful in weak, flabby, ill-conditioned, and offensive ulcers. By boiling, this property is diminished, if not lost; and the carrot becomes a mild and nutritive article of food. W.

CATAPLASMA FERMENTI. *Lond.* CATAPLASMA FERMENTI CEREVISIÆ. *Dub.* *Yeast Cataplasm.*

"Take of Flour [wheat flour] *a pound;* Yeast *half a pint* [half a pound, *Dub.*] Mix and expose the mixture to a gentle heat until it begins to rise." *Lond.*, *Dub.*

By exposing a mixture of yeast and flour to a gentle heat, fermentation takes place, and carbonic acid gas is extricated, which causes the mixture to swell, and is the source of its peculiar virtues. The yeast cataplasm is gently stimulant, and is sometimes applied with much benefit to foul and gangrenous ulcers, the fetor of which it corrects, while it is supposed to hasten the separatiou of the slough. W.

CATAPLASMA SIMPLEX. *Dub.* *Simple Cataplasm.*

"Take of the powder for a Cataplasm *any quantity;* Boiling Water sufficient to form a tepid cataplasm, the surface of which should be covered with olive oil." *Dub.*

The Dublin "Powder for a Cataplasm," consists of one part of flaxseed meal remaining after the expression of the oil, and two parts of oat meal. The flaxseed meal which has not been submitted to pressure is decidedly preferable, and answers an excellent purpose when mixed with boiling water, without other addition. Fresh lard or olive oil spread upon the surface of the poultice serves to prevent its adhesion to the skin, and to preserve its softness.

The use of this and other emollient cataplasms is to relieve the tense condition of the vessels in inflammation, and to promote suppuration. They act simply by their warmth and moisture. The one most extensively employed, perhaps because its materials are always at hand, is that prepared by heating together milk and the crumb of bread. The milk should be quite sweet, and fresh lard should be incorporated with the poultice. Mush made with the meal of Indian corn also forms an excellent emollient cataplasm. W.

CATAPLASMA SINAPIS. *Lond., Dub.* *Mustard Cataplasm.*

"Take of Mustard Seed, Linseed [flaxseed], each, in powder, *half a pound;* Hot Vinegar *a sufficient quantity.* Mix, until they acquire the consistence of a cataplasm." *Lond.*

The *Dublin College* orders the same seeds in the same proportion, and states that the cataplasm may be made more stimulating by the addition of two ounces of scraped horse-radish.

The simplest and most effectual mode of preparing a mustard poultice, is to mix the powdered mustard of the shops with a sufficient quantity of warm water to give it a due consistence. When a weaker preparation is required, an equal portion or more of rye or wheat flour should be added. Vinegar never increases its efficiency, and in the case of the black mustard seed, has been ascertained by MM. Troupeau and Blanc to diminish its rubefacient power. (See *Sinapis.*)

These poultices are frequently called *sinapisms.* They are powerfully rubefacient, exciting a sense of warmth in a few minutes, and usually becoming insupportably painful in less than an hour. When removed, they leave the surface intensely red and burning; and the inflammation frequently terminates in desquamation, or even blistering, if the application has been too long continued. Obstinate ulcers and gangrene also sometimes result from the protracted action of mustard, especially on parts possessed of little vitality. As a general rule, the poultice should be removed when the patient complains much of the pain; and in cases of insensibility should not, unless greatly diluted, be allowed to remain longer than one, or at most two hours; as violent inflammation, followed by obstinate ulceration, is apt to occur upon the establishment of reaction in the system. In children also particular care is necessary to avoid this result. The poultice should be thickly spread on linen, and may be covered with gauze or unsized paper in order to prevent its adhesion to the skin. If hairs are present they should be removed by the razor. Sinapisms may be employed in all cases in which it is desirable to produce a very speedy and powerful rubefacient impression. W.

CERATA.

Cerates.

These are unctuous substances consisting of oil or lard, united with wax, spermaceti, or resin, to which various medicaments are frequently added. Their consistence, which is intermediate between that of ointments and of plasters, is such that they may be spread at ordinary temperatures upon linen or leather, by means of a spatula, and do not melt or run when applied to the skin. In preparing them, care should usually be taken to select the oil or lard perfectly free from rancidity. W.

CERATUM ARSENICI. *U.S.* *Cerate of Arsenic.*

"Take of Arsenious Acid, in very fine powder, *a scruple;* Simple Cerate *an ounce.* Mix the Acid with the Cerate, previously softened by heat."

This is sometimes employed as a dressing to cancerous ulcers. Its effects should be carefully watched; and if constitutional symptoms appear, its use should be suspended. W.

CERATUM CANTHARIDIS. *U.S.* EMPLASTRUM CANTHARIDIS. *Lond., Dub.* EMPLASTRUM CANTHARIDIS VESICATORIÆ. *Ed.* *Cerate of Spanish Flies.* EMPLASTRUM EPISPASTICUM. *Blistering Plaster.*

"Take of Spanish Flies, in powder, *a pound*; Yellow Wax, Resin, Olive Oil, each, *eight ounces.* To the Wax, Resin, and Oil, previously melted together, add the Spanish Flies, and stir the mixture constantly until cool." *U.S.*

The *London College* orders a pound of Spanish flies, a pound and a half of wax plaster, and half a pound of lard; the *Edinburgh*, equal weights of flies, suet, yellow wax, and white resin; and the *Dublin*, a pound of flies, a pound of yellow wax, four ounces of yellow resin, half a pound of suet, and half a pound of lard.

This is the common *blistering plaster* of the shops. As it can be readily spread without the aid of heat, it is properly a cerate, and is therefore correctly named in the U.S. Pharmacopœia. Though essentially the same in character as prepared by the different processes, it varies somewhat in strength. The U.S. and London preparations have the same proportion of flies, but are stronger than those of the Edinburgh and Dublin Colleges. One of the two former therefore is preferable, and our own has this advanvantage, that it does not require the previous preparation of the wax plaster. Care is requisite in making the cerate not to injure the flies by heat. They should not, therefore, be added to the other ingredients until immediately before these begin to stiffen after having been removed from the fire. It is desirable also that the flies should be very finely powdered.

The cerate is the most convenient form in which cantharides can be applied for the purpose of raising a blister, and it is always effectual in ordinary conditions of the system, if the flies are good and not injured in the preparation. It should be spread on soft leather, though linen or even paper will answer the purpose when this is not to be had. An elegant mode of preparing it for use, is to spread a piece of leather of a proper size first with adhesive plaster, and afterwards with the cerate, leaving a margin of the former uncovered, in order that it may adhere to the skin. Heat is not requisite, and should not be employed in spreading the cerate. It is customary with some to sprinkle powdered flies upon the surface of the plaster, press them lightly with a roller, and then shake off the portion which has not adhered; but if the flies originally employed were good, this addition is superfluous.

Upon the application of the plaster, the skin should be moistened with warm vinegar or other liquid; and a good rule is to cover the surface of the plaster closely with very thin gauze or unsized paper, which prevents any of the cerate from adhering to the cuticle. In the cases of adults, when the full operation of the flies is desirable, and the object is to produce a permanent effect, the application should be continued for twelve hours, and upon the scalp for twenty-four hours. In very delicate persons, however, or those subject to strangury, or upon parts of a loose texture, or when the object is merely to produce a blister to be healed as speedily as possible, the plaster should remain no longer than is necessary for the production of full redness of the skin, which generally occurs in five or six hours, or even in a shorter time. It should then be removed, and followed by a bread and milk poultice, or some other emollient dressing, under which the cuticle rises, and a full blister is usually produced.* By this management the patient will generally escape strangury, and the blister will very quickly heal after the discharge of the serum. In young children, cantharides sometimes produce alarming and even fatal ulceration, if too long applied. From two to four hours are usually sufficient to answer any desirable purpose. When the head, or other very hairy part is to be blistered, an interval of ten or twelve hours should, if possible, be allowed between the shaving of the part and the application of the plaster; so that the abrasions of the cuticle may heal, and some obstacle be offered to the absorption of the active principle of the flies. After the blister has been formed, it should be opened at the most depending parts, and, the cuticle being allowed to remain, should be dressed with simple cerate; but if it be desirable to maintain the discharge for a short time, resin cerate should be used, and the cuticle removed, if it can be done without inconvenience. The effects of an issue may be obtained by employing savine ointment, or the ointment of Spanish flies, as a dressing. If much inflammation should take place in the blistered surface, it may be relieved by emollient poultices, or weak lead water. Where there is an obstinate indisposition to heal, we have found nothing so effectual as the cerate of subacetate of lead, combined with an equal weight of simple cerate. When deep and extensive ulceration occurs in consequence of general debility, Peruvian bark or sulphate of quinia should be used with nutritious aliment.

A solution of cantharidin in olive oil, applied to the skin by means of a piece of paper saturated with it, has been proposed by the French pharmaceutists as a substitute for the ordinary blistering plaster; but if pure cantharidin is used, the preparation would be too expensive. A decoction of the flies in olive oil or oil of turpentine, would answer the same purpose; but is not likely to supersede the cerate.

It is said that by ebullition in water, the flies are deprived of their property of producing strangury, while their vesicating powers remain unaltered. (*Paris's Pharmacologia.*) Dr. Theophilus Beasly of Philadelphia, has been in the habit of employing a cerate made with cantharides prepared in this manner, and has never known it to produce strangury in more than two or three instances. He boils the *unpowdered flies* for fifteen minutes, esteeming a shorter time insufficient to deprive them of this property, while if the boiling be continued much longer, their blistering power is impaired. (*Journ. of the Phil. Col. of Pharm.* iv. 185.) In a letter addressed to one of the authors by Dr. James Couper of Newcastle, Delaware, a similar method of preparing the flies is recommended as an expedient against strangury, both from his own experience and that of the late Dr. Groom of Elkton, Maryland, from whom he derived his knowledge of the plan. Dr. Groom's method was to pour upon the flies in their perfect state sufficient boiling water completely to cover them, to stir them for about five minutes, then to pour off the liquor and dry them upon blotting paper, in the sun, or by the heat of a stove-room. W.

---

* Dr. M. B. Smith of Philadelphia has informed us that he has frequently employed uva ursi as a preventive of strangury from blisters, and has never found it to fail. He gives a small wineglassful of the officinal decoction, (see *Decoctum Uvæ Ursi,*) every hour, commencing two hours after the application of the blister.

CERATUM CETACEI. *U.S., Lond.* CERATUM SIMPLEX. *Ed.* UNGUENTUM CETACEI. *Dub.* *Spermaceti Cerate.*

"Take of Spermaceti *an ounce;* White Wax *three ounces;* Olive Oil *six fluidounces.* Melt together the Spermaceti and Wax; then add the Oil previously heated, and stir the mixture until cool." *U.S.*

The *London College* directs half an ounce of Spermaceti, two ounces of white wax, and four fluidounces of olive oil; the *Edinburgh*, six parts of olive oil, three parts of white wax, and one part of spermaceti; the *Dublin*, half a pound of white wax, a pound of spermaceti, and three pounds of lard.

The direction to heat the oil before adding it to the other ingredients is peculiar to our Pharmacopœia. If added cold, it is apt to produce an irregular congelation of the wax and spermaceti, and thus to render the preparation lumpy. This cerate is employed as a dressing for blisters, excoriated surfaces, and wounds; and as the basis of more active preparations. When the ingredients are pure and sweet, it is perfectly free from irritating properties.

Off. Prep. Ceratum Cantharidis, *Lond.;* Ceratum Carbonatis Zinci Impuri, *Ed.* W.

CERATUM PLUMBI CARBONATIS. *U.S.* *Cerate of Carbonate of Lead.*

"Take of Plaster of Carbonate of Lead *ten ounces;* Olive Oil *two fluidounces.* Add the Oil to the Plaster previously melted, and stir them constantly until cool." *U.S.*

This is useful as a desiccative and sedative application to excoriated and irritated surfaces. W.

CERATUM PLUMBI SUBACETATIS. *U.S.* CERATUM PLUMBI COMPOSITUM. *Lond.* *Cerate of Subacetate of Lead. Goulard's Cerate.*

"Take of Solution of Subacetate of Lead *two fluidounces and a half;* Yellow Wax *four ounces;* Olive Oil *nine fluidounces;* Camphor *half a drachm.* Mix the Wax, previously melted, with eight fluidounces of the Oil; then remove the mixture from the fire, and when it begins to thicken, gradually pour in the Solution of Subacetate of Lead, stirring constantly with a wooden spatula till it becomes cool. Lastly, add the Camphor dissolved in the remainder of the Oil and mix." *U.S., Lond.*

This preparation received the name by which it is commonly known, from M. Goulard, by whom it was employed and recommended. It is used to dry up excoriations, to relieve the inflammation of burns, scalds, and chilblains, and to remove cutaneous eruptions. We have found it more effectual than any other application to blistered surfaces indisposed to heal; and, on the recommendation of Dr. Parrish, have used it in the following combination with advantage in various cutaneous eruptions of a local character. Take of cerate of subacetate of lead, simple cerate, each, *half an ounce;* calomel, powdered opium, each, *a drachm;* mix them. The same preparation, without the opium, was a favourite remedy with the late Dr. Wistar in similar complaints.

W.

CERATUM RESINÆ. *U.S., Lond.* UNGUENTUM RESINOSUM. *Ed.* UNGUENTUM RESINÆ ALBÆ. *Dub.* *Resin Cerate.*

"Take of Resin *five ounces;* Lard *eight ounces;* Yellow Wax *two ounces.* Melt them together, and stir them constantly until cool." *U.S.*

The proportions directed by the *Edinburgh College* are the same as the above. The *London College* orders of yellow resin and yellow wax, each, a pound, and of olive oil a pint. The resin and wax are melted together over a slow fire, the oil then added, and the mixture while hot strained through linen. By the *Dublin* process, four pounds of lard, two pounds of white resin, and one pound of yellow wax are made into an ointment, and strained while hot through a sieve.

As resin often contains impurities, the cerate should be strained before it cools.

Resin cerate, commonly called *basilicon ointment*, is much used as a gently stimulant application to blistered surfaces, indolent ulcers, burns, scalds, and chilblains. We have found no application more effectual in disposing the ulcers which follow burns to heal.

Off. Prep. Ceratum Sabinæ, *U.S.;* Linimentum Terebinthinæ, *U.S., Lond., Dub.;* Unguentum Cantharidis, *U.S., Lond., Ed., Dub.;* Unguentum Cupri Subacetatis, *Dub., Ed.*

W.

CERATUM RESINÆ COMPOSITUM. *U.S.* *Compound Resin Cerate.*

"Take of Resin, Suet, Yellow Wax, each, *a pound;* Turpentine *half a pound;* Flaxseed Oil *half a pint.* Melt them together, and stir them constantly until cool." *U.S.*

This should be strained through linen before cooling, in order to separate the impurities. It is somewhat more stimulating than the preceding, but is applicable to similar purposes, particularly to the treatment of indolent ulcers. Under the name of *Deshler's salve,* it is popularly employed in some parts of the United States.

W.

CERATUM SABINÆ. *U.S., Lond.* CERATUM JUNIPERI SABINÆ. *Ed.* UNGUENTUM SABINÆ. *Dub.* *Savine Cerate.*

"Take of Savine, in powder, *two ounces;* Resin Cerate *a pound.* Mix the Savine with the Cerate previously softened." *U.S.*

The *London College* orders one pound of fresh savine leaves, bruised, to be boiled with half a pound of yellow wax and two pounds of lard previously melted together, and the whole to be strained through linen. The *Edinburgh* process is essentially the same. The *Dublin College* employs only half a pound of the leaves, which it directs to be boiled in the lard till they become crisp; the lard is then to be strained with expression, the wax added, and the whole melted together.

As the savine used in this country is generally brought from Europe in the dried state, we are compelled to resort to the mode of preparing the cerate directed in the U.S. Pharmacopœia. Nor have we found the preparation thus made to be "intolerably acrid and almost caustic," as Dr. Duncan describes it. On the contrary, it answers very well the purpose for which it is used—that of maintaining the discharge from blistered surfaces. A cerate prepared in the same manner from the leaves of the red cedar (*Juniperus Virginiana*) is sometimes substituted for that of savine, but is less efficient. It was originally introduced into the U.S. Pharmacopœia, but has been omitted in the last edition.

Prepared according to the processes of the British Colleges, savine cerate has a fine deep green colour, and the odour of the leaves. It should be kept in closely covered vessels, as its virtues are impaired by exposure.

Savine cerate is preferable to the ointment of Spanish flies as a dressing for perpetual blisters, from the circumstance that it has no tendency to produce strangury. The white coating which forms during its use upon the blistered surface should be occasionally removed, as it prevents the contact of the cerate. W.

CERATUM SAPONIS. *U.S., Lond.* *Soap Cerate.*

"Take of Soap *eight ounces;* Yellow Wax *ten ounces;* Semivitrified Oxide of Lead, in powder, *a pound;* Olive Oil *a pint;* Vinegar *a gallon.* Boil the Vinegar with the Oxide of Lead over a slow fire, constantly stirring, till the union is complete; then add the Soap, and again boil in a similar manner, until all the moisture is dissipated; lastly, with these ingredients mix the Wax previously melted with the Oil." *U.S., Lond.*

In this process, the subacetate of Lead formed by the action of the vinegar upon the litharge, is decomposed by the soap, the soda of which unites with the acetic acid, and the oil with the oxide of lead in the same manner as in the formation of the Emplastrum Plumbi. The wax and oil subsequently added merely serve to give due consistence to the preparation. Soap cerate is thought to be cooling and sedative; and is sometimes used in scrofulous swellings and other instances of chronic external inflammations. It was formerly employed by Mr. Pott as a dressing for fractured limbs; but answers no other purpose in these cases than to yield mechanical support. W.

CERATUM SIMPLEX. *U.S., Lond.* *Simple Cerate.*

"Take of Lard *eight ounces;* White Wax *four ounces.* Melt them together, and stir them constantly until cool." *U.S.*

The *London College* directs that four fluidounces of olive oil be mixed with four ounces of yellow wax previously melted.

We prefer the formula of the U.S. Pharmacopœia. Lard is preferable to olive oil, as it may always be had perfectly sweet, and is the mildest application which can be made to irritated surfaces. In the preparation of this cerate, peculiar care should be observed that the oleaginous ingredient be entirely free from rancidity, and that the heat employed be not sufficient to produce the slightest decomposition; for the value of the preparation depends on its perfect blandness. It is used for dressing blisters, wounds, &c., in all cases in which the object is to exclude the external air and preserve the moisture of the part, and at the same time to avoid all irritation. It is sometimes improperly employed as the vehicle of substances to be applied by inunction. For this purpose lard should be used in winter, and simple ointment in summer; the cerate having too firm a consistence. W.

CERATUM ZINCI CARBONATIS. *U.S.* CERATUM CALAMINÆ. *Lond.* CERATUM CARBONATIS ZINCI IMPURI. *Ed.* UNGUENTUM CALAMINÆ. *Dub.* *Cerate of Carbonate of Zinc. Turner's Cerate.*

"Take of Prepared Carbonate of Zinc, Yellow Wax, each, *half a pound;* Lard *two pounds.* Melt the Wax and Lard together, and when upon cooling they begin to thicken, add the Carbonate of Zinc, and stir the mixture constantly until cool." *U.S.*

The *London College* orders half a pound of the carbonate of zinc, half a pound of yellow wax, and a pint of olive oil; the *Edinburgh,* one part of the carbonate and five parts of lard; the *Dublin,* one pound of the carbonate, and five pounds of ointment of yellow wax.

The process adopted in the last edition of our Pharmacopœia is preferable to that of the original edition, in which the proportion of calamine was much too large. This cerate is an imitation of that recommended by Turner. It is mildly astringent, and is much used in excoriations and superficial ulcerations, produced by the chafing of the skin, irritating secretions, burns, or other causes.

W.

CONFECTIONES. *U.S., Lond.*

Confections.

CONSERVÆ; ELECTUARIA. *Ed.* CONFECTIONES; CONSERVÆ; ELECTUARIA. *Dub.*

Under the general title of Confections, the Pharmacopœias of the United States and of London include all those preparations having the form of a soft solid, in which one or more medicinal substances are incorporated with saccharine matter, with a view either to their preservation or more convenient administration. The Edinburgh College retains the old division into Conserves and Electuaries; and, as there is some ground for the distinction, we shall make a few general remarks upon each division, before proceeding to the consideration of the individual preparations.

CONSERVES consist of recent vegetable substances and refined sugar beat into a uniform mass. By means of the sugar, the vegetable matter is enabled to resist for some time the decomposition to which it would otherwise be exposed in the undried state, and the properties of the recent plant are thus retained to a certain extent unaltered. But as active medicines even thus treated undergo some change, and those which lose their virtues by desiccation cannot be long preserved, the few conserves now retained are intended rather as convenient vehicles of other substances, than for separate exhibition. The sugar used in their preparation should be reduced to a fine powder by pounding and sifting, as otherwise it will not mix uniformly with the other ingredient.

ELECTUARIES are mixtures consisting of medicinal substances, especially dry powders, combined with syrup or honey, in order to render them less unpleasant to the taste, and more convenient for internal use. They are usually prepared extemporaneously; and it is only when their complex nature renders it convenient to keep them ready made in the shops, or some peculiarity in the mode of mixing the ingredients requires attention, that they become proper objects for pharmaceutic direction. Their consistence should not be so soft, on the one hand, as to allow the ingredients to separate, nor so firm, on the other, as to prevent them from being swallowed without mastication. Different substances require different proportions of syrup. Light vegetable powders usually require twice their weight, gum-resins two-thirds of their weight, resins somewhat less, mineral substances about half their weight, and deliquescent salts not more than one-tenth. Should the electuary be found, after having been kept for a short time, to swell up and emit gas, it should be beat over again in a mortar, so that any portion of the sugar which may have crystallized may be again accurately incorporated with the other ingredients. Should it on the contrary, become dry and hard, from the mutual reaction of its constituents, more syrup should be added, so as to give it the requisite consistence. If the dryness result from the mere evaporation of the aqueous part, water should be added instead of syrup; and the same remark is applicable to the conserves. To prevent the hardening of electuaries, the French writers recommend the use of syrup prepared from brown sugar, which is less apt to crystallize than that made from the refined. Molasses would answer the same purpose; but its taste might be considered objectionable. Some employ honey, but this is not always acceptable to the stomach. W.

CONFECTIO AMYGDALÆ. *U.S.* CONFECTIO AMYGDALARUM. *Lond., Dub.* *Almond Confection.*

"Take of Almonds [Sweet Almonds, *Lond., Dub.*] *an ounce;* Gum Arabic, in powder, *a drachm;* Sugar [refined] *half an ounce.* Having macerated the Almonds in water, and deprived them of their external coat, beat all the ingredients together till they are thoroughly mixed." *U.S., Lond., Dub.*

This preparation was introduced into the last edition of our Pharmacopœia, from that of London, as affording a speedy method of preparing the almond mixture, which when made immediately from the almonds requires much time, and which cannot be kept ready made in the shops. (See *Mistura Amygdalæ.*) The U.S. Pharmacopœia does not indicate the variety of almonds, whether sweet or bitter. The process will answer equally well for either; but the former should always be employed when the latter are not expressly ordered. W.

CONFECTIO AROMATICA. *U.S., Lond., Dub.* *Aromatic Confection.*

"Take of Aromatic Powder *an ounce;* Syrup of Orange Peel *two ounces.* Beat them together till they are thoroughly mixed." *U.S.*

The process of the *Edinburgh College* is essentially the same.

"Take of Cinnamon Bark, Nutmegs, each, *two ounces;* Cloves *an ounce;* Cardamom Seeds *half an ounce;* Saffron, dried, *two ounces;* Prepared Shells [Prepared Chalk, *Dub.*] *sixteen ounces;* Refined Sugar, in powder, *two pounds;* Water *a pint.* Rub the dry ingredients together to a very fine powder; then add the Water gradually, and mix till they are thoroughly incorporated." *Lond., Dub.*

The preparation of the United States Pharmacopœia contains cinnamon, ginger, and cardamom, without carbonate of lime, which appears to us to be an unnecessary if not improper ingredient, as it is not always indicated in cases which call for the use of the confection, and may be added extemporaneously when required. The aromatic confection affords a convenient method of administering the spices which enter into its composition. It is given in debilitated states of the stomach, alone or as an adjuvant to other medicines. The dose is from ten to sixty grains. W.

CONFECTIO AURANTII CORTICIS. *U.S.* CONFECTIO AURANTIORUM. *Lond.* CONSERVA CITRI AURANTII. *Ed.* *Confection of Orange Peel.*

"Take of Fresh Orange Peel, separated by grating, *a pound;* Sugar [refined] *three pounds.* Beat the Orange Peel with the Sugar gradually added, till they are thoroughly mixed." *U.S.*

The directions of the *London* and *Edinburgh Colleges* correspond with the above. By the London process, the beating is performed in a stone mortar with a wooden pestle.

This confection is sometimes used as a grateful aromatic vehicle or adjunct of tonic and purgative powders. W.

CONFECTIO CASSIÆ. *Lond.* ELECTUARIUM CASSIÆ FISTULÆ. *Ed.* ELECTUARIUM CASSIÆ. *Dub.* *Confection of Cassia.*

"Take of Fresh Cassia Pulp *half a pound;* Manna *two ounces;* Tamarind Pulp *an ounce;* Syrup of roses *half a pint.* Bruise the Manna, and dissolve it in the Syrup by means of a water-bath; then mix in the Pulps, and evaporate to a proper consistence." *Lond.*

The *Edinburgh College* orders four parts of the cassia pulp, one part of tamarind pulp, one part of manna, and four parts of the syrup of pale roses. The formula of the *Dublin College* corresponds with that of the London, except that syrup of orange peel is substituted for the syrup of roses.

The confection of cassia is slightly laxative; but is seldom if ever prepared in this country, and might very properly be expunged from the catalogue of Preparations, as it is both feeble and expensive. W.

ELECTUARIUM CATECHU COMPOSITUM. *Ed., Dub.* *Compound Electuary of Catechu.*

"Take of Extract of Catechu [Catechu] *four ounces;* Kino *three ounces;* Cinnamon Bark, Nutmegs, each, *an ounce;* Opium diffused in a sufficient quantity of Sherry Wine, *a drachm and a half;* Syrup of Red Roses boiled to the consistence of honey, *two pounds and a quarter.* Reduce the solids to powder; and mix them with the Opium and Syrup; so as to form an electuary." *Ed.*

"Take of Catechu *four ounces;* Cinnamon Bark *two ounces;* Kino *three ounces.* Rub these to powder and add of Turkey Opium diffused in Spanish White Wine, *a drachm and a half;* Syrup of Ginger, evaporated to the consistence of honey, *two pounds and a quarter.* Mix them." *Dub.*

These preparations do not essentially differ. They are aromatic and astringent, containing one grain of opium in about two hundred grains of the mass; and may be advantageously given in diarrhœa and chronic dysentery, in the dose of half a drachm or a drachm more or less frequently repeated. They may be taken in the form of bolus, or diffused in water. W.

CONFECTIO OPII. *U.S., Lond., Dub.* ELECTUARIUM OPIATUM *Ed.* *Confection of Opium.*

"Take of Opium, in powder, *six drachms;* Aromatic powder *six ounces;* Tragacanth, in powder, *two drachms;* Syrup *a pint.* Rub the Opium with the Syrup previously heated; then add the other ingredients, and beat the whole together till they are thoroughly mixed." *U.S.*

In the *London* and *Dublin* formulæ, an ounce of long pepper, two ounces of ginger, and three ounces of caraway seeds, all in powder, hold the place of the six ounces of aromatic powder directed by the U.S. Pharmacopœia. In other respects the processes are identical. The *Edinburgh College* directs six ounces of aromatic powder; three ounces of Virginia snake-root in fine powder; half an ounce of opium diffused in a sufficient quantity of sherry wine; and a pound of syrup of ginger.

This confection was intended as a substitute for those exceedingly complex and unscientific preparations which were formerly known by the names of *theriaca* and *mithridate*, and which have been expelled from modern pharmacy. It is a combination of opium with spices, which render it more stimulant, and more grateful to a debilitated stomach. It is given in atonic gout, flatulent colic, diarrhœa unattended with inflammation, and in various other diseases requiring the use of a stimulant narcotic. Added to Peruvian bark or sulphate of quinia it increases considerably the efficacy of this remedy in obstinate cases of intermittent fever. One grain of opium is contained in thirty-six grains of the confection prepared according to the U.S., London, and Dublin processes, and in forty-three grains of the Edinburgh electuary. W.

CONFECTIO PIPERIS NIGRI. *Lond., Dub.* *Confection of Black Pepper.*

"Take of Black Pepper, Elecampane, each, *a pound;* Fennel Seeds *three pounds;* Honey, Refined Sugar, each, *two pounds.* Rub the dry ingredients together into a very fine powder; then add the Honey, and beat the whole into a uniform mass." *Lond., Dub.*

This preparation was intended as a substitute for *Ward's paste*, which acquired some reputation in Great Britain as a remedy in piles. To do good, it must be continued, according to Mr. Brodie, for two, three, or four months. The dose is from one to two drachms repeated two or three times a day. Its stimulating properties render it inapplicable to cases attended with much inflammation. W.

CONFECTIO ROSÆ. *U.S.* CONFECTIO ROSÆ GALLICÆ. *Lond.* CONSERVA ROSÆ GALLICÆ. *Ed.* CONSERVA ROSÆ. *Dub.* *Confection of Roses. Conserve of Roses.*

"Take of Red Roses, unblown, *a pound;* Sugar [refined] *three pounds.* Bruise the Roses; then, gradually adding the Sugar, beat the two together till they are thoroughly mixed." *U.S.*

This process agrees with those of the three British Colleges. The *London College* directs the beating to be performed in a stone mortar. The unblown petals only are used, and these should be deprived of their claws; in other words, the rose buds should be cut off a short distance above their base, and the lower portion rejected.

This confection is slightly astringent, but is almost exclusively used as a vehicle of other medicines, or to impart consistence to the pilular mass.

Off. Prep. Pilulæ Hydrargyri, *U.S., Lond., Ed., Dub.* W.

CONFECTIO ROSÆ CANINÆ. *Lond.* CONSERVA ROSÆ CANINÆ. *Ed.* *Confection of the Dog-rose.*

"Take of Pulp of the Dog-rose *a pound;* Refined Sugar, in powder, *twenty ounces.* Expose the Pulp to a gentle heat by means of a water-bath; then add the Sugar gradually, and rub them together until they are thoroughly mixed." *Lond.*

"Beat the ripe Fruit of the Dog-rose, carefully cleansed from the seeds and down, to a pulp; and, while beating it, add gradually three times its weight of Refined Sugar." *Ed.*

This preparation is acidulous and refrigerant, and is used in Europe for forming more active medicines into pills and electuaries. W.

CONFECTIO RUTÆ. *Lond.* CONSERVA RUTÆ. *Dub.* *Confection of Rue.*

"Take of dried Rue Leaves, Caraway Seeds, Laurel Berries, each, *an ounce and a half;* Sagapenum *half an ounce;* Black Pepper *two drachms;* Clarified Honey *sixteen ounces.* Rub the dry ingredients together to a very fine powder; then add the Honey, and mix the whole together." *Lond.*, *Dub.*

The confection of rue is antispasmodic, and in Great Britain is employed in the form of enema in hysterical complaints and flatulent colic; but in this country it is not used. From a scruple to a drachm may be administered, diffused in half a pint of warm mucilaginous fluid. W.

CONFECTIO SCAMMONII. *U.S.* CONFECTIO SCAMMONEÆ. *Lond.* ELECTUARIUM SCAMMONII. *Dub.* *Confection of Scammony.*

"Take of Scammony, Ginger, each, in powder, *an ounce;* Oil of Cloves *twenty minims;* Syrup of Orange Peel *a sufficient quantity.* Rub together the Scammony and Ginger; then drop in the Syrup, and again rub them; lastly, add the Oil of Cloves, and beat the whole together, till they are thoroughly mixed." *U.S.*

The *London* and *Dublin Colleges* order an ounce and a half of powdered scammony; six drachms of bruised cloves; six drachms of powdered ginger; half a fluidrachm of oil of caraway; and a sufficient quantity of syrup of roses. The dry ingredients are first rubbed together to a very fine powder, then with the syrup gradually added, and lastly with the oil of caraway.

This confection is actively cathartic in the dose of half a drachm or a drachm; but is very little used. The proportion of scammony is uncertain, from the indefinite quantity of syrup employed. W.

CONFECTIO SENNÆ. *U.S.*, *Lond.* ELECTUARIUM SENNÆ COMPOSITUM. *Ed.* ELECTUARIUM SENNÆ. *Dub.* *Confection of Senna.* ELECTUARIUM LENITIVUM. *Lenitive Electuary.*

"Take of Senna *eight ounces;* Coriander [seed] *four ounces;* Liquorice Root, bruised, *three ounces;* Figs *a pound;* Pulp of Prunes, Pulp of Tamarinds, Pulp of Purging Cassia, each, *half a pound;* Sugar [refined] *two pounds and a half;* Water *four pints.* Rub the Senna and Coriander together, and separate ten ounces of the powder with a sieve. Boil the residue with the Figs and Liquorice Root, in the Water, to one half; then press out the liquor and strain it. Evaporate the strained liquor by means of a water-bath to a pint and a half; then add the Sugar and form a syrup. Lastly, rub the Pulps gradually with the syrup, and having thrown in the sifted powder, beat the whole together till they are thoroughly mixed." *U.S.*

The *London* process corresponds with the above. The *Edinburgh College* directs a pound of figs, and omits the cassia pulp. The *Dublin College* boils a pound of the pulp of prunes, and two ounces of the pulp of tamarinds, in a pint and a half of molasses, to the thickness of honey; then adds four ounces of senna in very fine powder, and, when the mixture cools, two drachms of oil of caraway; and, lastly, mixes the whole intimately.

The confection of senna, when properly made, is an elegant preparation. The pulp of purging cassia is most conveniently obtained by boiling the bruised pods in water, straining the decoction, and evaporating to the consistence of an electuary. The pulp of prunes may be prepared by boiling the fruit in a small quantity of water to soften it, then pressing it through a hair sieve, and evaporating to a proper consistence. The tamarinds, when too dry for immediate use, may be treated in the same manner. In each case, the evaporation should be completed by means of a water-bath, in order to prevent the pulps from being burnt. It is common to omit the cassia pulp in the preparation of the confection, as the pods are not always to be found in the market. But as this is next to senna the most active ingredient, the omission is to be regretted; and there is no doubt that a steady demand for the fruit would be met by an abundant supply from the West Indies.

This is one of our best and most pleasant laxatives, being admirably adapted to cases of habitual costiveness, especially in pregnant women and persons affected with piles. It is also very useful in the constipation which is apt to attend convalescence from fevers and other acute diseases. The mean dose is two drachms, to be taken at bed-time. W.

CUPRUM.

Preparations of Copper.

CUPRI ACETAS PRÆPARATUS. *U.S.* CUPRI SUBACETAS PRÆPARATUM. *Dub.* *Prepared Acetate of Copper.*

"Take of Acetate of Copper [verdigris] *any quantity.* Let it be prepared in the manner directed for Carbonate of Lime." *U.S.*

"Let the Subacetate of Copper be ground to powder, and the finer parts separated in the manner directed for the preparation of Chalk." *Dub.*

The object of this process is, by levigation and elutriation, to reduce verdigris to the state of a very fine powder. A chemical change is at the same time produced, which was not originally contemplated. Verdigris is an impure diacetate of copper, consisting of one equivalent of acid, two equiv. of protoxide, and six of water. By the action of water it is converted into the soluble neutral acetate and an insoluble triacetate. The latter, consisting of one equiv. of acetic acid, three equiv. of protoxide of copper, and one and a half of water, is the *Prepared Acetate of Copper* of the Pharmacopœia, which therefore differs from commercial verdigris in composition as well as in its state of aggregation. (See *Cupri Acetas.*) This preparation is used only as an escharotic and stimulant application to unhealthy ulcers and obstinate cutaneous eruptions.

Off. Prep. Oxymel Cupri Subacetatis, *Dub.*; Unguentum Cupri Acetatis, *U.S.*, *Dub.* W.

CUPRUM AMMONIATUM. *U.S.*, *Lond.*, *Dub.* AMMONIARETUM CUPRI. *Ed.* *Ammoniated Copper.*

"Take of Sulphate of Copper *half an ounce;* Carbonate of Ammonia *six drachms.* Rub them together in a glass mortar till the effervescence ceases; then wrap the Ammoniated Copper in bibulous paper, and dry it with a gentle heat. Let it be kept in a well stopped glass bottle." *U.S.*

The processes of the British Colleges are essentially the same as the above, the ingredients, proportions, and general mode of operating being identical. The *London College* omits the direction as to the mode of keeping the preparation; the *Edinburgh* directs that the product, after being wrapped in bibulous paper, should be dried first on a chalk stone, and afterwards by a gentle heat; and the *Dublin* orders the ingredients to be triturated in an earthenware mortar.

When the two salts above mentioned are rubbed together, a reaction takes place between them, attended with the extrication of the water of crystallization of the sulphate of copper, which renders the mass moist, and the simultaneous escape of carbonic acid gas from the carbonate of ammonia, which occasions an effervescence. The colour is at the same time altered, passing from the light blue of the powdered sulphate of copper to a beautiful deep azure. The nature of the chemical changes which take place is not precisely known. The blue vitriol parts with a portion of its acid to the ammonia of the carbonate, thus forming a subsulphate of copper and sulphate of ammonia, which are either mixed together, or, what is more probable, chemically united in the form of a double salt. With this view of its nature, the preparation might be called a sulphate of copper and ammonia, and considered identical with the crystallized salt, obtained by dropping a solution of pure ammonia into a solution of sulphate of copper till the subsalt first thrown down is dissolved, then concentrating, and precipitating by alcohol. But the ammonia of the carbonate employed in the process for preparing the ammoniated copper, is much more than sufficient to saturate the whole of the sulphuric acid of the sulphate of copper; and it is probable, therefore, that there is in the preparation an excess of carbonate of ammonia, which varies according to the temperature employed in drying the medicine. It is not, indeed, impossible, that, as stated by Brande, a carbonate of copper and ammonia may be among its constituents. In this uncertainty as to its precise nature, the name of *ammoniated copper* appears to be as appropriate for a pharmaceutical title as any that could be adopted.

This salt is of a fine blue colour, which on exposure becomes green, in consequence probably of the escape of ammonia. This change is apt to take place to a greater or less extent while it is drying; and it should not, therefore, be prepared in large quantities at a time, and should be carefully excluded from the air. It has the odour of ammonia, and a styptic, metallic taste. It is soluble in water; but, according to Mr. Phillips, is decomposed by this fluid when used in very large proportion. Potassa, lime-water, and the acids are incompatible with it.

Medical Properties and Uses. Ammoniated copper is tonic, and has been much employed in epilepsy, in which it was recommended by Cullen. There is good reason to believe that it has occasionally effected cures; but like all other remedies in that complaint it very frequently fails. It has also been used in chorea, hysteria, and worms; and by Swediaur as an injection in gonorrhœa and leucorrhœa. In over-doses it produces vomiting, and the poisonous effects which result from the other preparations of copper. (See *Cuprum.*) It is said, however, to be less apt to excite nausea. The dose is a quarter or half a grain, repeated twice a day, and gradually increased to four or five grains. It may be given in pill or solution. The medicine should not be very long continued without interruption; according to Cullen, not longer than a month.

Off. Prep. Liquor Cupri Ammoniati, *Lond.*, *Dub.* W.

LIQUOR CUPRI AMMONIATI. *Lond.* CUPRI AMMONIATI AQUA. *Dub.* *Solution of Ammoniated Copper.*

"Take of Ammoniated Copper *a drachm;* Distilled Water *a pint.* Dissolve the Ammoniated Copper in the Water, and filter through paper." *Lond.*

The *Dublin College* employs one part of the salt to one hundred parts of distilled water.

By the quantity of water employed in these processes, the ammoniated copper, unless it contain an excess of carbonate of ammonia, is said by Mr. Phillips to be decomposed, with a precipitation of one-half of the oxide of copper. According to the same author, a smaller portion of water dissolves it perfectly.

This solution is sometimes employed as a stimulant to foul and indolent ulcers, and, diluted with water, as an application to the cornea when affected with specks or opacity; but it is probably in no respect superior for these purposes to the solution of sulphate of copper, and scarcely deserves a place among the officinal preparations. W.

SOLUTIO SULPHATIS CUPRI COMPOSITA. *Ed.* *Compound Solution of Sulphate of Copper.*

"Take of Sulphate of Copper, Alum, each, *three ounces;* Water *two pounds;* Sulphuric Acid *an ounce and a half.* Boil the Sulphates in the Water that they may be dissolved; and then to the liquor filtered through paper add the Acid." *Ed.*

No chemical reaction takes place between the ingredients of this solution, which might with great propriety be left to extemporaneous prescription. It has been used chiefly as a styptic to arrest hemorrhages, being applied to the bleeding surface by means of dossils of lint. It has been employed also in the purulent ophthalmia of infants, largely diluted with water. W.

◆

DECOCTA.

Decoctions.

Decoctions are solutions of vegetable principles, obtained by boiling the substances containing these principles in water. Vegetables generally yield their soluble ingredients more readily and in larger proportion to water maintained at the point of ebullition, than to the same liquid at a lower temperature. Hence decoction is occasionally preferred to infusion as a mode of extracting the virtues of plants, when the call for the remedy is urgent, and the greatest possible activity in the preparation is desirable. The process should be conducted in a covered vessel, so as to confine the vapour over the surface of the liquid, and thus prevent the access of atmospheric air, which sometimes exerts an injurious agency upon the active principle. The boiling, moreover, should not, as a general rule, be long continued; as the ingredients of the vegetable are apt to react on each other, and thus lose, to a greater or less extent, their original character. The substance submitted to decoction, should if dry be either powdered or well bruised, if fresh should be sliced, so that it may present an extensive surface to the action of the solvent; and previous maceration for some time in water is occasionally useful by overcoming the cohesion of the vegetable fibre.

All vegetable substances are not proper objects for decoction. In many the active principle is volatile at a boiling heat, in others it undergoes some change unfavourable to its activity, and in a third set is associated with inefficient or nauseous principles, which, though insoluble or but slightly soluble in cool water, are abundantly extracted by that liquid at the boiling temperature, and thus encumber, if they do not positively injure the preparation. In all these instances, infusion is preferable to decoction. Besides, by the latter process, more matter is often dissolved than the water can retain in solution, so that upon cooling a precipitation takes place, and the liquid is rendered turbid. When the active principle is thus dissolved in excess, the decoction should always be strained while hot, so that the matter which separates on cooling, may be mixed again with the fluid by agitation at the time of administering the remedy.

In compound decoctions; the ingredients may be advantageously added at different periods of the process, according to the length of boiling requisite for extracting their virtues; and, should any one of them owe its activity to a volatile principle, the proper plan is, at the close of the process, to pour upon it the boiling decoction, and allow the liquor to cool in a covered vessel.

Decoctions, from the mutual reaction of their constituents, as well as from the influence of the air, are apt to spoil in a short time. Hence they should be prepared only when wanted for use, and should not be kept, in warm weather, for a longer period than forty-eight hours. W.

DECOCTUM ALOES COMPOSITUM. *Lond., Dub. Compound Decoction of Aloes.*

"Take of Extract of Liquorice *half an ounce;* Subcarbonate of Potassa *two scruples;* Socotrine Aloes in powder, Myrrh in powder, Saffron, each, *a drachm;* Compound Tincture of Cardamom *four fluidounces;* Water *a pint.* Boil the Liquorice, Subcarbonate of Potassa, Aloes, Myrrh, and Saffron with the Water, to twelve fluidounces; then strain and add the Compound Tincture of Cardamom." *Lond.*

The *Dublin* process differs only in the use of Hepatic instead of Socotrine Aloes.

The effect of the alkaline carbonate is, by combining with the resinous ingredient (apotheme, *Berzelius,*) of the aloes, to render it more soluble in water, while the liquorice assists in the suspension of the portion not actually dissolved. The tincture of cardamom is useful not only by its cordial property, but also by preventing spontaneous decomposition.

Long boiling impairs the purgative property of aloes; and the same effect is thought to be produced, to a certain extent, by the alkalies, which certainly qualify its operation, and render it less apt to irritate the rectum. This decoction, therefore, is milder as a cathartic than aloes itself, and not so liable to produce or aggravate hemorrhoidal disease. At the same time it is more tonic and cordial from the presence of the myrrh, saffron, and cardamom, and derives antacid properties from the carbonate of potassa. It is given as a gentle cathartic, tonic, and emmenagogue; and is especially useful in dyspepsia, habitual constipation, and those complicated cases, in which suppressed or retained menstruation is connected with enfeebled digestion and a languid state of bowels. The dose is from half a fluidounce to two fluidounces.

It should not be combined in prescription with acids, acidulous salts, or other saline bodies which are incompatible with the alkaline carbonate employed in its preparation. W.

DECOCTUM ALTHÆÆ. *Dub.* DECOCTUM ALTHÆÆ OFFICINALIS. *Ed. Decoction of Marsh Mallow.*

"Take of the Herb and Root of Marsh Mallow, dried and bruised, *four ounces;* Raisins, stoned, *two ounces;* Water *seven pints.* Boil down to five pints, and strain the liquor; then set it by till the dregs have subsided, and decant." *Dub.*

The *Edinburgh College* orders the roots only of the marsh mallow, and seven pounds of water.

This decoction is a simple mucilage flavoured with raisins; and may be used advantageously as a drink, in all cases in which demulcents are indicated. W.

DECOCTUM ANTHEMIDIS NOBILIS. *Ed.* DECOCTUM CHAMÆMELI COMPOSITUM. *Dub. Decoction of Chamomile.*

"Take of dried Chamomile Flowers *an ounce;* Caraway Seeds, bruised, *half an ounce;* Water *five pounds.* Boil for a quarter of an hour, and strain." *Ed.*

"Take of dried Chamomile Flowers *half an ounce;* Fennel Seeds *two drachms;* Water *a pint.* Boil for a short time, and strain." *Dub.*

In preparing these decoctions, the aromatic should not be added till near the end of the process. They contain the bitter extractive of the chamomile, with little of its peculiar aroma, which is dissipated by the boiling. They are inferior, therefore, for internal use, to the infusion; and are calculated only for fomentations and enemata. W.

DECOCTUM CINCHONÆ. *U.S., Lond., Dub.* DECOCTUM CINCHONÆ LANCIFOLIÆ. *Ed.* *Decoction of Peruvian Bark.*

"Take of Peruvian Bark, bruised, *an ounce;* Water *a pint.* Boil for ten minutes in a covered vessel, and strain the liquor while hot." *U.S.*

The British Colleges particularize the pale bark as the variety to be employed. The *London* process is identical with ours. The *Edinburgh* differs only in the quantity of water, which is a pound and a half instead of a pint. The *Dublin College*, without specifying the length of boiling, orders an ounce of the bark, in coarse powder, and enough water to yield a pint of the strained decoction.

As the red and yellow barks are certainly not less efficient than the pale, nor less adapted for decoction, we can discover no reason for restricting the process to one variety, and therefore decidedly prefer the American formula, which leaves to the physician the liberty of choice.

The virtues of Peruvian bark, though extracted more rapidly by decoction than by infusion, are materially impaired by long boiling, in consequence of the changes effected in its constituents, either by their mutual reaction, or by the agency of atmospheric oxygen, or by both causes united. To prevent this result, the process is directed to be performed in a covered vessel, and to continue only ten minutes. But even with these precautions a considerable precipitate takes place in the decoction upon cooling, which is thus rendered turbid. According to Pelletier, besides the kinates of cinchonia and quinia, the water dissolves gum, starch, yellow colouring matter, kinate of lime, tannin, and a portion of cinchonic red, with a minute quantity of fatty matter. But the tannin and starch, at the boiling temperature, unite to form a compound insoluble in cold water; and, when the decoction is allowed to cool, this compound is precipitated, together with a portion of the cinchonic red and fatty matter, which carry with them also a considerable quantity of the alkaline principle of the bark. (*Journ. de Pharm.* vii. 119.) Hence the decoction is ordered to be strained while hot, so that the portion of active matter precipitated may be mingled by agitation with the liquor, and not be lost. Pelletier recommends that a larger proportion of water, sufficient to retain the alkali in solution, be employed, that the decoction be filtered when cold, and then sufficiently concentrated by evaporation. But this process would be unnecessarily tedious. A better plan is to add to the liquid some acid which may form with the quinia and cinchonia compounds more soluble than the native salts. Lemon juice has been long employed as a useful addition to the decoction of cinchona, and we can now understand the manner in which it acts. Sulphuric acid in excess answers the same purpose. By acidulating the pint of water employed in preparing the decoction with one fluidrachm of the aromatic or diluted sulphuric acid, we shall probably enable the menstruum to extract all the virtues of the bark. The propriety of such an addition is confirmed by the experiments of *MM.*

Henry Jun. and *Plisson*, who have ascertained that portions of the alkalies exist in the bark connected with the colouring matter in the form of insoluble compounds, and that it is impossible, therefore, completely to exhaust the bark by water alone. There may, however, be some diversity of action between the different salts of quinia and cinchonia; and the native kinates may under certain circumstances be most efficient.

As the bark is never completely exhausted by decoction in the ordinary way, it has been proposed to employ the residue for the extraction of quinia or cinchonia; but this could be done advantageously only in hospitals or great public establishments, where large quantities of the preparation are employed.

Numerous substances produce precipitates with this decoction; but comparatively few affect its activity as a medicine. (See *Infusum Cinchonæ.*) Gallic, oxalic, and tartaric acids, and the substances containing them, should be excluded from the decoction, as they form salts with the alkaline principles of the bark, which are but slightly soluble in water. The alkalies, alkaline earths, and salifiable bases generally, should also be excluded, because, uniting with the kinic acid, they precipitate the quinia and cinchonia.

The dose of the decoction is two fluidounces, to be repeated more or less frequently according to circumstances. Two drachms of orange peel added to the decoction while still boiling hot, improve its flavour, and render it more pleasant to the stomach. W.

DECOCTUM CORNUS FLORIDÆ. *U.S.* *Decoction of Dogwood.*

"Take of Dogwood [bark], bruised, *an ounce;* Water *a pint.* Boil for ten minutes in a covered vessel, and strain the liquor while hot." *U.S.*

This decoction has been proposed as a substitute for that of Peruvian bark; but, though possessed of analogous properties, it is much inferior in efficacy, and is not likely to be extensively employed so long as the Peruvian tonic is attainable. The dose is two fluidounces. W.

DECOCTUM CYDONIÆ. *Lond.* *Decoction of Quince Seeds.*

"Take of Quince Seeds *two drachms;* Water *a pint.* Boil over a slow fire for ten minutes; then strain." *Lond.*

This decoction is viscid, nearly colourless, insipid, and inodorous; and consists chiefly of the mucilaginous principle of the quince seeds dissolved in water. For an account of the properties and uses of this mucilage see *Cydoniæ Semina.* The decoction speedily undergoes decomposition, and should, therefore, be used immediately after being prepared. W.

DECOCTUM DULCAMARÆ. *U.S., Lond., Dub.* *Decoction of Bittersweet.*

"Take of Bittersweet, bruised, *an ounce;* Water *a pint and a half;* Boil down to a pint and strain." *U.S.*

The processes of the British Colleges correspond with the above.

The slender twigs of the bittersweet are the part employed. Their properties and uses have been already detailed under the head of Dulcamara. The dose of the decoction is from one to two fluidounces three or four times a day. W.

DECOCTUM GEOFFROYÆ. *Dub.* DECOCTUM GEOFFRÆÆ INERMIS. *Ed.* *Decoction of Cabbage-tree Bark.*

"Take of Cabbage-tree Bark, bruised, *an ounce;* Water *two pints.* Boil down to a pint, and to the strained liquor add *two ounces* of the Syrup of Orange Peel." *Dub.*

"Take of Cabbage-tree Bark, in powder, *an ounce;* Water *two pounds.* Boil with a gentle fire down to one pound, and strain." *Ed.*

This decoction has the colour of Madeira wine. It is powerfully anthelmintic, and is a popular remedy in the West Indies. The disagreeable effects which are said to arise from an over-dose, or from drinking cold water during its operation, may be counteracted, according to Dr. Wright, by washing out the stomach with warm water, purging with castor oil, and administering lemonade freely. The dose for an adult is two fluidounces, for a child two or three years old, half a fluidounce, to be gradually increased at each successive administration till it produces nausea. W.

DECOCTUM GLYCYRRHIZÆ. *Dub. Decoction of Liquorice Root.*

"Take of Liquorice Root, bruised, *an ounce and a half;* Water *a pint.* Boil for ten minutes, and strain." *Dub.*

This decoction may be used as a demulcent beverage, or as a vehicle for medicines of unpleasant flavour. W.

DECOCTUM GUAIACI COMPOSITUM. *Ed., Dub. Compound Decoction of Guaiacum Wood.*

"Take of Guaiacum Wood, rasped, *three ounces;* Raisins *two ounces;* Sassafras Root, sliced, Liquorice Root, bruised, each, *an ounce;* Water *ten pounds.* Boil the Guaiacum Wood and Raisins with the Water down to five pounds, adding, towards the end of the process, the Sassafras and Liquorice Root; then strain." *Ed.*

"Take of Guaiacum Wood, rasped, *three ounces;* Sassafras Root, sliced, *ten drachms;* Liquorice Root, bruised, *two ounces and a half;* Water *ten pints.* Boil the Guaiacum Wood in the Water down to one half; near the end of the boiling add the Liquorice and Sassafras, and strain the liquor." *Dub.*

This is the old *decoction of the woods.* Notwithstanding its former reputation, it is little more than a demulcent drink; for water is capable of dissolving but a minute proportion of the active matter of guaiacum wood, and one ounce of sassafras root can impart no appreciable activity to five pints of menstruum. It was thought useful in chronic rheumatism and cutaneous affections, and as an adjuvant to a mercurial course in syphilis, or an alterative course of antimonials. As the patient was directed to be kept warm during its use, it no doubt acted favourably in some instances as a mere diluent, by promoting perspiration. From one to two pints may be taken in the course of the day, in doses of about four fluidounces. W.

DECOCTUM HÆMATOXYLI. *U.S. Decoction of Logwood.*

"Take of Logwood, rasped, *an ounce;* Water *two pints.* Boil down to a pint, and strain." *U.S.*

This is an excellent astringent in diarrhœa, particularly in that form of it which succeeds the cholera infantum of this climate, or occurs as an original complaint in children during summer. The dose for an adult is two fluidounces, for a child about two years old, two fluidrachms, repeated several times a day. A little bruised cinnamon may often be added with advantage at the end of the boiling. W.

DECOCTUM HORDEI. *U.S., Lond., Dub.* DECOCTUM HORDEI DISTICHI. *Ed. Decoction of Barley.*

"Take of [Pearl] Barley *two ounces;* Water *four pints and a half.* First wash away, with cold water, the extraneous matters which adhere to the Barley; then pour upon it half a pint of the Water, and boil for a short time. Having thrown away this water, pour the remainder boiling hot upon the Barley; then boil down to two pints, and strain." *U.S.*, *Lond.*

The processes of the *Edinburgh* and *Dublin Colleges* do not essentially differ from the above.

Barley water, as this decoction is usually called, is much employed as a nutritive drink in febrile and inflammatory complaints, and, from the total absence of irritating properties, is peculiarly adapted to cases in which the gastric or intestinal mucous membrane is inflamed. As the stomach of those for whom it is directed is often exceedingly delicate, and apt to revolt against any thing having the slightest unpleasantness of flavour, it is important that the decoction should be properly made; and though the office of preparing it generally falls to nurses, yet the introduction of the process into the Pharmacopœia is not without advantage, as a formula is thus ever before the physician, by which he may give his directions, with the certainty, if obeyed, of having a good preparation. The use of the washing with cold water, and of the first short boiling, is completely to remove any mustiness, or other disagreeable flavour, which the barley may have acquired from exposure.

W.

DECOCTUM HORDEI COMPOSITUM. *Lond.*, *Dub.* *Compound Decoction of Barley.*

"Take of Decoction of Barley *two pints;* Figs, sliced, *two ounces;* Liquorice Root, sliced and bruised, *half an ounce;* Raisins, stoned, *two ounces;* Water *a pint.* Boil down to two pints, and strain." *Lond.*

"Take of Decoction of Barley *four pints;* Raisins, stoned, Figs, sliced, each, *two ounces;* Liquorice Root, sliced and bruised, *half an ounce.* During the boiling, add first the Raisins, then the Figs, and lastly the Liquorice Root a short time before it is finished, when the strained decoction ought to measure two pints." *Dub.*

We prefer the London process, as it preserves the original strength of the simple decoction, which, according to the Dublin process, is, without any good reason that we can discover, concentrated to one half of its former bulk by evaporation. The compound decoction, in addition to the demulcent and nutritive properties of the simple, is somewhat laxative, and may be preferably employed where there is a tendency to constipation. But it is so often necessary to vary the nature of the sapid ingredients to suit the taste of the patient, that it would be better to leave the preparation entirely to extemporaneous prescription; and the process has been accordingly omitted in the last edition of the U.S. Pharmacopœia. W.

DECOCTUM LICHENIS. *U.S.*, *Lond.* DECOCTUM LICHENIS ISLANDICI. *Ed.*, *Dub.* *Decoction of Iceland Moss.*

"Take of Iceland Moss *an ounce;* Water *a pint and a half.* Boil down to a pint, and strain with compression." *U.S.*

The process of the *London College* corresponds with ours. The *Edinburgh College* orders an ounce of the moss with two pounds of water to be boiled to sixteen ounces, and strained. By the *Dublin* process, half an ounce of the moss is digested for two hours in a close vessel with a pint of boiling water, then boiled for fifteen minutes, and the liquor strained while hot.

As the bitter principle is dissolved along with the starch of the lichen, this decoction unites an unpleasant flavour to its demulcent properties; but the plan which has been proposed of first extracting the bitterness by maceration in water, or a very weak solution of an alkaline carbonate, and afterwards preparing the decoction, is inadmissible; as the peculiar virtues which distinguish the medicine from the ordinary demulcents are thus entirely lost. (See *Lichen.*) A pint of the decoction may be taken in divided doses during the twenty-four hours. W.

DECOCTUM MALVÆ COMPOSITUM. *Lond.* *Compound Decoction of Mallows.*

"Take of dried Mallows *an ounce;* dried Chamomile Flowers *half an ounce;* Water *a pint.* Boil for a quarter of an hour, and strain." *Lond.*

This is intended only for fomentations and enemata. W.

DECOCTUM MEZEREI. *Dub.* DECOCTUM DAPHNES MEZEREI. *Ed.* *Decoction of Mezereon.*

"Take of Bark of Mezereon Root *two drachms;* Liquorice Root, bruised, *half an ounce;* Water *three pounds.* Boil with a gentle fire down to two pounds, and strain." *Ed.*

The *Dublin* process is essentially the same.

This preparation affords a convenient mode of exhibiting mezereon, the acrimony of which is qualified by the demulcent principles of the liquorice root. For an account of its medical application, see *Mezereum.* The dose is from four to eight fluidounces four times a day. W.

DECOCTUM PAPAVERIS. *Lond., Dub.* *Decoction of Poppy.*

"Take of White Poppy Capsules, sliced, *four ounces;* Water *four pints* [two pints, *Dub.*]. Boil for a quarter of an hour, and strain." *Lond.*

This decoction is used as an anodyne fomentation in painful tumours and superficial cutaneous inflammation or excoriation. It is recommended not to reject the seeds, as their oil, suspended in the water by the mucilage of the capsules, adds to the emollient virtues of the preparation. W.

DECOCTUM PYROLÆ. *Dub.* *Decoction of Pipsissewa or Winter Green.*

"Take of Pipsissewa *an ounce;* Water *two pints.* Macerate for six hours; then take out the Pipsissewa, and having bruised it, return it to the liquor, and evaporate until only enough remains to afford one pint of decoction strained with expression." *Dub.*

The pipsissewa, or winter green, has been introduced into the U.S. Pharmacopœia by the name of *Chimaphila,* which is now the recognised generic title of the plant. Under this head, in the Materia Medica, the reader will find an account of the uses of the medicine. In this country it is almost always possible to obtain the fresh leaves, with which the decoction may be prepared without the previous maceration, directed by the Dublin College. One pint may be taken in the course of twenty-four hours. W.

DECOCTUM QUERCUS. *Lond., Dub.* DECOCTUM QUERCUS ROBORIS. *Ed.* *Decoction of Oak Bark.*

"Take of Oak Bark *an ounce;* Water *two pints.* Boil down to a pint, and strain." *Lond., Dub.*

The *Edinburgh College* directs two pounds and a half of water, and boils to sixteen ounces.

This decoction contains the tannin, extractive, and gallic acid of oak bark. It affords precipitates with the decoction of Peruvian Bark, solution of gelatin, and with most metallic salts, particularly those of iron. Alkaline solutions diminish or destroy its astringency. Its uses have been already detailed. The dose is a wineglassful, frequently repeated. W.

DECOCTUM SARSAPARILLÆ. *U.S., Lond., Dub.* DECOCTUM SMILACIS SARSAPARILLÆ. *Ed.* *Decoction of Sarsaparilla.*

"Take of Sarsaparilla, sliced and bruised, *six ounces;* Water *six pints.* Boil down to four pints, and strain." *U.S.*

"Take of Sarsaparilla Root, sliced, *four ounces;* Boiling Water *four pints.* Macerate for four hours in a covered vessel, near the fire; then take out the Sarsaparilla and bruise it. Put it again into the liquor, and macerate it in the same manner for two hours more; then boil down to two pints, and strain." *Lond.*

The *Dublin* process differs from that of the London College only in the omission of the second maceration.

"Take of the Root of Sarsaparilla, sliced, *six ounces;* Water *eight pounds.* Digest for two hours with a heat of about 195°; then take out the Root, and having bruised it, return it to the liquor, boil down to four pounds, express and strain the decoction." *Ed.*

Of these processes we decidedly prefer that of the U.S. Pharmacopœia, both for its greater simplicity, and for the shorter continuance of the boiling. There can be no occasion for the maceration directed by the British Colleges; as, if the root is sliced and well bruised, all its ingredients that are soluble in water may be extracted by a length of boiling sufficient to reduce the liquor to one-half. An idea was formerly entertained that the virtues of sarsaparilla resided in its fecula, the extraction of which was, therefore, the main object of the decoction. Hence the long boiling ordered by the Colleges. But this opinion is now admitted to be erroneous. The activity of the root is believed to depend upon one or more acrid principles, soluble to a certain extent in water cold or hot, and either volatilized, or rendered inert by chemical change, at the temperature of 212°. This fact appears to be demonstrated by the experiments of Pope,* Hancock,† Soubeiran,‡ and others. Hancock makes the following observations. "After long boiling, the peculiar odour which rises abundantly on the coction of good *sarsa*, is almost extinguished. From the sarsa prepared in this way I found no sensible results upon any patient, nor were its peculiar nauseating, drowsy, and racking effects produced by a large quantity, although the decoction of six or eight ounces was tried at a dose. These experiments having been carried to a sufficient length, most of the same patients recovered under the use of the sarsa, taken from the same parcels as before, but now prepared by simple maceration in hot water, *i.e.* affused in a boiling state, and kept near the boiling state for some hours. In all cases the sarsa was directed to be well bruised in large mortars, and in the mean time all other remedies were abstained from, which might, in any way, affect the result." M. Soubeiran macerated one portion of bruised sarsaparilla in cold water for twenty-four hours; infused another portion in boiling water, and digested with a moderate heat for two hours: boiled a third portion bruised, and a fourth unbruised, in water for two hours; and in each instance used the same relative quantities. Testing these various preparations by the taste, he found the cold and hot infusion scarcely different in this respect; and both possessed of a stronger odour and more acrid taste than the decoctions, of which that prepared with the bruised root was the strongest. From all these facts the inference is obvious, that the best method of imparting the virtues of sarsaparilla to water, is either by cold or hot infusion. Digestion for some hours in water maintained at a temperature of 180° or somewhat less, in a covered vessel, has the greatest weight of testimony in its favour. Decoction is the worst method; and the longer it is continued the weaker will be the preparation. The process of the U.S. Pharmacopœia, which reduces the liquor only one-third by boiling, is therefore superior to those of the British Colleges, which reduce it one-half. It is probable that, as in the case of the Peruvian bark, a boiling of ten or fifteen minutes might be advantageously resorted to, when circumstances require the preparation to be made in less time than is requisite for infusion. In every instance the root should be thoroughly bruised, or reduced to a coarse powder, thus obviating the necessity for a long maceration, merely to overcome the cohesion of its fibres.

---

* Trans. of the Medico-Chirurg. Society of Lond. vol. xii. p. 344.

† Trans. of the Medico-Botan. Society of Lond. See also Journ. of the Phil. Col. of Pharm. vol. i. p. 295. The observations of Dr. Hancock are entitled to much credit, as he practised long in South America, in the neighbourhood of the best sarsaparilla regions.

‡ Journ. de Pharmacie, tom. xvi. p. 38.

Precipitates are produced by various substances with the decoction of sarsaparilla; but it has not been ascertained how far such substances interfere with its activity. Those which merely throw down the fecula do not injure the preparation.

The simple decoction of sarsaparilla is chiefly used in the preparation of the compound decoction. If given alone, it may be administered in the dose of four or six fluidounces four times a day. W.

DECOCTUM SARSAPARILLÆ COMPOSITUM. *U.S.*, *Lond.*, *Dub.* *Compound Decoction of Sarsaparilla.*

"Take of Decoction of Sarsaparilla, boiling hot, *four pints;* Bark of Sassafras Root, sliced, Guaiacum Wood, rasped, Liquorice Root, bruised, each, *an ounce;* Mezereon, sliced, *three drachms.* Boil for a quarter of an hour, and strain." *U.S.*

The *London* and *Dublin* processes are the same with the above, except that sassafras root is directed instead of the bark of the root.

This decoction is an imitation of the celebrated *Lisbon diet drink.* The sarsaparilla and mezereon are the active ingredients; the guaiacum wood imparting scarcely any of its virtues; and the sassafras and liquorice serving little other purpose than to communicate a pleasant flavour.

A better plan of preparing this decoction, is to substitute for the four pints of decoction of sarsaparilla, six ounces of the root itself, thoroughly bruised or coarsely powdered, and four pints of water; and to allow the ingredients, after the completion of the boiling, to remain in a covered vessel in a warm place for two or three hours before straining. The boiling of fifteen minutes, and the subsequent maceration, would probably be sufficient to extract all the virtues of the sarsaparilla, which water alone, in the proportion indicated, is capable of taking up.

If prepared with good sarsaparilla, and with a due regard to the practical rules which may now be considered as established, this decoction may be used with great advantage as a gentle diaphoretic and alterative in secondary syphilis, either alone, or as an adjuvant to a mercurial course; also in certain scrofulous and other depraved conditions of the system, in chronic rheumatism, and in various obstinate cutaneous affections. The dose is from four to six fluidounces three or four times a day. The patient during its use should wear flannel next the skin, and avoid unnecessary exposure to changes of temperature. W.

DECOCTUM SENEGÆ. *U.S.*, *Lond.*, *Dub.* DECOCTUM POLYGALÆ SENEGÆ. *Ed.* *Decoction of Seneka.*

"Take of Seneka, bruised, *an ounce;* Water *two pints.* Boil down to a pint, and strain." *U.S.*, *Lond.*

The *Edinburgh College* directs two pounds of water, to be boiled down, with an ounce of Seneka, to sixteen ounces; the *Dublin*, a pint and a half of water, with three drachms of the root, to eight ounces.

It is customary to add to the seneka an equal weight of liquorice root, which serves to cover its taste, and in some measure to obtund its acrimony. The virtues and practical application of seneka have been already treated of. The dose of the decoction is about two fluidounces three or four times a day. W.

DECOCTUM TARAXACI. *Dub.* *Decoction of Dandelion.*

"Take of the Fresh Herb and Root of Dandelion *four ounces;* Water *two pints.* Boil down to a pint, and strain the expressed liquor." *Dub.*

This decoction would be more efficient if prepared from the root alone. The dose is a wineglassful two or three times a day. (See *Taraxacum.*) W.

DECOCTUM ULMI. *Lond., Dub.* DECOCTUM ULMI CAMPESTRIS. *Ed.* *Decoction of Elm Bark.*

"Take of Fresh Elm Bark, bruised, *four ounces;* Water *four pints.* Boil down to two pints, and strain." *Lond.*

The *Edinburgh College* orders four ounces of the bark and five pounds of water to be reduced by boiling to two pounds and a half. The *Dublin* process corresponds in its proportions with the London.

This decoction, being prepared from the bark of the European elm, is not used in this country. It had some repute in England as a remedy for certain cutaneous disorders; but has fallen into discredit. From four to six fluidounces were given two or three times a day. W.

DECOCTUM UVÆ URSI. *U.S.* *Decoction of Uva Ursi.*

"Take of Uva Ursi *an ounce;* Water *twenty fluidounces.* Boil down to a pint, and strain." *U.S.*

This decoction contains the tannin, extractive, and gallic acid of the leaves. For an account of its uses see *Uva Ursi.* The dose is from one to two fluidounces three or four times a day. W.

DECOCTUM VERATRI ALBI. *U.S.* DECOCTUM VERATRI. *Lond., Dub.* *Decoction of White Hellebore.*

"Take of White Hellebore, in powder, *an ounce;* Water *two pints;* Alcohol *two fluidounces.* Pour the Water upon the Hellebore and boil down to a pint; then strain the decoction, and after it has cooled add the Alcohol." *U.S.*

The *London* and *Dublin* processes correspond with the above.

The root of the white hellebore imparts its acrid properties to boiling water, and the decoction is powerfully cathartic and emetic; but, in consequence of the harshness of its action, it is not used internally. As an external application it is employed in psora, tinea capitis, lepra, and other cutaneous eruptions, in which it sometimes proves highly beneficial. When the skin is very irritable, it should be diluted with an equal measure of water. Even externally applied it should be used with some caution; as the veratria, upon which its activity depends, may possibly be absorbed. As the plant is not a native of this country, the *Veratrum viride*, which is identical in medical properties, may be advantageously substituted for it in the preparation of the decoction. W.

EMPLASTRA.

Plasters.

Plasters are solid compounds intended for external application, adhesive at the temperature of the human body, and of such a consistence as to render the aid of heat necessary in spreading them. Most of them have as their basis a compound of olive oil and litharge, constituting the Emplastrum Plumbi of the United States Pharmacopœia; and it has been proposed by M. Deyeux to restrict the term plaster to those bodies which are formed by the mutual reaction of the metallic oxides and oil or fat. But this proposition has not been adopted; and as the object of nomenclature is practical utility, there is an obvious propriety in retaining under the same officinal title, substances which, though differing in composition, are closely allied in all that relates to their pharmaceutic management. Those plasters which contain none of the compound of oil and litharge, owe their consistence and adhesiveness to resinous substances, or to a mixture of these with wax and oleaginous matter. Only two of this class have gained admission into our national Pharmacopœia; several of those directed by the British Colleges having been rejected as superfluous, and the Emplastrum Cantharidis transferred to the Cerates, to which class it properly belongs.

In the preparation of the plasters, care is requisite that the heat employed be not sufficiently elevated to produce decomposition, nor so long continued as to drive off any volatile ingredient upon which the virtues of the preparation may in a greater or less degree depend. After having been prepared, they are usually shaped into cylindrical rolls, and wrapped in paper to exclude the air. Plasters should be firm at ordinary temperatures, should spread easily when heated, and after being spread, should remain soft, pliable, and adhesive, without melting at the heat of the human body. When long kept, they are apt to change colour and to become hard and brittle; and as this alteration is most observable upon their surface, it must depend chiefly upon the action of the air, which should therefore be as much as possible excluded. The defect may usually be remedied by melting the plaster with a moderate heat, and adding a sufficient quantity of oil to give it the due consistence.

Plasters are prepared for use by spreading them upon leather, linen, or muslin, according to the particular purposes they are intended to answer. Leather is most convenient when the application is made to the sound skin, linen or muslin when the plaster is used as a dressing to ulcerated or abraded surfaces, or with the view of bringing and retaining together the sides of wounds. The leather usually preferred is white sheep skin. A margin about a quarter or half an inch broad should usually be left uncovered, in order to facilitate the removal of the plaster, and to prevent the clothing in contact with its edges from being soiled. An accurate outline may be obtained by pasting upon the leather a piece of paper, so cut as to leave in the centre a vacant space of the required dimensions, and removing the paper when no longer required. The same object may be accomplished by employing two narrow rulers of sheet tin, graduated in inches, and so shaped that each of them may form two sides of a rectangle. (See the figure, p. 699.) These may be applied in such a manner as to enclose within them any given rectangular space, and may be fixed by weights upon the leather while the plaster is spread. For any other shape, as in the instance of plasters for the breast, pieces of tin may be employed having a vacuity within, corresponding to the required outline. The spreading of the plaster is most conveniently accomplished by means of a peculiar iron instrument employed for the purpose; though a common spatula will answer. This may be heated by means of a spirit lamp. A sufficient portion of the plaster should first be melted by the heated instrument, and having been received on a piece of coarse stiff paper, should, when nearly cool, be transferred to the leather, and applied evenly over its extended surface. By this plan the melted plaster is prevented from penetrating the leather, as it is apt to do when applied too hot. When linen or muslin is used, and the dimensions of the portion to be spread are large, as is often the case with adhesive plaster, the best plan is to pass the cloth "on which the plaster has been laid, through a machine formed of a spatula fixed by screws, at a proper distance from a plate of polished steel." W.

EMPLASTRUM AMMONIACI. *U.S. Lond., Ed., Dub. Ammoniac Plaster.*

Take of Ammoniac *five ounces;* Vinegar *half a pint.* Dissolve the Ammoniac in the Vinegar, and strain; then evaporate the solution in an iron vessel, by means of a water-bath, stirring constantly until it acquires a proper consistence." *U.S.*

The *London* and *Edinburgh Colleges* direct purified ammoniac and distilled vinegar, and omit the straining of the acetic solution. In other respects their processes are the same with ours, except that the Edinburgh College orders five parts of the gum-resin to eight parts of the solvent, instead of five ounces to half a pint. In the *Dublin* process, the ingredients are in the same proportion as in that of the U. S. Pharmacopœia; but pure ammoniac is directed, the vinegar of squill is substituted for common vinegar, the straining is omitted, and the evaporation is conducted without the water-bath.

As ammoniac is not usually kept purified in our shops, the straining of the solution in vinegar is directed as the most convenient method of separating impurities. Dr. Duncan says that the plaster, prepared in iron vessels, as ordered in all the Pharmacopœias, except that of Dublin, "acquires an unpleasant dark colour, from being impregnated with iron; whereas, when prepared in a glass or earthenware vessel, it has a yellowish-white colour, and more pleasant appearance."

Medical Properties. The ammoniac plaster is stimulant, and is applied over scrofulous tumours, and swellings of the joints, to promote their resolution. It often produces a papular eruption, and sometimes occasions considerable inflammation of the skin. Dr. Duncan has described a fatal case of diffuse inflammation following its use in a case of diseased knee joint. W.

EMPLASTRUM AMMONIACI CUM HYDRARGYRO. *Lond., Dub. Plaster of Ammoniac with Mercury.*

"Take of purified Ammoniac *a pound;* Purified Mercury *three ounces;* Sulphurated oil *a fluidrachm.* Rub the Mercury with the sulphurated Oil until the globules disappear; then gradually add the Ammoniac previously melted, and mix the whole together." *Lond.*

"Take of Pure Gum Ammoniac *a pound;* Purified Mercury *three ounces;* Common Turpentine *two drachms.* Rub the Mercury with the Turpentine ntil the globules disappear, then gradually add the Ammoniac previously elted, and with a moderate heat rub them all together till they unite." *Dub.*

Of these processes the latter is preferable, as the unpleasant odour of the lphurated oil is avoided, as well as the action of the sulphur upon the mercury, with which it must form an inactive sulphuret. But it should be recollected that the common turpentine of Great Britain is not the common white turpentine of our shops. The former is a thick liquid, the latter a soft solid. If the white turpentine be employed, it should be rendered sufficiently liquid by the admixture of Venice turpentine. As ammoniac is not fusible by heat, it must be brought to the proper consistence by dissolving it in a small quantity of hot water, straining, and evaporating.

Medical Properties and Uses. This plaster unites with the stimulant power of the ammoniac the specific properties of the mercury, which is sometimes absorbed in sufficient quantity to affect the gums. It is used as a discutient in enlargement of the glands, tumefaction of the joints, nodes and other indolent swellings, especially when dependent on a venereal taint. It is sometimes, also, applied over the region of the liver in chronic hepatitis. W.

EMPLASTRUM AROMATICUM. *Dub.* *Aromatic Plaster.*

"Take of Frankincense [concrete juice of the Pinus Abies] *three ounces;* Yellow Wax *half an ounce;* Cinnamon Bark, in powder, *six drachms;* Oil of Pimento, Oil of Lemons, each, *two drachms.* Melt the Frankincense and Wax together, and strain. When, upon cooling, they begin to thicken, mix in the powdered Cinnamon previously rubbed with the oils, and make a plaster." *Dub.*

As the virtues of this plaster depend chiefly upon volatile ingredients, it cannot be kept long without injury, and should therefore be extemporaneously prepared. It is not intended to be very adhesive, as, in order to maintain the due impression, its application must be frequently renewed. The volatility of the oils requires that it should be spread without being melted or heated more than is absolutely necessary to produce the proper degree of softness. We are therefore recommended to spread it with the fingers.

Medical Properties and Uses. This is an elegant local stimulant, calculated when applied over the region of the stomach to allay nausea and vomiting, to correct flatulence, and to relieve the gastric uneasiness attendant upon dyspepsia. W.

EMPLASTRUM ASSAFŒTIDÆ. *U.S.* EMPLASTRUM ASSAFŒTIDÆ. *Ed.* *Assafetida Plaster.*

"Take of Assafetida, Lead Plaster, each, *a pound* [two parts, *Ed.*]; Galbanum, Yellow Wax, each, *half a pound* [one part, *Ed.*]. Melt together the Plaster and Wax; then add the Assafetida and Galbanum, previously melted and strained, and mix the whole together." *U.S.*

In the first edition of the U.S. Pharmacopœia, the ingredients of this plaster were simply directed to be melted together, and mixed; but experience has shown that they cannot, in this mode, be made to combine properly; and the directions of the Edinburgh College were therefore substituted in the revised edition. Even as the process now stands, it requires some explanation. The galbanum melts sufficiently by the aid of heat to admit of being strained; but this is not the case with the assafetida, which must be prepared by dissolving it in a small quantity of hot water, straining, and evaporating to the consistence of honey; and even the galbanum may be most conveniently treated in the same way. The assafetida may also be brought to the proper consistence by dissolving it in diluted alcohol in the proportion of half a pound to a pint, and evaporating by means of a water-bath.

This plaster may be advantageously applied over the stomach or abdomen, in cases of hysteria attended with flatulence, and to the chest or between the shoulders in hooping cough. W.

EMPLASTRUM BELLADONNÆ. *Dub.* *Plaster of Deadly Nightshade.*

"Take of the Inspissated Juice of the Deadly Nightshade [Extractum Belladonnæ] *an ounce;* Soap Plaster *two ounces.* Make a plaster." *Dub.*

The most convenient method of forming this plaster, is to rub the ingredients together in an earthenware mortar placed in hot water, and then, having removed the mortar from the water-bath, to continue the trituration till the mixture cools. The preparation was introduced into the Dublin Pharmacopœia, as a useful anodyne application in neuralgic and rheumatic pains; and from our own experience we can bear testimony to its beneficial operation in some of these cases. We have seen the constitutional effects of belladonna result from the external use of this plaster. W.

EMPLASTRUM CANTHARIDIS. *Lond.*, *Dub.* EMPLASTRUM CANTHARIDIS VESICATORIÆ. *Ed.* *Plaster of Spanish Flies.* See CERATUM CANTHARIDIS. *U. S.*

EMPLASTRUM CANTHARIDIS VESICATORIÆ COMPOSITUM. *Ed.* *Compound Plaster of Spanish Flies.*

"Take of Venice Turpentine *eighteen parts;* Burgundy Pitch, Spanish Flies, each, *twelve parts;* Yellow Wax *four parts;* Sub-Acetate of Copper *two parts;* White Mustard Seeds, Black Pepper, each *one part.* Having first melted the Pitch and Wax, add the Turpentine; and to these, still hot, add the other ingredients previously reduced to a fine powder and mixed, and stir the whole together till the mixture stiffens on cooling." *Ed.*

This is intended to be a powerful and speedy blistering plaster, and may probably prove beneficial in very urgent cases attended with much torpor of the skin; but great care should be observed not to allow it to remain too long, as unpleasant and tedious ulceration, if not gangrene, might result. To the cases of children it is wholly inapplicable. W.

EMPLASTRUM CERÆ. *Lond.* EMPLASTRUM SIMPLEX. *Ed.* *Wax Plaster.*

"Take of Yellow Wax, Prepared Suet, each, *three pounds;* Yellow Resin *a pound.* Melt them together and strain." *Lond.*

"Take of Yellow Wax *three parts;* Mutton Suet, Pine Resin, each, *two parts.* Melt them together with a gentle heat, and stir the mixture well till it stiffens on cooling." *Ed.*

These plasters were originally intended for dressing blistered surfaces, in order to maintain a moderate discharge, for which purpose they are adapted by the stimulant properties of the resin. But their stiffness and adhesiveness render them unpleasant and of difficult management; and they have been entirely superseded by the resin cerate.

Off. Prep. Emplastrum Cantharidis, *Lond.* W.

EMPLASTRUM CUMINI. *Lond.* *Cumin Plaster.*

"Take of Cumin Seeds, Caraway Seeds, Bay Berries [Lauri Baccæ], each, *three ounces;* Burgundy Pitch *three pounds;* Yellow Wax *three ounces;* Olive Oil, Water, each *a fluidounce and a half.* To the Pitch and Wax melted together, add the dry ingredients previously powdered, the Olive Oil, and the Water; then boil to a proper consistence." *Lond.*

This is a warm, moderately stimulant plaster, occasionally useful in the discussion of indolent tumours, and, when applied over the abdomen, in the relief of flatulence and other symptoms dependent upon a sluggish or debilitated condition of the stomach and bowels. W.

EMPLASTRUM FERRI. *U. S.* EMPLASTRUM OXIDI FERRI RUBRI. *Ed.* EMPLASTRUM THURIS. *Dub.* EMPLASTRUM ROBORANS. *Iron Plaster. Strengthening Plaster.*

"Take of Red Oxide of Iron *eight ounces;* Lead Plaster *two pounds;* Resin *six ounces;* Yellow Wax, Olive Oil, each, *three ounces.* Rub the Red Oxide of Iron with the Oil; then add the other ingredients previously melted together by means of a water-bath, and mix the whole." *U.S.*

The process of the *Edinburgh College* corresponds with the above in the proportions of the ingredients, and the general mode of proceeding.

The *Dublin College* directs that two pounds of litharge plaster (Emplastrum Plumbi) be melted with half a pound of frankincense (concrete juice of the *Pinus Abies*); that three ounces of the red oxide of iron be afterwards added; and the whole stirred together, so as to form a plaster.

This preparation has enjoyed some popular celebrity, under the impression that it strengthens the parts to which it is applied; whence it has derived the name of strengthening plaster. It is used in those conditions of the loins, larger muscles, and joints, which, though usually ascribed to debility, are in fact most frequently dependent on rheumatic or other chronic inflammatory affections, and, if relieved by the plaster, are so in consequence of the gentle excitation which it produces in the vessels of the skin. It may also, in some instances, give relief by affording mechanical support; but neither in this, nor in any other respect, can it be deemed very efficient. Prepared according to the U. S. and Edinburgh process, it is deficient in the qualities which characterize a good plaster, and among others that of adhesiveness. We should prefer the process of the Dublin Pharmacopœia, Burgundy pitch being substituted for frankincense. W.

EMPLASTRUM GALBANI. *Dub.* *Galbanum Plaster.*

"Take of Litharge Plaster [Emplastrum Plumbi] *two pounds*; Galbanum *half a pound*; Yellow Wax, sliced, *four ounces.* Add the Litharge Plaster and Wax to the Galbanum previously melted; then melt the whole together with a moderate heat, and strain." *Dub.*

This is essentially the same in properties as the following, though somewhat less stimulating. W.

EMPLASTRUM GALBANI COMPOSITUM. *U. S.* *Lond.* *Compound Galbanum Plaster.*

"Take of Galbanum *eight ounces;* Lead Plaster *three pounds;* Turpentine *ten drachms;* Burgundy Pitch, in powder, *three ounces.* Melt together the Galbanum and Turpentine; then add first the Burgundy Pitch, afterwards the Lead Plaster previously melted over a slow fire, and mix the whole together." *U.S.*

The *London* process differs only in directing the galbanum previously purified, (see *Gummi-resinæ*,) instead of the gum-resin in its ordinary state, and the concrete juice or unprepared resin of the Pinus Abies, instead of Burgundy pitch or the prepared resin.

It is a defect of the process of the United States Pharmacopœia, not to have ordered the galbanum purified, as it often contains foreign matters which must injure the plaster. It may be freed from these by melting it with a little water, straining, and evaporating to the due consistence. There is no necessity for employing the Burgundy pitch in powder.

This plaster is an excellent local stimulant in chronic scrofulous enlargements of the glands and joints. We have employed it with apparent advantage in some obstinate cases of this kind, which after having resisted general and local depletion, blistering, and other measures, have yielded under its use. As a discutient it is also employed in the induration which sometimes remains after the discharge of abscesses. It is said to have been useful in rickets when applied over the whole lumbar region, and has been recommended in chronic gouty or rheumatic articular affections. It should not be employed in the discussion of tumours in which any considerable inflammatory action exists.
W.

EMPLASTRUM GUMMOSUM. *Ed.* *Gum Plaster.*

"Take of Plaster of Semivitrified Oxide of Lead [Emplastrum Plumbi] *eight parts;* Gum Ammoniac, Galbanum, Yellow Wax, each, *one part.* To the melted Plaster and Wax, add the Gum-resins, previously melted and strained, and mix the whole thoroughly." *Ed.*

The addition of ammoniac adds little to the virtues of this plaster, which closely resembles the compound galbanum plaster in its effects. The galbanum and ammoniac are best prepared by dissolving them in a small quantity of hot water, straining the solution, and evaporating it to the proper consistence for mixing with the other ingredients.
W.

EMPLASTRUM HYDRARGYRI. *U.S., Lond., Ed.* *Mercurial Plaster.*

"Take of Mercury *six ounces;* Olive Oil, Resin, each, *two ounces;* Lead Plaster *a pound.* Melt the Oil and Resin together, and when they have become cool, rub the Mercury with them till the globules disappear; then gradually add the Lead Plaster, previously melted, and mix the whole together." *U.S.*

By the process of the *London College* three ounces of purified mercury are extinguished by trituration with a fluidrachm of sulphurated oil; a pound of lead plaster, previously melted, is then gradually added, and the whole mixed together. The *Edinburgh* process corresponds precisely, except in phraseology, with that of the United States Pharmacopœia.

The sulphurated oil employed by the London College is intended to facilitate the extinguishment of the mercury; but as it operates by the union of the sulphur with the metal forming an inefficient sulphuret, it impairs the virtues of the plaster at least as much as it assists in its preparation. The melted resin and oil of the United States and Edinburgh process are decidedly preferable.

This plaster is employed to produce the local effects of mercury upon venereal buboes, nodes, and other chronic tumefactions of the bones or soft parts, dependent on a syphilitic taint. In these cases it sometimes acts as a powerful discutient. It is frequently also applied to the side in chronic hepatitis or splenitis. In habits peculiarly susceptible to the mercurial influence, it occasionally affects the gums.
W.

EMPLASTRUM OPII. *Lond., Ed., Dub.* *Opium Plaster.*

"Take of Opium, in powder, *half an ounce;* Burgundy Pitch *three ounces;* Plaster of Semivitrified Oxide of Lead [Emplast. Plumbi] *a pound.* Add the Opium and Pitch to the Plaster, previously melted, and mix them horoughly." *Ed., Dub.*

"Take of Hard Opium, in powder, *half an ounce;* Resin of the Spruce ir [unprepared concrete juice of the *Pinus Abies*], in powder, *three ounces;* Lead Plaster *a pound;* Water *half a pint.* To the melted Plaster add the

Resin, Opium, and Water; and boil down with a slow fire until the ingredients unite into the consistence of a plaster." *Lond.*

The opium plaster is thought to relieve rheumatic and other pains in the parts to which it is applied. W.

EMPLASTRUM PICIS COMPOSITUM. *Lond.* *Compound Pitch Plaster.*

"Take of Burgundy Pitch *two pounds;* Resin of the Spruce-fir [unprepared concrete juice of the *Pinus Abies*] *a pound;* Yellow Resin, Yellow Wax, each, *four ounces;* Expressed Oil of Nutmegs *an ounce;* Olive Oil, Water, each, *two fluidounces.* To the Pitch, Resin, and Wax, melted together, add first the Resin of the Spruce-fir, then the Oil of Nutmegs, the Olive Oil, and the Water. Lastly, mix the whole, and boil down to the proper consistence." *Lond.*

The driest white turpentine may be substituted for the resin of the spruce-fir, which is not always to be obtained in this country.

This is a rubefacient plaster applicable to catarrhal and other pectoral affections, chronic inflammation of the liver, and rheumatic pains in the joints and muscles. It often keeps up a serous discharge, which requires that it should be frequently renewed. The irritation which it sometimes excites is so great as to render its removal necessary. W.

EMPLASTRUM PICIS CUM CANTHARIDE. *U.S.* EMPLASTRUM CALEFACIENS. *Dub.* *Plaster of Pitch with Spanish Flies. Warming Plaster.*

"Take of Burgundy Pitch *three pounds and a half;* Cerate of Spanish Flies *half a pound.* Melt them together by means of a water-bath, and stir them constantly till they thicken upon cooling." *U.S.*

The *Dublin College* employs the same proportions.

This plaster is an excellent rubefacient, more active than Burgundy pitch, yet in general not sufficiently so to produce vesication. Still, however, in consequence of a peculiar susceptibility of the skin in some individuals, it occasionally blisters; and it has been recommended to diminish the proportion of the flies. But, while such a reduction would render the plaster insufficiently active in most cases; it would not entirely obviate the objection, as the smallest proportion of flies would vesicate in certain persons, and even the Burgundy pitch alone sometimes produces the same effect. In whatever mode, therefore, this plaster may be prepared, it cannot always answerthe expectations which may be entertained; and the only plan, when the skin of any individual has been found to be very susceptible, is to accommodate the proportions to the particular circumstances of the case. Much, however, may be accomplished by proper care in the preparation of the plaster, towards obviating its tendency to blister. If the flies of the *Ceratum Cantharidis* should have been coarsely pulverized, the larger particles, coming in contact with the skin, will exert upon the particular part to which they are applied their full vesicatory effect, while, if reduced to a very fine powder, they would be more thoroughly enveloped in the other ingredients, and thus have their strength very much diluted. Now the former condition of the cerate when prepared for ordinary use is not objectionable, as the design in this case is to produce a blister. Hence particular care is neither necessary nor observed in powdering the flies under these circumstances. But as an ingredient of the warming plaster, the cerate should contain the cantharides as minutely divided as possible, and if that usually kept is not in the proper state, a portion should be prepared for this particular purpose.

The warming plaster is employed in chronic rheumatism, and various chronic internal diseases attended with inflammation or an inflammatory tendency, such as chronic catarrh, asthma, pertussis, phthisis, hepatitis, and the sequelæ of pleurisy and pneumonia. W.

EMPLASTRUM PLUMBI. *U.S. Lond.* EMPLASTRUM OXIDI PLUMBI SEMIVITREI. *Ed.* EMPLASTRUM LITHARGYRI. *Dub.* *Lead Plaster. Litharge Plaster.*

"Take of Semivitrified Oxide of Lead, in very fine powder, *five pounds;* Olive oil *a gallon;* Water *two pints.* Boil them together over a gentle fire, stirring constantly, until the Oil and Oxide of Lead unite into a Plaster. It will be proper to add a little boiling water, if that employed at the commencement be nearly all consumed before the end of the process." *U.S. Lond.*

The *Edinburgh College* orders one part of the semivitrified oxide of lead, two parts of olive oil, and a sufficient quantity of water. The *Dublin* process does not differ materially from that of the London and U.S. Pharmacopœias.

The importance of this plaster, as the basis of most of the others, requires that we should enter somewhat in detail into an account of the principles and manner of its preparation.

It was formerly thought that the oil and oxide of lead entered into direct union, and that the presence of water was necessary only to regulate the temperature, and prevent the materials from being decomposed by heat. The discovery, however, was afterwards made, that this liquid was essential to the process; and that the oil and oxide alone, though maintained at a temperature of 220°, would not combine, while the addition of water, under these circumstances, would produce their immediate union. It was now supposed that the oil was capable of combining only with the hydrated oxide of lead, and that the use of the water was to bring the oxide into this state; and in support of this opinion, the fact was advanced, that the hydrated oxide of lead and oil would form a plaster when heated together without any free water. (See *N. Am. Med. and Surg. Journ.* vol. i. p. 469.) But since the general reception of Chevreul's views in relation to oils and their combination with alkalies and other metallic oxides, the former opinions have been abandoned; and it is now admitted that the preparation of the lead plaster affords a genuine example of saponification, as explained by that chemist. The elements of the oil undergo a new arrangement, one portion of them, though comparatively small, uniting with a portion of the water to form a sweetish substance called *glycerine*, and the remainder, constituting more than ninety parts in the hundred, combining among themselves to produce two acid bodies, the *oleic* and *margaric acids*, to which, when animal fat is employed, instead of olive oil, a third is added, namely the *stearic.*[*] The plaster is formed by a union of these acids with the oxide, and, prepared according to the directions of the Pharmacopœias, is in fact an oleo-margarate of lead. The glycerine remains dissolved in the water or mechanically mixed with the plaster. That such is the correct view of the nature of this compound, is evinced by the fact, that if the oxide of lead be separated from the plaster by digestion at a moderate heat in very dilute nitric acid, the fatty matter which remains will unite with litharge with the greatest facility, without the intervention of water.

---

[*] Berzelius thinks it probable that the margaric acid is a compound of the oleic and stearic, and that in fact only two acids are generated.

Other oleaginous substances and other metallic oxides are susceptible of the same combination, and some of them form compounds having the consistence of a plaster; but, according to *M. Henry* of Paris, who has fully investigated the subject, no oily matter except animal fat can properly be substituted for olive oil, and no metallic oxide, not even one of the other oxides of lead, for litharge. He ascertained, moreover, that the English litharge is preferable for the formation of the lead plaster to that obtained from Germany. Red lead, which is a deutoxide of that metal, forms a plaster with oil or fat, without the addition of water; but it is always of a deep brown colour, as if burnt. It is supposed, in this case, that the oil is acidified by the agency of the oxygen, which the deutoxide affords when heated.

Preparation. The vessel in which the lead plaster is prepared, should be of such a size that the materials will not occupy more than two-thirds of its capacity. The oil should be first introduced, and the litharge then sprinkled in by means of a sieve, the mixture being constantly stirred with a spatula. The particles of the oxide are thus prevented from coalescing in small masses which the oil would not easily penetrate, and which would therefore delay the process. Though water exerts an important chemical agency in the changes which occur, it is also useful by preventing too high a temperature, which would decompose the oil and cause the reduction of the metal. The waste must therefore be supplied by fresh additions as directed in the process; and the water added for this purpose should be previously heated, as otherwise it would not only delay the operation, but by producing explosion might endanger the operator. During the continuance of the boiling, the materials should be constantly stirred, and the spatula should be repeatedly passed along the bottom of the vessel, from side to side, so as to prevent any of the oxide, which is disposed by its greater density to sink to the bottom, from remaining in that situation. The materials swell up considerably in consequence partly of the vaporization of the water, partly of the escape of carbonic acid gas, which is liberated by the oily acids from some carbonate of lead usually contained in the litharge. (*Chevallier.*) The process should not be continued longer than is sufficient to produce complete union of the ingredients, and this may be known by the colour and consistence of the mass. The colour of the litharge gradually becomes paler, and at length almost white when the plaster is fully formed. The consistence increases with the progress of the boiling, and is sufficiently thick, when a portion of the plaster taken out and allowed to cool upon the end of a spatula, or thrown into cold water, becomes solid, without adhering in this state to the fingers. The portion thus solidified should not present, when broken, any red points, which would indicate the presence of a portion of uncombined litharge. When the plaster is formed, it should be removed from the fire, and after a short time cold water should be poured upon it; portions should then be detached from the mass and having been well kneaded under water, in order to separate the viscid liquid contained in the interior, should be formed into cylindrical rolls, and wrapped in paper.*

Medical Properties and Uses. This plaster, which has long been known under the name of *diachylon*, is used as an application to excoriated surfaces, and to slight wounds, which it serves to protect from the action of the air. It may also be beneficial by the sedative influence of the lead which enters into its composition. But its chief use is in the preparation of other plasters.

Off. Prep. Emplastrum Assafœtidæ, *U.S.*, *Ed.*; Emp. Ferri, *U.S. Ed.*;

---

* For many of these remarks on the lead plaster, we are indebted to Chevallier's *Manuel du Pharmacien.*

Dub.; Emp. Galbani. *Dub.;* Emp. Galbani Comp. *U. S., Lond.;* Emp. Gummosum, *Ed.;* Emp. Hydrargyri, *U. S., Lond., Ed.;* Emp. Opii, *Lond., Ed., Dub.;* Emp. Plumbi Carbonatis, *U. S.;* Emp. Resinæ, *U. S., Lond., Ed., Dub.;* Emp. Saponis, *Lond., Ed., Dub.;* Emp. Saponis Comp., *Dub.* W.

EMPLASTRUM PLUMBI CARBONATIS. *U. S.* *Plaster of Carbonate of Lead.*

"Take of Carbonate of Lead *a pound;* Olive Oil *two pints;* Yellow Wax *four ounces;* Lead Plaster *a pound and a half;* Florentine Orris, in powder, *nine ounces.* Boil together the Oil and Carbonate of Lead, adding a little water, and constantly stirring, till they are thoroughly incorporated; then add the Wax and Plaster, and when these are melted sprinkle in the Orris, and mix the whole together." *U. S.*

In the first edition of the U.S. Pharmacopœia, the oil and carbonate of lead were directed to be boiled together by means of a water-bath, till they were incorporated; but they cannot be made to unite in this manner, and the present directions were very properly substituted in the last edition. According to the process as it now stands, a good plaster may be prepared, rather too soft, perhaps, at first, but soon acquiring the proper consistence.

The plaster of carbonate of lead was introduced into our Pharmacopœia as a substitute for *Mahy's plaster*, so much employed in some parts of the United States. It is an excellent application to surfaces inflamed or excoriated by friction; and may be resorted to with great advantage in those troublesome cases of cutaneous irritation, and even ulceration, occurring upon the back and hips during long continued confinement to one position.

Off. Prep. Ceratum Plumbi Carbonatis, *U. S.* W.

EMPLASTRUM RESINÆ *U. S., Lond.* EMPLASTRUM RESINOSUM. *Ed.* EMPLASTRUM LITHARGYRI CUM RESINA. *Dub.* EMPLASTRUM ADHÆSIVUM. *Resin Plaster. Adhesive Plaster.*

"Take of Resin, in powder, *half a pound;* Lead Plaster *three pounds.* To the Lead Plaster melted over a gentle fire add the Resin, and mix them." *U. S., Lond.*

The *Edinburgh College* orders five parts of the lead plaster and one of resin; the *Dublin,* three pounds and a half of the former, and half a pound of the latter.

This preparation differs from the lead plaster in being more adhesive and somewhat more stimulating. It is the common adhesive plaster of the shops, and is much employed for retaining the sides of wounds in contact, and for dressing ulcers according to the method of Baynton, by which the edges are drawn towards each other, and a firm support is given to the granulations. It is usually spread for these purposes upon muslin; and the spreading is best accomplished, on a large scale, by means of a machine, as described in the general observations upon plasters. It is kept in the shops ready spread; but as the plaster becomes less adhesive by long exposure to the air, the supply should be frequently renewed. When the skin is very delicate, it occasionally excites some irritation; and under these circumstances a plaster may be substituted, containing a smaller proportion of resin. That originally employed by Baynton contained only six drachms of resin to the pound of lead plaster.

In order to render the plaster more adhesive, and less brittle in cold weather, it is customary with many apothecaries to employ a considerable proportion of Burgundy pitch or turpentine in its preparation; but these additions are objectionable, as they greatly increase the liability of the plaster to irritate the skin, and thus materially interfere with the purposes for which the preparation was chiefly intended. If the remarks of Dr. Duncan on the compound soap plaster of the Dublin Pharmacopœia may be relied on, this might be advantageously substituted for the resin plaster in winter. (See *Emplastrum Saponis Compositum.*) W.

EMPLASTRUM SAPONIS. *Lond., Dub.* EMPLASTRUM SAPONACEUM. *Ed.* *Soap Plaster.*

"Take of Hard Soap, sliced, *half a pound;* Lead Plaster *three pounds.* Mix the Soap with the melted Plaster; then boil them down to the proper consistence." *Lond., Dub.*

"Take of Plaster of Semivitrified Oxide of Lead [Emplastrum Plumbi] *four parts;* Gum Plaster *two parts;* Hard Soap, sliced, *one part.* To the Plasters melted together add the Soap; then boil a little, so as to form a plaster." *Ed.*

In relation to the soap plaster of the London and Dublin Colleges, Dr. Montgomery, in his Observations upon the Dublin Pharmacopœia, makes the following remark. "I am informed by Mr. Scanlan, who prepares this plaster in large quantities, that the quantity of soap is twice too great, the plaster being, when prepared by this formula, quite pulverizable, and falling into crumbs." After the addition of the soap to the melted lead plaster, it is only necessary to continue the heat for a short time, till the soap is incorporated. Boiling is not necessary.

Soap plaster is considered discutient, and is sometimes used as an application to tumours.

Off. Prep. Emp. Belladonnæ, *Dub.;* Emp. Saponis Comp., *Dub.* W.

EMPLASTRUM SAPONIS COMPOSITUM vel ADHÆRENS. *Dub.* *Compound Soap Plaster, or Adhesive Plaster.*

"Take of Soap Plaster *two ounces;* Litharge Plaster with Resin [Emplast. Resinæ] *three ounces.* Make a plaster, which is to be melted and spread on linen." *Dub.*

Dr. Duncan, in his Dispensatory, makes the following observations in relation to this preparation. "The common resinous plaster is in cold weather too brittle, and apt to crack off from the linen on which it is spread; but by combining it in due proportion with soap plaster, it acquires greater pliability, without losing its adhesive property. In fact, this is the plaster commonly spread by a machine on webs of linen, and sold under the name of adhesive plaster." W.

ENEMATA. *Dub.*

Clysters.

These can scarcely be considered proper objects for officinal direction; but having been introduced into the Dublin Pharmacopœia, the plan of this work requires that we should notice them. They are substances in the liquid form, intended to be thrown up the rectum, with the view either of evacuating the bowels, or of producing the peculiar impression of a remedy upon the lower portion of the alimentary canal and neighbouring organs, or of acting on the system generally through the medium of the surface to which they are applied. They are usually employed to assist the action of remedies taken by the mouth, or to supply their place when the stomach rejects them, or is insensible to their impression. Sometimes they are preferably used, when the seat of the disorder is in the rectum or its vicinity.

As a general rule, three times as much of any remedy is required to produce a given impression by enema, as when taken into the stomach; but this rule should be acted on with caution, as the relative susceptibilities of the stomach and rectum are not the same in all individuals; and with regard to all very active remedies, the best plan is to administer less than the stated proportion. Attention should also be paid to the fact, that, by the frequent use of a medicine, the susceptibility of the stomach may be in some measure exhausted, without a proportionate diminution of that of the rectum.

When the object is to evacuate the bowels, the quantity of liquid administered should be considerable. For an adult from ten fluidounces to a pint, for a child of eight or ten years half that quantity, for an infant within the year from one to three fluidounces, are about the proper proportions. Much larger quantities of mild liquids may sometimes be given with safety and advantage; as the bowels will occasionally feel the stimulus of distention, when they are insensible to impressions of an irritating character.

When the design is to produce the peculiar impression of the remedy upon the neighbouring parts or the system, it is usually desirable that the enema should be retained; and the liquid vehicle should therefore be bland, and as small in quantity as is compatible with convenient administration. A solution of starch, flaxseed tea, or other mucilaginous fluid should be selected, and the quantity given should seldom exceed two or three fluidounces.

In every case, the patient should be instructed to resist any immediate disposition to discharge the injected fluid; and his efforts to retain it should be assisted, if necessary, by pressure with a warm folded towel upon the fundament.

The best instrument for administering enemata is an accurate metallic syringe. W.

ENEMA CATHARTICUM. *Dub.* *Cathartic Clyster.*

"Take of Manna *an ounce.* Dissolve it in *ten fluidounces* of Compound Decoction of Chamomile, and add of Olive Oil *an ounce*, Sulphate of Magnesia *half an ounce.*" *Dub.*

The laxative enema most commonly employed in this country, and in all respects equal to the above, consists of a tablespoonful of common salt, two tablespoonfuls of lard or sweet oil, the same quantity of molasses, and a pint of warm water. It has the advantage of consisting of materials which are always at hand in families. W.

ENEMA FŒTIDUM. *Dub*, *Fetid Clyster.*

"This is made by adding to the Cathartic Clyster two drachms of Tincture of Assafetida." *Dub.*

It is carminative and antispasmodic, as well as laxative; but when the peculiar influence of assafetida is desired by way of enema, we prefer the gum-resin itself rubbed up with hot water, in the proportion of one or two drachms to half a pint, of which the whole or a part may be given according to circumstances. W.

ENEMA OPII. *Dub.* *Clyster of Opium.*

"Take of Tincture of Opium *a drachm;* Warm Water *six ounces.* Mix them." *Dub.*

This contains too much both of the tincture and the vehicle. It must have happened to every one in the habit of prescribing opium in this way, to have seen a much greater effect produced by a certain amount of laudanum injected into the rectum than by one-third of the quantity swallowed.

The fluidrachm—the drachm of the Dublin formula—contains at least one hundred drops of laudanum of the ordinary size, aud not less than one hundred and twenty as they are often formed. From twenty to twenty-five drops are usually considered as a medium dose; so that the Dublin College orders five times as much by the rectum as is given by the mouth. Sixty drops, equivalent to about thirty minims, are abundantly sufficient. As the object is that the enema should remain in the rectum, the smaller the quantity of the vehicle the better; and a mucilaginous fluid is preferable to water, as it involves the tincture and prevents the irritation of the alcohol before the opium begins to take effect. The ordinary anodyne enema employed in this country consists of about sixty drops of laudanum and one or two fluidounces of flaxseed tea or solution of starch.

It is an admirable remedy in obstinate vomiting, strangury from blisters, painful affections of the kidneys, bladder, and uterus, and in the tenesmus of dysentery. It may also frequently be employed to produce the effects of opium upon the system; when circumstances prevent the administration of this medicine by the mouth. W.

ENEMA TEREBINTHINÆ. *Dub.* *Clyster of Turpentine.*

"Take of Common Turpentine *half an ounce;* the Yolk of one Egg. Rub them together, and add gradually *ten ounces* of Water of a temperature not exceeding 100°." *Dub.*

As the common turpentine alluded to in the formula is not usually kept in the shops of this country, we almost always employ the oil of turpentine, which is even more efficacious, and in no respect inferior for the purpose. (See *Oleum Terebinthinæ.*) W.

EXTRACTA.

Extracts.

Extracts, as the term is employed in the U.S. and London Pharmacopœias, are solid substances, resulting from the evaporation of the solutions of vegetable principles, obtained either by exposing the vegetable to the action of a solvent, or by expressing its juice in the recent state. The Edinburgh and Dublin Colleges make a distinction between those prepared from the infusions, decoctions, or tinctures, and those from the expressed juices of plants, calling the former *Extracta*, the latter *Succi Spissati*. But there is no such essential difference between these two sets of preparations, as to require that they should be separately classed; and something is gained in the simplicity of nomenclature, as well as of arrangement, which results from their union. We shall consider them under the same head, taking care, however, to detail distinctly whatever is peculiar in the mode of preparing each.

The composition of extracts varies with the nature of the vegetable, the character of the solvent, and the mode of preparation. The object is generally to obtain as much of the active principles of the plant, with as little of its inert matter as possible; though sometimes it may be desirable to separate the active ingredients from each other, when their effects upon the system are materially different; and this may be accomplished by employing a menstruum which, while it dissolves one, leaves the other untouched. The proximate principles most commonly present in extracts are gum, sugar, starch, tannin, extractive, colouring matter, salts, and the peculiar principles of plants; to which, when a spirituous solvent is employed, may usually be added resinous substances, fatty matter, and frequently more or less essential oil—gum and starch being excluded when the menstruum is pure alcohol. Of these substances, as well as of others which, being soluble, are sometimes necessarily present in extracts, we have taken occasion to treat under various heads in the Materia Medica. There is one, however, which, from its supposed almost uniform presence in this class of preparations, and from the influence it is thought to exert upon their character, deserves particular consideration in this place;—we allude to *extractive*, or, as it is sometimes called, *extractive matter.*

It has long been observed, that in most vegetables there is a substance, soluble both in water and alcohol, which, in the preparation of extracts, undergoes some chemical change during the process of evaporation, imparting to the liquid, even if originally limpid, first a greenish, then a yellowish-brown, and ultimately a deep brown colour, and becoming itself insoluble. This substance, originally called *saponaceous matter* by Scheele, afterwards received the more expressive name of *extractive*, derived from its very frequent presence in extracts. Its existence as a distinct principle is denied, or at least doubted by some chemists, who consider the phenomena supposed to result from its influence, as depending upon the mutual reaction of other principles; and in relation to Peruvian bark, it appears to have been proved, that the insoluble matter which forms during its decoction in water, is a compound of starch and tannin. A similar compound must also be formed in other cases when these two principles co-exist; but they are not always present in the same vegetable, nor can all the changes which have been attributed to the extractive, be accounted for by their union, even when they are present; so that till further light is shed on the subject, it is best to admit the existence of a distinct substance, which, though not the same in all plants, possesses sufficient identity of character to be entitled, like sugar, tannin, &c. to a distinctive name. The most interesting property of extractive is its disposition to pass, by the influence of atmospheric air at a high temperature, into an insoluble substance. If a vegetable infusion or decoction be evaporated in the open air to the consistence of an extract, then diluted, filtered, and again evaporated, and the process repeated so long as any insoluble matter is formed, the whole of the extractive will be separated from the liquid, which will then contain only the gum, sugar, saline matters, &c., which may have existed in the plant. If chlorine be passed through an infusion or decoction, a similar precipitate is formed with much greater rapidity. The change is usually ascribed to the absorption of oxygen by the extractive, which has therefore been called, in its altered condition, oxidized extractive; but De Saussure ascertained, that though oxygen is absorbed during the process, an equal measure of carbonic acid gas is given out, and the oxygen and hydrogen of the extractive unite to form water in such a manner as to leave the principle richer in carbon than it was originally. The name of oxidized extractive is therefore obviously incorrect, and Berzelius proposes to substitute for it that of *apothême*, synonymous with deposite. According to Berzelius, *apothême* is not completely insoluble in water, but imparts a slight colour to that liquid when cold, and is rather more soluble in boiling water, which becomes turbid upon cooling. It is still more soluble in alcohol, and is freely dissolved by solutions of the alkalies and alkaline carbonates, from which it is precipitated by acids. It has a great tendency, when precipitated from solutions, to unite with other principles, and to carry them along with it, thus acquiring properties somewhat different, according to the source from which it is obtained. In this way, also, even when the extractive of a plant is itself medicinally inert, its conversion into *apothême* may be injurious, by causing a precipitation of a portion of the active principle; and in practical pharmaceutic operations, this change should always, if possible, be avoided. With these preliminary views, we shall proceed to the consideration of the practical rules necessary to be observed in the preparation of extracts. We shall treat of the subject under the several heads, 1. of the extraction of the soluble principles from the plant; 2. of the method of conducting the evaporation; 3. of the proper condition of extracts, the changes they are liable to undergo, and the best methods of preserving them; and 4. of the general directions of the several Pharmacopœias in relation to them.

1. *Extraction of the Soluble Principles.*

There are two distinct modes of obtaining, in a liquid state, the principles which we wish to extract; 1. by expression; 2. by the agency of a solvent.

1. *By expression.* This method is applicable only to recent vegetables. All plants cannot be advantageously treated in this way, as many have too little juice to afford an appreciable quantity upon pressure, and of those which are succulent, a considerable proportion do not yield all their active principles with their juice. Succulent fruits, and various acrid and narcotic plants, are proper subjects of this treatment. With the exception of the fruit of the *Sambucus nigra*, the inspissated juice of which is directed by the Edinburgh and Dublin Colleges, all the vegetables from which officinal extracts are prepared in this way belong to the class of narcotics. The plants should be operated upon, if possible, immediately after their collection. Mr. Battley of London recommends that if not entirely fresh, they should be revived by the immersion of the stalks in water for twelve or eighteen hours, and those only used which recover their freshness by this management. They should then be cut into pieces, and bruised in a stone mortar till brought to a pulpy consistence. When the plant is not very succulent, it is necessary to add a little water during this part of the process, in order to dilute the juice. After sufficient contusion, the pulp is introduced into a linen or canvass bag, and the liquid parts expressed. The juice thus obtained is opaque and usually green, in consequence of the presence of green wax or chlorophylle, and of a portion of the undissolved vegetable fibre in a state of minute division. By heating the juice to about 160°, the albumen contained in it coagulates, and involving the chlorophylle and vegetable fibre, forms a greenish precipitate. If the liquid be now filtered, it becomes limpid and nearly colourless, and is prepared for evaporation. The clarification, however, is not absolutely necessary, and is generally neglected. Sometimes the precipitate carries with it a considerable portion of the active principle; in which case it should be subsequently incorporated with the juice, when reduced by evaporation to the consistence of a syrup.

2. *By solution.* The active principles of dried vegetables can be extracted only by means of a liquid solvent. The menstruum employed is either water or alcohol, or a mixture of the two. Water, on account of its cheapness, is always preferred, when circumstances do not strongly call for the use of alcohol. It has the advantage, moreover, that its operation may be assisted, if necessary, by a higher degree of heat than the latter. Pump water is often unfit for the purpose, in consequence of the quantity of its saline matter, which, in some instances, may exert an unfavourable influence on the active principle, and must always be left in the extract. Rain or river or distilled water should be preferred. Alcohol is employed when the principles to be extracted are insoluble, or but slightly soluble in water, as in the case of the resins; when it is desirable to avoid in the extract inert

substances, such as gum and starch, which are dissolved by water and not by alcohol; when the heat required to evaporate the aqueous solution would dissipate or decompose the active ingredients of the plant, as the volatile oils and the active principle of sarsaparilla; and finally, when the nature of the substance to be exhausted requires so long a maceration in water as to endanger spontaneous decomposition. The watery solution requires to be soon evaporated, as this fluid rather promotes than counteracts chemical changes; while an alcoholic tincture may be preserved unaltered for an indefinite period. An addition of alcohol to water is sufficient to answer some of the purposes for which the former is preferable; and the employment of both fluids is essential, when the virtues of the plant reside in two or more principles, all of which are not soluble in either of these menstrua. In this case it is usually better to submit the vegetable to the action of the two fluids successively, than to both united. Extracts obtained by the agency of water, are called *watery* or *aqueous extracts*, those by means of alcohol rectified or diluted, *alcoholic* or *spirituous extracts*.

The method of preparing the solution is by no means a matter of indifference. The vegetable should be thoroughly bruised, or reduced to the state of coarse powder, so as to allow the access of the solvent to all its parts, and yet not so finely pulverized as to prevent a ready precipitation of the undissolved and inactive portion. When water is employed, it is usual to boil the medicine for a considerable length of time, and if the first portion of liquid does not completely exhaust it, to repeat the operation with successive portions, till the whole of the active matter is extracted. This may be known by the sensible properties of the liquid, and by its influence upon reagents. But the boiling temperature produces decomposition of many vegetable principles, or at least so modifies them as to render them inert; and the extracts prepared by decoction are usually less efficient than those prepared with a less degree of heat. From numerous experiments upon extracts, Orfila concluded that their virtues were less in proportion to the heat used in their preparation. It is recommended, therefore, to substitute for decoction, the process of maceration, digestion, or hot infusion; in the first of which the liquid acts without heat, in the second is assisted by a moderately increased temperature sustained for a considerable time, and in the third is poured boiling hot upon the vegetable matter, and allowed to stand for a short period in a covered vessel. When the active principles are readily soluble in cold water, *maceration* is preferable to any other mode, as the starch which is inert, is thus left behind; but in many instances the preparation would spoil before the extraction would be completed. By *digestion*, though the solvent power of water is moderately increased, the advantage is more than counterbalanced by the increased disposition to spontaneous decomposition. *Infusion*, therefore, is generally preferred when decoction is not resorted to. A convenient mode of performing this process, is to introduce the solid material into a vessel with an opening near the bottom temporarily closed, or into a funnel with its mouth loosely stopped, then to pour on the boiling water, and having allowed it to remain a sufficient length of time, to draw it off through the opening. This operation may be repeated till the water comes away without any obvious impregnation. It is, however, always desirable to obtain the solution in the first place as concentrated as possible, so as to prevent the necessity of long continued evaporation, which has a tendency to injure the extract. It is better, therefore, to incur the risk, both where decoction and infusion are employed, of leaving a portion of the active matter behind, than to obtain a very weak solution. When successive portions of water are employed, those which are least impregnated should be brought by evaporation to the strength of that first obtained before being mixed with it, as the latter thus escapes exposure to unnecessary heat.

When alcohol is employed as a menstruum, the vegetable should be macerated in it for one or two weeks, and care should be taken that the tincture be as nearly saturated as possible. The extraction may be hastened by substituting digestion for maceration, as the moderate heat employed, while it facilitates the action of the alcohol, has in this case no effect in promoting decomposition, and the influence of the atmospheric air may be excluded by performing the process in close vessels. When alcohol and water are both used, it is best, as a general rule, to exhaust the vegetable with each separately, as the two menstrua require different modes of treatment.

By whatever process the extraction is effected, it requires the assistance of occasional agitation; and when the vegetable matter is very porous, and absorbs large quantities of the solvent, expression must be resorted to.

2. *Mode of conducting the Evaporation.*

In evaporating the solutions obtained in the modes above described, attention should always be paid to the fact, that the extractive matter is constantly becoming insoluble at high temperatures with the access of air, and that other chemical changes are going on, sometimes not less injurious than this, while the volatile principles are expelled with the vapour. The operator should, therefore, observe two rules; 1. to conduct the evaporation at as low a temperature as is consistent with other objects; 2. to exclude as much as possible the atmospheric air, and when this cannot be accomplished, to expose the liquid the shortest possible time to its action. According to Berzelius, the injurious influence of the atmospheric air is much greater at the boiling point of water that at a less heat, even allowing for the longer exposure in the latter case; and, therefore, a slow evaporation at a moderate heat is preferable to the more rapid effects of ebullition. Bearing these principles in mind, we shall proceed to examine the different modes in practice. First, however, it is proper to observe, that decoctions generally let fall upon cooling a portion of insoluble matter; and it is a question whether this should be rejected, or retained so as to form a part of the extract. Though it is undoubtedly in many instances inert, as in that of the insoluble tannate of starch formed during the decoction of certain vegetable substances, yet, as it frequently also contains a portion of the active principle which a boiling saturated solution necessarily deposites on cooling, and as it is difficult to decide with certainty when it is active and when otherwise, the safest plan, as a general rule, is to allow it to remain.

The method of evaporation usually resorted to in the case of the aqueous solutions is rapid boiling over a fire. The more quickly the process is conducted, the better, provided the liquid is to be brought to the boiling point; for the temperature cannot exceed this, and the length of exposure is diminished. But even where this method is employed, it should not be continued till the completion of the evaporation; for when most of the water has escaped, the temperature can no longer be kept down to the boiling point, and the extract is burnt. The caution, therefore, should always be observed of removing the preparation from the fire, before it has attained the consistence of thick syrup, and completing the evaporation either by means of a water-bath, or in shallow vessels, at a moderate heat. But this mode of evaporation is always more or less objectionable, and should never be employed, except in cases where the principles of the plant are so fixed and unchangeable as to authorize their extraction by boiling.

Evaporation by means of the water-bath, from the commencement of the process, is safer than the plan just mentioned, as it obviates all danger of burning the extract; but as the heat is not supplied directly from the fire, the volatilization of the water cannot go on so rapidly, and the temperature being the same, or very nearly so, when the water-bath is kept boiling, there is greater risk of injurious action from the air. The use of the vapour-bath, as suggested by M. Henry, is perhaps preferable; as it requires a smaller consumption of fuel, and the heat imparted to the liquid, while sufficient to evaporate it, is less than 212°. We take the following description of the apparatus employed at the Central Pharmacy of Paris, from M. Chevallier's highly useful Manual. It consists of a covered boiler, containing water, the vapour of which is conducted through a pipe into evaporating vessels, communicating with each other by means of metallic tubes. These vessels have the form of an ordinary copper basin, over the top of which is soldered a shallow tin capsule intended to contain the liquor to be evaporated. The vapour from the boiler circulates through these vessels, and the water into which it condenses is allowed to escape through a stop-cock attached to the bottom of each vessel. From the last one of the series a tube passes into a vessel of water; so as to afford a slight pressure against the escape of any excess of vapour. The liquid to be evaporated is first distributed in two or three capsules, but when considerably concentrated is transferred to a single one, where it is stirred towards the close of the process to hasten the evaporation. The heat applied to the liquid, if there are four vessels, is in that nearest the boiler about 198° F., in the fourth or most remote, about 135°. An incidental advantage of this apparatus is, that it affords a large supply of distilled water, which may be used for extracting the active matter from fresh portions of the vegetable, or for other purposes.

A good plan of evaporation, though slow, is to place the liquid in a broad shallow vessel, exposed in a stove or drying room to a temperature of about 100°, or a little higher, taking care that the air have free access, in order to facilitate the evaporation. This mode is particularly applicable to all those cases in which maceration or infusion is preferred to decoction for extracting the active principles. Berzelius says that we may thus usually obtain the extract in the form of a yellowish transparent mass, while those prepared in the ordinary way are almost black, and are opaque even in very thin layers. Even when the liquid is boiled at first, the process may often be advantageously completed in this manner.

Plans have been proposed and carried into execution for performing evaporation without the admission of atmospheric air. The apparatus for evaporation in vacuo, invented by Mr. Barry, and described in the Lond. Journ. of Science and Arts, vol. viii. p. 360, is well calculated to meet this object, at the same time that, by removing the atmospheric pressure, it enables the water to rise in vapour more rapidly, and at a comparatively low temperature. Another method is to place the liquid under an exhausted receiver, together with some concentrated sulphuric acid, or chloride of calcium, which, by its affinity for water, assists the evaporation of the liquid. But from the expense and trouble of these modes of evaporation, they are not calculated for general use.

A more convenient plan of excluding the air, though it does not at the same time meet the object of reducing the requisite degree of heat, is to distil off the water in close vessels. Berzelius says that this is the best mode of concentration next to that *in vacuo*. Care, however, must be taken, that the fire be not too long applied, lest the extract should be burnt. The process should, therefore, be completed by means of the water-bath.

In the concentration of alcoholic solutions, distillation should always be performed; as not only is the atmospheric air thus excluded, but the alcohol is recovered, if not absolutely pure, certainly fit for the purpose to which it was originally applied. Here also the water-bath should be employed to obviate any possible risk of injury from the fire. When a decoction or infusion, and tincture of the same vegetable have been made separately, they should be separately evaporated to the consistence of syrup, and then mixed together, while they are of such a consistence as to incorporate without difficulty. The object of this separate evaporation is, that the spirituous extract may not be exposed to the degree of heat, or lengthened action of the air, which is necessary in the ordinary mode of concentrating the infusion or decoction.

In every instance, care should be taken to prevent any portion of the extract from becoming dry and hard on the sides of the evaporating vessel, as in this state it will not readily incorporate with the remaining mass. The heat, therefore, should be applied to the bottom, and not to the sides of the vessel.

3. *Condition and Preservation of Extracts.*

Extracts are prepared of two different degrees of consistence, soft so that they may be readily made into pills, and hard that they may be pulverized. Those obtained from the expressed juices of plants are apt to attract moisture from the air, in consequence of the deliquescent nature of the salts existing in the juice. They are thus rendered softer, and more liable to become mouldy upon the surface. Others, especially such as contain much chlorophylle, harden by time, in consequence of the escape of their moisture; and it not unfrequently happens that small crystals of saline matter are formed in their substance. Most extracts, especially those containing azotized principles, when left to themselves, are capable of producing nitrates. The air, moreover, exercises an unfavourable chemical influence over the softer extracts, which are enfeebled, and ultimately become nearly inert, by the same changes which they undergo more rapidly in the liquid state at an elevated temperature. If an extract be dissolved in water, and the liquid be saturated with common salt, or any other very soluble salt of difficult decomposition, the greater part of it is precipitated, in consequence of the insolubility of this class of substances in saline solutions. The precipitate may be again dissolved in pure water. (*Berzelius.*)

Extracts, in order that they may keep well, should be placed in glazed earthenware, glass, or porcelain jars, and completely protected from the access of the air. This may be effected by covering their surface with a layer of melted wax, or with a piece of paper moistened with strong spirit, then closing the mouth of the vessel with a cork, spreading wax or rosin over this, and covering the whole with leather, or a piece of bladder. (*Duncan.*) The dry extracts, being less liable to be affected by atmospheric oxygen, do not require so much care. The application of alcohol to the surface has a tendency to prevent mouldiness. A method of protecting extracts from the action of the air frequently resorted to, is to cover them closely with oiled bladder; but this, though better than to leave them uncovered, is not entirely effectual. Should the extract become too moist, it may be dried by means of a water-bath; should it, on the contrary, be too dry, the proper consistence may be restored by softening it in the same manner, and incorporating with it a little distilled water. (*Chevallier.*)

Extracts from recent plants should always be prepared at the season when the plant is medicinally most active; and a good rule is to prepare them once a year.

4. *Officinal Directions.*

The Pharmacopœia of the *United States* and that of the *London College*, give the following general directions.

"In the preparation of the extracts, evaporate the moisture, as quickly as possible, in a broad, shallow dish, by means of a water-bath, until they have acquired the consistence proper for forming pills; and towards the end of the process, stir them constantly with a spatula.

"Sprinkle upon the softer Extracts a small quantity of Alcohol." *U. S. Lond.*

The *Edinburgh College* gives separate directions for different classes of extracts under the heads of *Succi Spissati*, or inspissated juices; *Extracta per Aquam*, or watery extracts; and *Extracta per Aquam et Alcohol*, or spirituous extracts.

1. *Succi Spissati.* "Bruise the fresh substance, and compress it strongly in a hempen bag that it may yield its juice, which is to be placed in shallow vessels heated in boiling water saturated with muriate of soda, and immediately reduced to the consistence of thick honey. The mass, when cold, is to be placed in glazed earthen vessels, and moistened with stronger alcohol." *Ed.*

2. *Extracta per Aquam.* "Having sliced and bruised the substance, pour upon it eight times its weight of distilled water. Boil to one-half, and strain with strong expression. Immediately evaporate the decoction to the consistence of thick honey, in a bath of boiling water saturated with muriate of soda." *Ed.*

3. *Extracta per Aquam et Alcohol.* "Upon a pound of the substance, in powder, pour four times its weight of stronger alcohol. Digest for four days, and pour off the tincture. Boil the residuum in five pounds of distilled water for fifteen minutes, and strain the decoction, boiling hot, through linen. Repeat the boiling and filtration with an equal quantity of distilled water, and evaporate the liquor to the consistence of thin honey. Draw off the alcohol from the tincture by distillation, till it becomes equally thick; then mix the inspissated liquors; and in a bath of boiling water saturated with muriate of soda, evaporate to the proper consistence." *Ed.*

The *Dublin College* also places the inspissated juices under a distinct head, and gives directions for the watery extracts, under the title of *Extracta Simpliciora*, omitting, probably through inadvertence, the classification of the spiritous extracts which it also orders.

1. *Succi Spissati.* "The leaves used in the preparation of the inspissated juices should be gathered about the period when the herb begins to flower. The inspissation is best effected by evaporating the superfluous moisture with a *medium* heat by means of a vapour bath, and constantly stirring with a spatula towards the close of the process." *Dub.*

2. *Extracta Simpliciora.* "All simple extracts unless otherwise ordered, are to be prepared according to the following rule. Boil the vegetable matter in eight times its weight of water, till the liquid is reduced one-half; then express, and after the subsidence of the dregs filter: evaporate the liquor with a *superior* heat (between 200° and 212°) until it begins to thicken; finally, inspissate it with a *medium* heat (between 100° and 200°) obtained by a vapour-bath, frequently stirring, till it acquires the consistence proper for the formation of pills." *Dub.*

W.

EXTRACTUM ACONITI. *U. S. Lond.* SUCCUS SPISSATUS ACONITI NAPELLI. *Ed.* SUCCUS SPISSATUS ACONITI. *Dub.* *Extract of Aconite.*

"Take of fresh Aconite [leaves] *a pound.* Bruise it in a stone mortar, sprinkling on it a little water; then express the juice, and evaporate it to the proper consistence." *U. S.*

The directions of the *London* and *Dublin Colleges* are the same as the above. The *Edinburgh College* orders all its inspissated juices, with the exception of that of elder berries, to be prepared according to its general formula. The reader will find the general officinal directions of the United States and British Pharmacopœias, at the close of our introductory observations in relation to extracts. Among these observations, he will also find rules which may be of practical use in regulating the various steps of the process under consideration.

In relation to the preparation of this extract, as well as of all those derived from the expressed juices of narcotic plants, the following summary of the plan pursued by Mr. Battley, an experienced apothecary of London, may be of service. Having passed the expressed juice through a fine hair sieve, he places it immediately upon the fire. Before it boils, a quantity of green matter rises to the surface, which in some plants is very abundant. This is removed by a perforated tin dish and preserved. It ceases to appear soon after the liquid begins to boil. The boiling is continued till rather more than half the fluid has been evaporated, when the decoction is poured into a conical pan and allowed to cool. An abundant dark green precipitate forms, from which the supernatant liquid is poured off, and having been reduced one-half by a second boiling, is again allowed to stand. The precipitate which now falls is less green than the first. The remaining fluid is once more placed over the fire, and allowed to boil till it assumes the consistence of syrup, when it is removed. The matter at first collected by filtration, together with that precipitated, is now incorporated with it, and the whole placed in a metallic pan, and by means of a water-bath evaporated to the consistence of an extract. In the latter part of the process, care is necessary to prevent any part of the extract from hardening on the sides of the vessel, as it thus loses its fine green colour and becomes proportionably feeble.

The superiority of this plan over a continuous boiling is, that the portions of active matter which are deposited at different stages of the process, are subjected for a shorter time to heat than if allowed to remain in the liquor, and consequently are less deteriorated. The matter which coagulates before the fluid boils, is chiefly albumen, embracing portions of chlorophylle and of the undissolved vegetable fibre. It might probably be thrown away without diminishing the virtues of the extract; but as the chlorophylle, though itself inactive, has often associated with it a portion of the active principle, it is the most economical plan to incorporate it with the other matters.

Mr. Brande states that one Cwt. of fresh aconite yields about five pounds of extract. According to Geiger, one pound yields an ounce and a half.

When properly prepared, by means of a water-bath, this extract has a yellowish-brown colour, with a disagreeable narcotic odour, and the acrid taste of the plant. By the officinal process, however, which is that of Störck, the leaves are not exhausted of their active matter, as the residue after expression is still very acrid. The Prussian Pharmacopœia, therefore, directs the residue to be digested in alcohol, and the tincture to be mixed and evaporated with the expressed juice. The extract thus prepared is said to be more acrid and more active as a medicine. The extract of aconite may be given in the dose of one or two grains; but a safer plan is to begin with half a grain night and morning, to be gradually increased till the system is affected. Twenty grains or more have been given in the course of a day. W.

EXTRACTUM ALOES PURIFICATUM. *Lond.* EXTRACTUM ALOES HEPATICÆ. *Dub.* *Purified Extract of Aloes.*

"Take of Extract of the Aloe Spicata, in powder, *a pound;* Boiling Water, *a gallon.* Macerate for three days with a gentle heat; then strain the liquor, and set it by that the dregs may subside. Pour off the clear liquor, and evaporate it to a proper consistence." *Lond.*

The *Dublin College* prepares this extract according to the general directions. (See page 829.)

As the London College calls aloes itself an extract, it gives this preparation necessarily the title of the purified extract. The object of the process is to separate the resinous matter, the *apothême* of Berzelius, which is supposed to irritate the bowels, without possessing purgative properties; but the truth appears to be, that, when deprived of a small proportion of adhering extractive, it is quite inert. It cannot, therefore, injuriously affect the virtues of the medicine; and as it exists in comparatively small proportion, and during the process a part of the extractive becomes insoluble, the preparation may be considered as at best unnecessary. The dose of the purified aloes is from five to fifteen grains. W.

EXTRACTUM ANTHEMIDIS. *U. S. Lond.* EXTRACTUM ANTHEMIDIS NOBILIS. *Ed.* EXTRACTUM CHAMÆMELI. *Dub.* *Extract of Chamomile.*

Take of Chamomile [dried flowers] *a pound;* Water, *a gallon.* Boil down to four pints, and strain the liquor while hot; then evaporate to the proper consistence," *U. S.*

This is also the process of the *London College.* For the mode of conducting the evaporation as directed in the United States and London Pharmacopœias, and applied to all the extracts, see page 829. The *Edinburgh* and *Dublin Colleges* prepare this extract according to the general process of the former for *watery extracts,* of the latter for *simple extracts.* (See page 829.)

According to Mr. Brande, one Cwt. of dried chamomile flowers affords upon an average 48 pounds of extract.

This extract has a deep brown colour, and the bitter taste of chamomile, but is wholly destitute of aroma, the volatile oil having been entirely driven off during the process. It does not, therefore, possess the peculiar virtues of the flowers; but is simply a mild bitter, which may sometimes be advantageously combined with laxatives and mineral tonics in debilitated states of the digestive organs. The dose is from ten to twenty grains. An extract may be prepared, having the peculiar flavour as well as bitterness of chamomile, by macerating the flowers in water, and evaporating the infusion in vacuo. W.

EXTRACTUM ARTEMISIÆ ABSINTHII. *Dub.* *Extract of Wormwood.*

This extract, which is directed only by the *Dublin College,* is prepared from the tops of Wormwood according to the general formula of that College for *simple extracts.* (See page 829.) It retains, to a certain extent, the bitterness of the plant, without the strong odour and peculiar taste dependent on the volatile oil which is driven off by the boiling. It is, however, in no respect superior to other bitter extracts, and is very seldom used. The dose is from ten to twenty grains. W.

EXTRACTUM BELLADONNÆ. *U.S., Lond.* Succus Spissatus Atropæ Belladonnæ. *Ed.* Succus Spissatus Belladonnæ. *Dub.* *Extract of Deadly Nightshade.*

This is prepared from the fresh leaves of the *Atropa Belladonna* in the manner directed for the extract of aconite. (See *Extractum Aconiti.*)

Mr. Brande states that one Cwt. of fresh belladonna yields from 4 to 6 pounds of extract. According to M. Recluz, nearly ten parts may be obtained from one hundred.

The extract of belladonna employed in this couutry is brought chiefly from England. It has usually a dark-brown colour, a slightly narcotic not unpleasant odour, a bitterish taste, and a soft consistence which it long retains. Asparagin has been found in this extract. (*Journ. de Pharm.*, xxi. 178.)

Its medical properties and uses have been detailed under the head of Belladonna. In relation, however, to its local employment, it may be proper to add to what we have already stated, that it is recommended by N. Chaussier and others in cases of protracted labour depending on rigidity of the os uteri. The extract, mixed with simple ointment, in the proportion of two drachms to an ounce, is applied at intervals directly to the neck of the uterus. With a similar view of producing relaxation, it has been employed locally in spasm of the urethra and painful constriction of the rectum; but care is requisite not to introduce it too freely into the bowel. It is often advantageously employed, in the shape of plaster or ointment, in local pains of a neuralgic or rheumatic character. (See *Emplastrum Belladonnæ.*) The dose of the extract is uncertain on account of its exceedingly variable strength. The best plan is to begin with one-quarter or one-half of a grain, repeated two or three times a day, and gradually to increase the dose till the effects of the medicine are experienced. To a child two years old not more than one-twelfth of a grain should be administered at first.

Off. Prep. Emplastrum Belladonnæ. *Dub.* W.

EXTRACTUM CINCHONÆ. *U.S.* Extractum Cinchonæ Lancifoliæ. *Ed.* *Extract of Peruvian Bark.*

"Take of Peruvian Bark, in powder, *a pound;* Alcohol *four pints;* Water *a gallon.* Macerate the Peruvian Bark with the Alcohol for four days, and pour off the tincture. Boil the residuum in four pints of the Water for a quarter of an hour, and strain the liquor, while hot, through linen: repeat the boiling with the four remaining pints of Water, aud strain as before; then evaporate the decoction to the consistence of thin honey. Distil the Alcohol from the tincture till this attains a similar degree of thickness; then mix the inspissated liquors, and evaporate to the proper consistence." *U.S.*

The Extract of the *Edinburgh College*, which is prepared according to their general directions for extracts by water and alcohol (see page 829) differs from ours only in being procured exclusively from the pale bark, while the United States Pharmacopœia leaves the choice of the variety to the physician or apothecary. (See *General Observations*, page 833.) W.

EXTRACTUM CINCHONÆ. *Lond., Dub.* *Extract of Peruvian Bark.*

"Take of Bark of the Cinchona Lancifolia [Pale Bark], bruised, *a pound;* Water *a gallon.* Boil down to six pints, and strain the liquor while hot. In the same manner boil the residue four times in an equal quantity of water, and strain. Lastly, mix all the decoctions together, and evaporate the mixture until it acquires a proper consistence.

"This extract should be kept *soft*, so as to be fit for forming pills, and *hard*, that it may be pulverized." *Lond.*

The *Dublin College* takes a pound of coarsely powdered pale bark and six pints of water; boils for fifteen minutes, in a loosely covered vessel, and filters the decoction while hot; boils the residue again in an equal quantity of water, and filters as before; repeats the boiling and filtration in like manner a third time; then mixes the decoctions, and evaporates them to a prope consistence. This College gives the same directions with that of London, in relation to the different states in which the extract should be kept. (See *General Observations* below.) W.

EXTRACTUM CINCHONÆ RESINOSUM. *Lond. Resinous Extract of Peruvian Bark.*

"Take of Bark of the Cinchona Lancifolia [Pale Bark], bruised, *two pounds;* Rectified Spirit *a gallon.* Macerate for four days, and strain. Distil the tincture, by means of a water-bath, until the extract acquires a proper consistence." *Lond.*

General Observations on the Extracts of Peruvian Bark. Of the different officinal extracts of bark for which directions are given above, we decidedly prefer that of the United States and Edinburgh Pharmacopœias. The aqueous extract of the London and Dublin Colleges is an injudicious preparation. In the first place, the water does not nearly exhaust the bark, and in the second, the boiling favours the formation of an insoluble compound of starch and tannin, which carries with it a portion of the alkaline principles, and though retained in the extract, is probably less efficient as a medicine than a more soluble compound containing an equal proportion of the active matter. According to the suggestion of M. Henry, Jun., it is not improbable that the different colouring matters in the bark act in relation to the quinia and cinchonia the part of an acid, sharing at a high temperature these bases with the kinic acid, and forming with them insoluble if not inert compounds. Besides, we cannot by any means be certain that a long continued heat of 212° may not determine an actual decomposition of a portion of these alkalies, and the formation of new principles. The London process is more objectionable than the Dublin, in proportion as the boiling which it directs is longer continued.

The alcoholic extract of the London College is a good preparation, containing probably most of the active matter of the cinchona; but we consider it inferior to that of the United States Pharmacopœia, inasmuch as the latter must necessarily embrace an equal proportion of the active matter, and in consequence of the use of water as a solvent, after the alcohol has performed its office, has probably an additional quantity, which the latter fluid may have left behind.

A very good extract of bark was formerly prepared in the shops of Philadelphia, by macerating the cinchona for a considerable length of time in a large proportion of water, and slowly evaporating the infusion, by a very moderate heat, in large shallow dishes placed upon the top of a stove. Before the use of the sulphate of quinia had superseded that of most other preparations of bark, we employed this extract with success in the treatment of intermittents, and found ten grains of it equivalent to nearly a drachm of the powdered cinchona.

Mr. Brande informs us that one Cwt. of fine crown bark (best pale bark) yields, on an average, 28 pounds of watery extract, and 25 pounds of alcoholic extract. The same kind of bark gave to M. Recluz, out of 100 parts, by maceration with cold water, 12.5 parts on an average of extract, by infusion with boiling water about 9.4 parts, by decoction from 12.5 to 18.75 parts, and by maceration in diluted alcohol (22° B.) from 25 to 31.3 parts. But the length of time for which the bark is submitted to the action of the solvent must have considerable influence on the proportion extracted, and of this we are not informed in the table from which we have taken the above results. (See *Dict. des Drogues.*)

It is best that the bark should be only coarsely powdered when submitted to decoction or maceration; as in this state it is sufficiently penetrable by the solvent, and more readily separated after being exhausted. The extract should always be brought to the hard dry state in which it may be pulverized, as it is thus less apt to be injured by exposure; and in the state of powder may be more uniformly incorporated with other substances.

Medical Uses. The extract of Peruvian bark is at present much less employed than before the discovery of quinia. It is still, however, occasionally prescribed as a tonic in combination with other medicines; and as it possesses, when properly prepared, most of the principles as they exist in the bark itself, it may be used in preference to the sulphate of quinia, whenever it is supposed that the latter is incapable of exerting all the curative influence of cinchona. The dose is from ten to thirty grains, equivalent to about a drachm of the powdered bark. W.

EXTRACTUM COLOCYNTHIDIS. *Lond.* EXTRACTUM COLOCYNTHIDIS SIMPLEX. *Dub.* *Extract of Colocynth.*

"Take of Pulp of Colocynth *a pound;* Water *a gallon.* Boil down to four pints, and strain the liquor while hot; then evaporate it to a proper consistence." *Lond., Dub.*

The proportion of colocynth is too large, if the pulp only, without the the seeds, is intended; as, in consequence of the porous nature of the medullary matter, it absorbs nearly the whole of the water, and almost precludes the possibility of boiling as directed. Dr. Duncan found half a pound of colocynth to contain 2770 grains of seeds, which boiled by themselves yielded almost nothing to water, and 800 grains of pith, which was easily boiled in four pounds of water, but absorbed almost the whole of it. The decoction, when expressed, although it contained no starch, gelatinized on cooling. By boiling the residuum in four pounds of fresh water, he obtained a decoction, which, mixed with that previously obtained, yielded upon evaporation 360 grains of a pale-brown, semi-transparent, dry, elastic extract, of intense bitterness.

The decoction is ordered to be strained while hot, because the gelatinous consistence which it assumes on cooling prevents it from readily passing through the strainer. The Parisian Codex directs, instead of the decoction, an infusion prepared by maceration in cold water. But the aqueous extract of colocynth, however made, is not an eligible preparation, as water does not dissolve the active bitter principle in large proportion, while it takes up much inert matter, so that the extract is even feebler than colocynth itself, without having any peculiar merit to recommend it. Besides, according to Mr. Brande, it is invariably either mouldy, or so tough and hard as to resist trituration and formation into pills. It has no place in our national Pharmacopœia, and might with propriety be discarded from those of London and Dublin. It is little used. The dose is from five grains to half a drachm. W.

EXTRACTUM COLOCYNTHIDIS COMPOSITUM. *U.S., Lond., Dub.* *Compound Extract of Colocynth.*

"Take of Pulp of Colocynth [without the seeds], sliced, *six ounces;*

Aloes, in powder, *twelve ounces;* Scammony, in powder, *four ounces;* Cardamom, in powder, *an ounce;* Soap [Castile] *three ounces;* Diluted Alcohol *a gallon.* Macerate the Pulp of Colocynth in the Diluted Alcohol, with a gentle heat, for four days. Strain the liquor, and add to it the Aloes, Scammony, and Soap; then evaporate to the proper consistence, and, near the end of the process, mix the Cardamom with the other ingredients." *U.S.*

The processes of the *London* and *Dublin Colleges* correspond with the above except in phraseology. The former College, however, designates the Socotrine Aloes, the latter, the Hepatic.

Soap was not embraced in the formula of the first edition of our Pharmacopœia; but has been added in imitation of the London process, in order to improve the consistence of the mass, which it renders more soluble in the liquors of the stomach when hardened by time. It may possibly also serve the purpose of qualifying the action of the aloes. Diluted alcohol is a much better solvent of the active principle of colocynth than water. The proper consistence alluded to in the process, is that which is adapted to the formation of pills.

This extract is an energetic and safe cathartic, possessing the activity of its three purgative ingredients, with comparatively little of the drastic character of the colocynth and scammony. It may be still further and advantageously modified by combination with rhubarb, jalap, calomel, &c., with one or more of which it is very often united in prescription. In such combination it is much employed wherever an active cathartic is desirable, particularly in the commencement of fevers and febrile complaints, in congestion of the liver or portal system, and in obstinate constipation. In small doses it is an excellent laxative in that state of habitual costiveness depending on a want of the due irritability of the bowels, which often occurs in old people. The dose is from five to thirty grains, according to the effect to be produced, and the susceptibility of the bowels. A very eligible combination is the compound cathartic pill of the U.S. Pharmacopœia.

Off. Prep. Pilulæ Catharticæ Compositæ, *U.S.* W.

EXTRACTUM CONII. *U.S., Lond.* SUCCUS SPISSATUS CONII MACULATI. *Ed.* SUCCUS SPISSATUS CONII. *Dub.* *Extract of Hemlock.*

This is prepared from the fresh leaves of the *Conium maculatum*, in the manner directed for extract of aconite. (See *Extractum Aconiti.*)

Mr. Brande observes, in relation to the inspissated juices generally, that light pressure only should be employed in separating the juice from the leaves; as the extract is thus procured greener, of a less glutinous or viscid consistence, and, in his opinion, more active than when considerable power is used in the expression. With regard to this particular extract, he states that its preparation "almost necessarily requires the use of a steam-apparatus, for in a water-bath the evaporation is so prolonged as to injure it, and over the open fire it invariably suffers from too high a temperature." (*Manual of Pharmacy.*) No one of the extracts is more variable in its qualities than this. The season at which the herb is collected, the place and circumstances of its growth, the method of preparing the extract, are all points of importance, and are all too frequently neglected. (See *Conium.*) In this country the process is often very carelessly conducted; and we are told by Dr. A. W. Ives, that large quantities of an extract prepared by boiling the plant in water and evaporating the decoction, have been sold as the genuine drug. The apothecary should always prepare the extract himself, or procure it from persons in whom he can have entire confidence. That imported from London is usually the best.

Extract of hemlock should have a fresh olive colour, a strong narcotic somewhat fetid odour, and a bitterish saline taste. According to Brande, from three to five pounds are obtained from one Cwt. of the leaves. M. Recluz got rather more than an ounce from sixteen ounces. Of the medical properties and application of this extract, we have spoken under the head of Conium. The dose is three grains twice a day, to be gradually increased till evidences of its action upon the system are afforded. It may be administered in pill or solution. W.

EXTRACTUM GENTIANÆ. *U.S., Lond., Dub.* EXTRACTUM GENTIANÆ LUTEÆ. *Ed.* *Extract of Gentian.*

This is prepared from bruised gentian, in the manner directed for extract of chamomile. (See *Extractum Anthemidis.*)

The French Codex directs maceration in cold water, instead of decoction as ordered by the U.S. and British Pharmacopœias for extracting the virtues of the root; and MM. Guibourt and Cadet de Vaux obtained by the former method an extract not only greater in amount, but more transparent, more bitter, and possessing more of the colour and smell of the root than that prepared by the latter. Guibourt attributes this result to the circumstance, that as gentian contains little, if any starch, it yields nothing to boiling which it will not also yield to cold water, while decoction favours the combination of a portion of the colouring matter with the lignin. Gentian, according to Brande, yields half its weight of extract.

As ordinarily procured, the extract of gentian is nearly inodorous, very bitter, of a dark brown colour approaching to black, shining, and tenacious. It is frequently used as a tonic in the form of pill, either alone or in connexion with metallic preparations. The dose is from ten to thirty grains. W.

EXTRACTUM HÆMATOXYLI. *U.S. Lond.* EXTRACTUM HÆMATOXYLI CAMPECHIANI. *Ed., Dub.* *Extract of Logwood.*

This is prepared from the raspings of logwood, in the manner directed for extract of chamomile. (See *Extractum Anthemidis.*)

The evaporation should be carried so far, that the extract may be dry and brittle when cold. About twenty pounds of it are obtained from one Cwt. of logwood. (*Brande.*) It is of a deep ruby colour, and an astringent sweetish taste; and possesses all the medical virtues of the wood from which it is procured. If given in pills, these should be recently made, as, when long kept, they are said to become so hard as sometimes to pass unchanged through the bowels. The extract, however, is best administered in solution. The dose is from ten to thirty grains. This extract is said to be prepared largely in Yucatan and other parts of Mexico. (*Journ. of the Phil Col. of Pharm.* vi. 87.) W.

EXTRACTUM HELLEBORI NIGRI. *U.S., Ed.* *Extract of Black Hellebore.*

This is prepared from the bruised root of the *Helleborus niger*, in the manner directed for extract of chamomile. (See *Extractum Anthemidis.*)

The virtues of black hellebore are either not completely extracted by boiling water, or are deteriorated by decoction; for the watery extract is little, if at all stronger than the root. It operates as a drastic purge in the dose of twelve or fifteen grains, but is seldom employed.

The French Codex gives a formula for preparing the extract of hellebore, according to the method of Bacher. Two pounds of the root and half a pound of carbonate of potassa are digested, with a moderate heat, for twelve hours, in eight pounds of alcohol of 22° B.; the tincture is strained with expression; the residuum is again digested with eight pounds of white wine for twenty-four hours; the wine is expressed, and having stood four hours to settle is decanted; the liquors are then mixed, and with a gentle heat evaporated to the consistence of an extract. One ounce of this extract, mixed with the same quantity of myrrh, and with ten scruples of the powdered leaves of the Centaurea benedicta, and made into pills of one grain each, constitutes the preparation known as the *tonic pills of Bacher*, formerly much used in amenorrhœa and dropsy, and probably not without advantage, especially in the former of these diseases. The dose is from ten to twenty pills during the day. An additional quantity of diluted alcohol might, without disadvantage, be substituted for the wine in the preparation of the extract. W.

EXTRACTUM HUMULI. *Lond.* EXTRACTUM HUMULI LUPULI. *Dub.* *Extract of Hops.*

"Take of Hops *four ounces;* boiling Water *a gallon.* Boil down to four pints, and strain the liquor while hot; then evaporate to a proper consistence." *Lond.*

The *Dublin College* orders this extract to be prepared according to its general formula for simple extracts. (See p. 829.)

Since the discovery of the fact that the active properties of hops reside chiefly in the lupulin, this extract has not been deemed an eligible preparation, and has been little used. It has the peculiar bitterness of the strobiles, without their aroma. Lupulin may be advantageously substituted for it in all cases in which it was formerly employed. Mr. Brande says that the average product of one Cwt. of hops is forty pounds of the extract. The dose is from ten to thirty grains. W.

EXTRACTUM HYOSCYAMI. *U. S.*, *Lond.* SUCCUS SPISSATUS HYOSCYAMI NIGRI. *Ed.* SUCCUS SPISSATUS HYOSCYAMI. *Dub.* *Extract of Henbane.*

This is prepared from the fresh leaves of the *Hyoscyamus niger*, in the manner directed for extract of aconite. (See *Extractum Aconiti.*)

It is seldom if ever made in this country, being derived chiefly from England. Mr. Brande says that one Cwt. of the fresh herb affords between four and five pounds. M. Recluz obtained about one part from sixteen.

The extract, as it reaches us, is of a dark olive colour almost black, of a narcotic rather unpleasant odour, and a bitterish, nauseous, slightly saline taste. It retains its softness for a long time; but at the end of three or four years becomes dry, and exhibits, when broken, small crystals of nitrate of potassa and chloride of sodium. (*Recluz.*) Like all the inspissated juices it is of variable strength, according to its age, the care used in its preparation, and the character of the leaves from which it was procured. (See *Hyoscyamus.*) In its use, therefore, it is necessary to begin with a moderate dose, two or three grains for instance, and gradually to increase the quantity till some effect is experienced, and the degree of efficiency of the particular parcel employed is ascertained. It is usually given in pill. W.

EXTRACTUM JALAPÆ. *U.S.*, *Lond.*, *Dub.* EXTRACTUM CONVOLVULI JALAPÆ. *Ed.* *Extract of Jalap.*

"Take of Jalap, in powder, *a pound;* Alcohol *four pints;* Water *a gallon.* Macerate the Jalap in the Alcohol for four days, and pour off the tincture. Add the Water to the residue, and boil down to two pints; then strain the tincture and decoction separately, and distil the former and evaporate the latter, till they acquire the consistence of thin honey. Lastly, mix them together, and evaporate to the proper consistence.

"Of this Extract, let a portion be kept in a *soft* state, fit for the formation of pills; and another *hard*, so that it may be pulverized." *U.S.*

The processes of the *London* and *Dublin Colleges* for this extract, correspond with the above in all essential points. The *Edinburgh College* prepares it according to their general formula for spirituous extracts, (see page 829,) which will afford a similar result.

Infusion in water might be advantageously substituted for the decoction to which the residuum of the jalap, after having been treated with alcohol, is subjected; as the virtues of the root may be thus extracted without the amylaceous matter, which serves only to augment the bulk, and impede the filtration or straining. But, according to M. Cadet de Gassicourt, water at ordinary temperatures acts so slowly, that fermentation takes place before the active matter is all dissolved. It is, therefore, necessary to digest with a heat of about 90° or 100° F., which, while it is insufficient for the solution of the starch, enables the water to take up all that it is desirable to extract. By the previous removal of the resin by means of alcohol, it is probable that the action of the water is facilitated. One Cwt. of jalap affords, according to Mr. Brande, about fifty pounds of aqueous extract and fifteen of resin. The product of the former is somewhat less by infusion than decoction; and the extract is proportionably stronger.

The extract of jalap is of a dark brown colour, slightly translucent at the edges, and tenacious when not perfectly dry. It has the medical properties of the root; but is not often exhibited alone, being chiefly used as an ingredient of purgative pills, for which it is adapted by the comparative smallness of its bulk. The dose is from ten to twenty grains, or rather more than half that of jalap.

Off. Prep. Pilulæ Catharticæ Compositæ, *U.S.*; Pulvis Scammonii Compositus, *Dub.*, *Lond.* W.

EXTRACTUM JUGLANDIS. *U.S.* *Extract of Butternut.*

This is prepared from the sliced inner bark of the root of the *Juglans cinerea*, in the manner directed for extract of chamomile. (See *Extractum Anthemidis.*)

Most of this extract kept in the shops is prepared by the country people, who are said to use the bark of the branches, and even the branches themselves, instead of the inner bark of the root, as directed by the Pharmacopœia. The heat is also improperly regulated, being applied too vigorously, or continued too long, so that the preparation is often injured. That it should have proved uncertain in the hands of many physicians is, therefore, not a matter of surprise. It should always be prepared by the apothecary, and from the inner bark of the root gathered in May or June.

The extract of butternut is of a black colour, sweetish odour, and bitter astringent taste. In the dose of twenty or thirty grains it acts as a mild cathartic. (See *Juglans.*) W.

EXTRACTUM LACTUCÆ. *Lond.* SUCCUS SPISSATUS LACTUCÆ SATIVÆ. *Ed.* *Extract of Lettuce.*

"Take of fresh Lettuce Leaves *a pound.* Bruise them in a stone mortar, sprinkling a little water upon them; then express the juice, and evaporate it unstrained, until it acquires a proper consistence." *Lond.*

This extract is prepared by the *Edinburgh College* from the plant, according to their general formula for the preparation of inspissated juices. (See page 829.)

Its claims to favourable notice are at least very questionable. Consisting chiefly of the common sap of the plant, which is inert, with a variable, but always small proportion of the milky secretion, on which the activity of lettuce depends, it is at best a feeble and uncertain preparation; and might very well be dispensed with. Lactucarium possesses all its virtues, with much greater strength and uniformity of action. It is accordingly used in this country to the exclusion of the extract. The dose of the latter is from five to fifteen grains. W.

SUCCUS SPISSATUS LACTUCÆ VIROSÆ. *Ed.* *Inspissated Juice of Strong-scented Lettuce.*

This is prepared from the plant, according to the general formula of the *Edinburgh College* for the preparation of their inspissated juices. (See page 829.)

It is not used in this country. The inspissated juice of our own wild lettuce—*Lactuca elongata*—has been proposed as a substitute, but has not found a place among the officinal preparations. (See *Lactuca Virosa* and *Lactuca Elongata.*) W.

EXTRACTUM NUCIS VOMICÆ. *Dub.* *Extract of Nux Vomica.*

"Take of Nux Vomica, rasped, *eight ounces;* Proof Spirit *two pints.* Digest in a close vessel for three days; filter the liquor, and express the remainder by a press. Add to the residue one pint and a half of Proof Spirit, digest for three days, and express. Mix the liquors, and having reduced them by distillation to one-fourth, evaporate to a proper consistence." *Dub.*

This extract, which is peculiar to the Dublin Pharmacopœia, is an active preparation of nux vomica, though not always of uniform strength, owing to the variable proportion of strychnia in the article from which it is prepared. M. Recluz obtained from sixteen ounces of the nux vomica, the average product of one ounce and a quarter. The dose of the extract is from half a grain to two grains, to be repeated three times a day. W.

EXTRACTUM OPII. *Lond.* EXTRACTUM OPII AQUOSUM. *Dub.* *Extract of Opium.*

"Take of Opium *sixteen ounces;* Water *a gallon.* Add a little Water to the Opium, and macerate for twelve hours that it may become soft; then, adding gradually the remainder of the Water, rub them until they are thoroughly mixed, and set the mixture by that the dregs may subside; lastly, strain the liquor, and evaporate it to a proper consistence." *Lond.*

"Take of Opium, sliced, *two ounces;* Boiling Water *a pint.* Rub the Opium with the Water for ten minutes, and, after a short interval, pour off the liquor. Triturate the remaining Opium with an equal quantity of boiling Water, for the same length of time, and pour off the liquor as before. Repeat the trituration a third time; then mix the liquors, and expose the mixture to the air for two days in an open vessel. Lastly, filter through linen, and evaporate the filtered liquor slowly to the consistence of an extract." *Dub.*

Of these two processes, that of the Dublin College is undoubtedly the best, as water boiling hot extracts more of the soluble principles of opium than at a lower temperature. M. Recluz obtained from sixteen ounces of the drug an average product of nine ounces by hot water, and only six by cold. But we can discover no advantage which either preparation has over opium itself. Though the dose may be somewhat smaller, yet that of opium is sufficiently small; and if there be any distinct principle in this drug which modifies in an unpleasant manner the action of the morphia, it is not left behind in the preparation of the watery extract. Nor has this preparation the advantage of greater uniformity, as the gum, extractive, &c., taken up by the water, bear no fixed proportion to the anodyne principle. It is highly probable, moreover, that the opium is not completely exhausted by either process. It certainly is not by that of the London College; for morphia may be extracted from the residuum of the operation. (*Brande.*) In the preparation, therefore, of the extract of opium, there is a loss of time and of active matter, without any equivalent gain; and there is the further disadvantage, that, as the extract does not possess equally with opium those external characters by which its quality may be decided, it is more liable to adulteration. We should, therefore, in every instance, prefer opium to the extract; but it is necessary that the latter should be selected of good quality, and should be freed from all adhering extraneous matters.

Under the impression that the stimulating and unpleasant effects of opium are owing to the narcotin, it has been proposed to separate this principle by submitting the extract to the operation of ether, which dissolves the narcotin and leaves the morphia with the other ingredients. Robiquet employed cold ether; but M. Dublanc; convinced that the whole of the narcotin was not thus extracted, proposed the following plan. "Take of watery extract of opium 16 ounces; dissolve it in 8 ounces of distilled water; introduce the solution into the water-bath of a still; pour upon it 104 ounces of pure ether; distil off 24 ounces of the ether; take apart the apparatus and decant the ether which floats on the top of the extract; wash the latter while hot with the distilled ether; concentrate the residual matter, dissolve it in distilled water, filter the solution, and evaporate to a proper consistence." It is very doubtful, however, whether any useful end is gained by this expensive operation, as it is not by any means conclusively settled that the narcotin does in fact produce the unpleasant effects which have been attributed to it; and even admitting the fact, the preparations of morphia, which are of uniform strength, are greatly preferable to the *denarcotized extract.*

The dose of the extract of opium prepared by the Dublin process is about one-half that of opium itself. The London extract, according to Brande, is never stronger, and is sometimes weaker than opium. W.

EXTRACTUM PAPAVERIS. *Lond.* EXTRACTUM PAPAVERIS SOMNIFERI. *Ed.* *Extract of Poppy.*

"Take of Poppy Capsules, freed from their seeds, and bruised, *a pound;* Boiling Water *a gallon.* Macerate for twenty-four hours, then boil down to four pints, strain the liquor while hot, and evaporate it to a proper consistence." *Lond.*

The *Edinburgh College* prepares the Extract of Poppy from the capsules prepared as above, according to their general formula for watery extracts. (See page 829.)

Mr. Brande observes, in relation to this extract, that if prepared over the open fire it is often nearly inert. He states, moreover, that it is apt to be of a troublesome consistence, too hard to be formed into pills, and too tough to be pulverized; and advises that it should always be carefully dried till it becomes sufficiently brittle to admit of being reduced to powder. One Cwt. of the capsules, without the seeds, yields, according to this author, the average product of 35 pounds of extract.

This preparation is little used in the United States. It possesses the virtues of opium, but is much inferior and less uniform in strength. The dose is from five to ten grains. W.

EXTRACTUM PODOPHYLLI. *U.S.* *Extract of May-apple.*

This is prepared from the powdered root of the *Podophyllum peltatum*, in the manner directed for the Extract of Jalap. (See *Extractum Jalapæ.*)

It is possessed of the purgative properties of the root, and may be given in the dose of from five to fifteen grains, but is little employed. It might be substituted in all cases for the extract of jalap. W.

EXTRACTUM QUASSIÆ. *U.S.* *Extract of Quassia.*

This is prepared from the raspings of Quassia, in the manner directed for the extract of chamomile. (See *Extractum Anthemidis.*)

According to M. Recluz, sixteen ounces of quassia yield by infusion in water seven drachms of extract; by maceration in alcohol of 19° Baumé, two ounces five drachms and a half. The difference between these quantities is so great that we suspect somem istake in the table of the Dictionnaire des Drogues from which we quote.

The extract of quassia is dark-brown or black, and excessively bitter. It is apt to become dry and disposed to crumble by time. It concentrates a greater amount of tonic power within a given weight than any other extract of the simple bitters; and may therefore be given with great advantage in cases in which it is desirable to administer this class of substances in as small a bulk, and with as little inconvenience to the patient as possible. The dose is about five grains, and should be given in the form of pill. W.

EXTRACTUM QUERCUS. *Dub.* *Extract af Oak Bark.*

This is prepared from the bark of the *Quercus Robur*, according to the general formula given by the Dublin College for the preparation of the *simple extracts*. (See page 829.)

The Dublin College alone orders this preparation, which may be considered as quite superfluous. The Quercus Robur, the bark of which is directed, is not a native of this country; but were it desirable to obtain the extract, the bark of our white oak—*Quercus alba*—might be advantageously substituted. The dose is from ten grains to a drachm. W.

EXTRACTUM RHEI. *Lond.*, *Dub.* *Extract of Rhubarb.*

"Take of Rhubarb Root, powdered, *a pound;* Proof Spirit *a pint;* Water *seven pints*. Macerate for four days with a gentle heat, then strain, and set the liquor by that the dregs may subside. Pour off the clear liquor, and evaporate it to the proper consistence." *Lond.*, *Dub.*

Rhubarb yields all its active matter to water and alcohol united; but as the proportion of the root insoluble in these fluids is only about 30 per cent. (20 according to Brande) the extract can be little stronger than rhubarb itself, even allowing that the active matter is not injured or dissipated in the process of its preparation. Unless the evaporation is performed with great care and with a very moderate heat, it is certain that this latter effect is produced to a greater or less extent, and the extract thus becomes even less efficient than the root. Among other consequences which result from the boiling temperature, is the formation of a compound of the tannin and starch which is insoluble in cold water, and upon its precipitation probably carries with it a portion of the purgative principle. There is, moreover, reason to believe that this principle is volatilizable by heat, and that a portion of it escapes with the vapour. This extract may, therefore, be very well dispensed with. It is not directed by the United States or Edinburgh Pharmacopœia. The only advantage, if it be one, which it possesses over powdered rhubarb is, that it may be given in solution; and the same object may be accomplished by employing the root itself in the state of infusion. The dose of the extract is from ten to thirty grains. W.

EXTRACTUM RUTÆ. *Dub.* EXTRACTUM RUTÆ GRAVEOLENTIS. *Ed.* *Extract of Rue.*

This is prepared by the *Edinburgh* and *Dublin Colleges* from the herb, according to their respective general formulæ for the preparation of the watery or simple extracts. (See page 829.)

The volatile oil, upon which the stimulant and antispasmodic properties of rue depend, is driven off in the preparation of the extract, which, therefore, answers no other purpose than that of a bitter tonic; and even in this respect it is inferior to the other bitter extracts. It is not used in this country. The dose is from ten to twenty grains. W.

SUCCUS SPISSATUS SAMBUCI. *Dub.* SUCCUS SPISSATUS SAMBUCI NIGRI. *Ed.* *Inspissated Juice of Elder.*

This is prepared by the Dublin College from fresh ripe elder berries in the same manner with the inspissated juice of aconite. (See *Extractum Aconiti.*)

The *Edinburgh College* orders *five parts* of the juice of ripe elder berries to be mixed with *one part* of refined sugar, and evaporated by a gentle heat to the consistence of pretty thick honey.

The elder berries employed in Europe are those of the *Sambucus nigra;* but the berries of the *Sambucus Canadensis*, which is a native of this country, will answer equally well. For the uses of this extract the reader is referred to the article *Sambucus* in the Materia Medica. W.

EXTRACTUM SARSAPARILLÆ. *Lond.*, *Dub.* *Extract of Sarsaparilla.*

"Take of Sarsaparilla root, sliced, *a pound;* Boiling Water *a gallon.* Macerate for twenty-four hours, and boil down to four pints; then strain the liquor while hot, and evaporate to a proper consistence." *Lond.*, *Dub.*

This extract can have little or no effect upon the system, as the active matter of sarsaparilla is either destroyed by chemical change or driven off at the heat of boiling water. Besides, it appears from the experiments of Hancock and others, that water is incapable of exhausting the root, and waste would be incurred, even admitting that the extract possessed some efficiency. Very different quantities have been obtained from different varieties of sarsaparilla, and even from different parcels of the same variety; but as the matter taken up by boiling water consists chiefly of starch, no inference as to the relative value of any particular specimen of the root can be drawn from a knowledge of the quantity of extract which it is capable of affording. From ten grains to a drachm of this preparation may be given for a dose.

A *spirituous extract* of sarsaparilla has been proposed by M. Beral, which probably contains the active matter of the root, and which well deserves the attention of pharmaceutists and physicians. It is prepared in the following manner. "Take of dilute alcohol of 20° B. [sp. gr. 0.9336] *sixteen pounds;* sarsaparilla, properly prepared, *two pounds.* Macerate the sarsaparilla in the dilute alcohol for a month; then decant, and filter through paper. Distil the tincture so as to draw off the alcohol, and concentrate the remaining liquid by means of a water-bath till it attains the consistence of a soft extract. The product is usually four ounces [a quarter of a pound]." (*Journ. de Pharm.* xv. 657.) The diluted alcohol extracts all the virtues of the root, leaving the inert fecula which encumbers the extract obtained by decoction; while the temperature requisite for the concentration of the tincture is insufficient to destroy the active principle. As the product of this operation is about one-eighth of the sarsaparilla employed, a drachm of the extract represents an ounce of the root. From ten to twenty grains of it may be given three or four times a day. We have ascertained by actual observation that it possesses in a high degree the acrid taste of sarsaparilla. W.

EXTRACTUM SARSAPARILLÆ FLUIDUM. *Dub.* *Fluid Extract of Sarsaparilla.*

"Take of the Root of Sarsaparilla, sliced, *a pound;* Water *twelve pints.* Boil them together for an hour, and pour off the liquor; then add twelve pints of water, and boil and decant as before. Express the liquor strongly from the residuary matter, and having mixed the decoctions, set the mixture by that the dregs may subside; then evaporate by continued boiling to thirty ounces [fluidounces], and add two ounces [fluidounces] of Rectified Spirit." *Dub.*

It has lately become very customary to employ a concentrated liquid preparation of sarsaparilla, under the name of *fluid extract.* It was probably in order to give some regularity to popular practice in this respect, that the Dublin College adopted the above process in the last edition of their Pharmacopœia. It is, however, to be regretted, that the preparation is not more in conformity with our present knowledge in relation to the pharmaceutical management of this root. There can be little doubt as to the almost total inefficiency of the fluid extract of the Dublin College. We should ourselves prefer the solid extract prepared according to the formula of M. Beral, detailed under the last head, to any concentrated liquid preparation; as we cannot be certain that the active principle is held in solution by a very small proportion of water, and if it be merely suspended, there may be a risk that due agitation may not be always practised in dispensing and administering the medicine. But if the popular inclination to this mode of preparation must be gratified, we should give a decided preference to the following formula of William Hodgson Jun. over any other which we have seen.

"Take of Sarsaparilla Root, bruised, *sixteen ounces;* Liquorice Root, bruised, Guaiacum Wood, rasped, Bark of Sassafras Root, each, *two ounces;* Mezereon *six drachms;* Diluted Alcohol *eight pints.* Digest for fourteen days at a common temperature; then strain, express, and filter. Evaporate the tincture in a water-bath to twelve fluidounces; then add eight ounces of white sugar, and remove from the fire as soon as the sugar is dissolved." (*Journ. of the Phil. Col. of Pharm.* ii. 285.)

Mr. Hodgson observes, that during the process a small quantity of resin separates and adheres to the sides of the vessel, apparently derived from the guaiacum wood. The advantages of this process are, that by means of the alcohol all the virtues of the root are extracted, while the low temperature required in its evaporation is not sufficient to impair these virtues. The preparation has been used in Philadelphia with great apparent advantage in secondary syphilis. The dose is a fluidrachm, equivalent to a drachm of the root, three or four times a day. W.

EXTRACTUM SPARTII SCOPARII. *Dub.* *Extract of Broom Tops.*

This is prepared from the tops of the *Spartium Scoparium,* according to the general formula of the *Dublin College* for the preparation of their simple extracts. (See page 829.)

It has laxative and diuretic properties; but is not employed in this country and seldom in Europe. The dose is from thirty grains to a drachm. W.

EXTRACTUM STRAMONII. *U.S., Lond., Dub.* *Extract of Thorn-apple.*

This is prepared, according to the U. S. Pharmacopœia, from fresh thorn-apple leaves, in the manner directed for extract of aconite. (See *Extractum Aconiti.*)

The *London* and *Dublin Colleges* prepare the extract from the *seeds*, according to the following formula. "Take of Thorn-apple Seeds *a pound;* Boiling Water *a gallon.* Macerate for four hours in a covered vessel near the fire; then take out the seeds, and after having bruised them in a stone mortar, return them to the liquor. Boil down to four pints, and strain the decoction while hot. Finally, evaporate to a proper consistence."

The extract of the U. S. Pharmacopœia, like the other inspissated narcotic juices, is an uncertain preparation, varying in strength according to the care used in conducting the process, and to the season at which the leaves are collected. M. Recluz obtained half an ounce of the extract from sixteen ounces of the leaves. The dose is a grain night and morning, to be gradually increased till it affects the system.

The extract of the seeds is more active in the same dose than that of the leaves, and would probably be still more efficient if prepared by maceration in diluted alcohol, instead of decoction in water as ordered by the London and Dublin Colleges. According to the table of Recluz, sixteen ounces of the seeds afford two ounces and two drachms of extract by maceration in diluted alcohol, and one ounce and a half by decoction. The dose to begin with is a quarter or half a grain twice a day, to be gradually increased. W.

EXTRACTUM TARAXACI. *U.S. Lond., Dub.* *Extract of Dandelion.*

This is prepared, according to the U. S. Pharmacopœia, from the fresh root of the *Leontodon Taraxacum*, in the manner directed for extract of chamomile. (See *Extractum Anthemidis.*)

The *London* process differs from that for extract of chamomile only in requiring a maceration of twenty-four hours previously to boiling. The *Dublin College* prepares the extract from both the herb and root, according to their general formula for the simple extracts. (See page 829.)

The extract is undoubtedly stronger, prepared from the root alone than from the whole plant. The month of August is the proper season for preparing it. Mr. Houlton, in a communication to the London Medico-Botanical Society, states that at this period the bruised roots yield by pressure nearly one-third of their weight of a thick cream-coloured fluid, in which the medical virtues reside. (*Lond. Med. and Surg. Journ.* vi. 78.) It is probable that this juice would afford by inspissation an extract much stronger than that prepared by the ordinary method. The product, however, would be much smaller. Mr. Brande informs us that one Cwt. of the fresh root affords from twenty to twenty-five pounds of extract by decoction in water.

This extract deteriorates by keeping, and should therefore be renewed annually. It is most conveniently given dissolved in cinnamon or mint water. The dose is twenty or thirty grains three times a day. (See *Taraxacum.*) W.

FERRUM.

Preparations of Iron.

LIMATURA FERRI PURIFICATA. *Ed.* *Purified Iron Filings.*

"Place a sieve over Iron Filings, and apply a Magnet, so that the Filings may be attracted upwards through the sieve." *Ed.*

The common iron filings, obtained from the workshops, are generally mixed with particles of brass and other substances, and hence require to be purified for medicinal use; but the above process effects this object imperfectly. The magnet will unquestionably attract the particles of iron; but these will often have attached to them certain impurities, which are carried up with them. The only way to obtain pure iron filings is to file a piece of pure iron with a clean file. The Paris Codex directs iron in an impalpable powder, prepared by porphyrizing bright and clean iron filings without water, and in dry weather. A dull black powder is formed, which must be carefully preserved from moisture. For the medical properties of iron filings, see *Ferrum* and *Ferri Ramenta* in the first part of this work. The dose is from five to twenty grains.

Off. Prep. Sulphas Ferri, *Ed.;* Tartras Potassæ et Ferri. *Ed.* B.

FERRI OXYDUM NIGRUM. *Dub.* OXIDUM FERRI NIGRUM PURIFICATUM. *Black Oxide of Iron.*

"Wash the Scales of the Oxide of Iron, found at the blacksmith's anvil, with water; and having dried them, separate them from impurities by means of a magnet. Then reduce them to powder, of which the finest particles are to be collected in the manner directed for the preparation of chalk. *Dub.*

"Let the Scales of the Oxide of Iron, found at the blacksmith's anvil, be purified by the application of a magnet; so that the smaller and purer Scales alone may be attracted." *Ed.*

The nature and composition of the scales of iron have been explained under the head of *Ferrum. Oxydi Squamæ.* By washing, they are freed from accidental impurities; and as they are not at the maximum of oxidation, they are capable of further purification by the use of the magnet, after which they are reduced to an impalpable powder, or left in the form of scales.

This preparation is not the regular black oxide, and besides, frequently contains metallic iron. A more uniform black oxide, and therefore preferable for medicinal use, is obtained by the following formula of the Paris Codex, adopted from Guibourt. Take of iron filings any quantity. Triturate them in a mortar, and then place them in a wide vessel of earthenware or porcelain. Pour water on them, until this liquid runs off perfectly limpid. Then incline the vessel a little, compress the filings, and allow them to drain for some miuutes; after which replace the vessel, stir the filings with an iron spatula, and add from time to time sufficient water to keep them moist. At the end of four or five days wash the filings to remove the black oxide formed and collect it on a filter. Lastly, compress the oxide and dry it.

Medical Properties and Uses. Black oxide of iron, when properly prepared, dissolves readily in the stomach, and is one of the best ferruginous preparations. Its general remediate powers coincide with those of the other chalybeates. (See *Ferrum.*) The dose is from five to twenty grains, two or three times a day.

Off. Prep. Tinctura Muriatis Ferri. *Ed.* B.

FERRI OXYDUM RUBRUM. *U.S.* OXIDUM FERRI RUBRUM. *Ed.* FERRI OXYDUM RUBRUM. *Dub.* *Red Oxide of Iron.*

"Take of Sulphate of Iron *any quantity.* Put it in a crucible, and expose it to an intense heat, till it is converted into a red substance. Wash this with boiling water, and afterwards dry it." *U.S.*

The *Edinburgh College* directs its officinal *dried* sulphate of iron to be violently heated, until it passes into a very red matter, and omits the ablution.

"Expose Sulphate of Iron to heat, until the water of crystallization is expelled. Then roast it by an intense fire as long as acid vapours arise. Wash the red oxide until the washings, when examined by litmus, appear free from acid. Lastly, dry it on bibulous paper." *Dub.*

When sulphate of iron, or *green vitriol,* is heated, it swells up, and undergoes the aqueous fusion, and afterwards, by losing its water of crystallization, becomes a dry white mass, consisting of anhydrous sulphate of iron. This, by the application of a strong heat, is decomposed; the iron becomes peroxidized at the expense of part of the acid, and sulphurous and sulphuric acids are given off. The peroxide, however, is not perfectly pure, but still contains a small portion of acid, to remove which it requires to be washed.

Properties, &c. Red oxide of iron is a reddish-brown, tasteless, insoluble powder, called *colcothar* in commerce. It should not be deliquescent, and should dissolve in muriatic acid, without effervescence. If it contain copper, its muriatic solution will deposite this metal on a bright rod of iron. It consists of two equiv. of iron 56, and three of oxygen 24=80. It is used only in the preparation of other compounds.

Off. Prep. Emplastrum Ferri, *U.S., Ed., Dub.;* Ferrum Ammoniatum, *U.S., Ed.* B.

FERRI ACETAS. *Dub.* *Acetate of Iron.*

"Take of Carbonate of Iron *one part;* Acetic Acid *six parts.* Digest for three days, and filter." *Dub.*

As the carbonate of iron contains both oxides of the metal, this preparation is a mixed solution of the protacetate and peracetate of iron. From comparative experiments made by Dr. Perceval of Dublin, it was found that the carbonate was more soluble in acetic acid than the oxides of iron or the metal, and hence it was selected for this formula. Of ten grains of the following ferruginous preparations digested in two drachms of acetic acid, sp. gr. 1.065, half a grain was dissolved of the scales of iron, one and a quarter grains of the red oxide, three and a quarter of iron filings, and the *whole* of the carbonate.

Properties, &c. This solution has a deep red colour, and an acid and strongly chalybeate taste. When exposed to heat it yields acetic acid. It possesses the general medical properties of the preparations of iron. The dose is from ten to twenty-five drops, taken in water. It is not used in this country. B.

FERRI ACETATIS TINCTURA. *Dub.* *Tincture of Acetate of Iron.*

"Take of Acetate of Potassa *two parts;* Sulphate of Iron *one part;* Rectified Spirit *twenty-six parts.* Rub the Acetate of Potassa and Sulphate of Iron together in an earthenware mortar, until they unite into a mass. Dry this with a medium heat, and triturate it with the Spirit. Digest the mixture in a well stopped bottle for seven days, shaking it occasionally. Lastly, pour off the tincture from the sediment, and preserve it in a well stopped bottle." *Dub*

This preparation was introduced into the Dublin Pharmacopœia by Dr. Perceval. In the process, a double decomposition takes place between the salts employed, resulting in the formation of the acetate of iron which dissolves in the spirit, and sulphate of potassa which remains behind, being insoluble in that menstruum. The tincture also contains a portion of acetate of potassa; more of this salt being employed than is necessary to decompose the sulphate of iron.

Properties. This tincture is a transparent liquid, of a dead claret colour, and strong chalybeate taste. When evaporated to dryness, it yields a saline matter, which is whitish from the presence of acetate of potassa. It is extremely liable to spontaneous decomposition, and is decomposed by the alkalies and their carbonates, the strong acids, and the astringent vegetable infusions.

Medical Properties and Uses. This preparation is represented to be an agreeable chalybeate; but it possesses no particular virtue, which can give it any advantage over other medicines of the same class. The dose is from one to two teaspoonfuls, mixed with water or other convenient vehicle. B.

TINCTURA ACETATIS FERRI CUM ALCOHOL. *Dub.* *Tincture of Acetate of Iron with Alcohol.*

"Take of Sulphate of Iron, Acetate of Potassa, each, *an ounce;* Alcohol *two pints.* Rub the Acetate of Potassa and Sulphate of Iron together in an earthenware mortar, until they unite into a soft mass; then dry this with a medium heat, and as soon as it has grown cold, triturate it with the alcohol. Digest the mixture in a well stopped bottle for twenty-four hours, shaking it occasionally. Lastly, pour off the clear tincture from the sediment, and keep it in a well stopped bottle." *Dub.*

This formula is nearly the same with the last; the points of difference being that equal weights of the saline materials are employed; and the menstruum is the alcohol of the *Dublin* College, and not rectified spirit. The double decomposition takes place as in the preceding preparation, and with the same results; but here, instead of there being an excess of acetate of potassa to enter into the tincture, there is an excess of sulphate of iron. The acetate of iron formed is a mixture of protacetate and peracetate; but the latter only is soluble in the strong alcohol of the Dublin College. Hence this tincture may be viewed as an alcoholic solution of the peracetate of iron. It is necessary here not to confound the Dublin "alcohol," which has the sp. gr. 0.810, with the U.S. "alcohol," which corresponds with the rectified spirit of the British Colleges.

This preparation is stronger, and less liable to spontaneous decomposition than the preceding; while its sensible and medical properties are nearly the same. A fluidounce of it, when evaporated, yields ten grains of a crimson coloured extract, which at first has the consistency of wax, but afterwards, when dried, is transparent. It is not easy to perceive the motive of the Dublin College for having two spirituous preparations of the acetate of iron. B.

FERRI CARBONAS PRÆCIPITATUS. *U.S.* FERRI SUBCARBONAS. *Lond.* CARBONAS FERRI PRÆCIPITATUS. *Ed.* FERRI CARBONAS. *Dub.* *Precipitated Carbonate of Iron.*

"Take of Sulphate of Iron *eight ounces;* Carbonate of Soda *six ounces;* Boiling Water *a gallon.* Dissolve the Sulphate of Iron and Carbonate of Soda severally in four pints of the Water; then mix the solutions, and set the mixture by that the powder may subside; lastly, having poured off the supernatant liquor, wash the Carbonate of Iron with hot water, wrap it in bibulous paper, and dry it with a gentle heat." *U.S.*, *Lond.*

The *Edinburgh College* directs *four ounces* of sulphate of iron, *five ounces* of subcarbonate of soda, and *ten pounds* of water; the *Dublin*, *twenty-five parts* of sulphate of iron, *twenty-six parts* of carbonate of soda, and *eight hundred parts* of water. The materials are then treated as in the above formula.

When the solutions of carbonate of soda and sulphate of iron are mixed together, a hydrated protocarbonate of iron of a green colour is thrown down, and sulphate of soda remains in solution. The equivalent quantities of the *crystallized* salts for mutual decomposition are 130.1 of the sulphate and 143.42 of the carbonate; so that six ounces of the alkaline carbonate are not sufficient to decompose eight ounces of the ferruginous salt, the proportions of the U.S. and London formulæ. The Edinburgh formula gives an excess of the carbonate of soda, while the Dublin proportions are not far from accurate. The precipitate is altered by drying, during which it absorbs oxygen, and loses more or less carbonic acid, whereby it becomes in part converted into hydrated peroxide of iron. When prepared with the greatest care, Mr. Phillips found it to contain 15 per cent. of carbonic acid; but ordinarily it contains about 5 per cent. of this acid; and if improperly made, not more than 1½ per cent. The precipitate always contains more carbonic acid, when the saline solutions for generating it are mixed at the temperature of 150°. As it does not readily subside, it is best separated by a filter, on which also the washing may be performed. Either of the fixed alkalies will answer to decompose the ferruginous sulphate; but the carbonate of soda is preferred, because it gives rise to the sulphate of soda, which, from its greater solubility, is washed away more readily than the sulphate of potassa. The precipitate should be dried at a heat not exceeding 200°; as above that temperature it would lose almost all its carbonic acid, and be reduced nearly to the state of peroxide.

Properties. Precipitated carbonate of iron is a reddish-brown powder of a slightly styptic taste; insoluble in water, but dissolving readily in acids with effervescence of carbonic acid. When imperfectly prepared it has a colour less inclining to brown, and is not so easily dissolved by acids, scarcely any effervescence being produced. It is incompatible with acids and acidulous salts. Its composition varies exceedingly, from the influence of slight differences in the mode of conducting the process for preparing it. Though called a carbonate, it is, strictly speaking, a mixture of hydrated peroxide of iron with the protocarbonate. Part of the protoxide of the precipitate, as first thrown down, is converted into hydrated peroxide in drying; and as carbonic acid will not combine to any extent with this oxide, nearly all the acid is given off which was united with the protoxide changed. It is so difficult to prevent the absorption of oxygen by the precipitate during exsiccation, that a perfect protocarbonate of iron can probably only be obtained in the humid way. (See *Mistura Ferri Composita.*) Still, however, with care, a considerable part of the protocarbonate will remain undecomposed; and there is reason to believe that the activity of the preparation will be in proportion to its amount.

Medical Properties and Uses. Precipitated carbonate of iron is one of our best chalybeates. Its virtues are those of a tonic, alterative, and emmenagogue, and it is employed for all the purposes to which the preparations of iron are generally applicable. It was recommended by Mr. Carmichael in cancer, and is said sometimes to prove useful. Mr. Hutchinson brought it into notice as a remedy for neuralgia; and an extensive experience with it in that disease has established its value. It is also useful in chorea. When prescribed as a tonic, the usual dose is from five to thirty grains three times a day, given in pill or powder, and frequently combined with aromatics and vegetable tonics. In neuralgia and chorea it is administered in doses of a drachm or more. We have given it in these diseases with success, and in doses of from one to two teaspoonfuls three times a day. No nicety need be observed in the dose; its only obvious effect in very large doses being a slight nausea and a sense of weight at the stomach. Its use gives the stools a black colour.

Off. Prep. Ferri Acetas, *Dub.;* Ferri et Potassæ Tartras, *U.S.;* Ferrum Ammoniatum, *Lond.;* Tinctura Ferri Muriatis, *U.S.*, *Lond.* B.

FERRI CARBONAS PRÆPARATUS. *U.S.* SUB-CARBONAS FERRI PRÆPARATUS. *Ed.* FERRI RUBIGO. *Dub.* *Prepared Carbonate of Iron. Rust of Iron.*

"Take of Iron Wire, cut into pieces, *any quantity.* Expose the Iron to the air, frequently moistening it with Water, till it is converted into rust. Rub this in an iron mortar, and prepare it in the manner directed for carbonate of lime." *U.S.*

"Moisten Purified Iron Filings frequently with Water, that they may be converted into rust, which is to be ground into an impalpable powder." *Ed.*

The *Dublin* process is almost identical with that of the U.S. Pharmacopœia.

Rust of iron, according to Berzelius, is a hydrated peroxide of iron, containing frequently a little protocarbonate. It is formed in consequence of the decomposition of the water, the oxygen of which converts the iron chiefly into peroxide, but partly also into protoxide, the latter of which becomes protocarbonate by absorbing carbonic acid from the atmosphere. Iron, in the form of wire, is, on account of its greater purity, preferable to the filings for forming this preparation. Though called a carbonate and a subcarbonate, it is hardly entitled to either appellation; as it sometimes contains no carbonate, and this salt, when present, is in variable quantity.

Properties, &c. Prepared carbonate of iron is in the form of a red powder of a slightly styptic taste. Its medical properties and dose are the same as those of the precipitated carbonate; but from its difficult solubility in acids it is far less eligible, and might, without detriment, be expunged from the officinal catalogue. (See *Ferri Carbonas Præcipitatus.*)

Off. Prep. Muriatis Ferri Liquor, *Dub.* B.

FERRI ET POTASSÆ TARTRAS. *U.S.* FERRUM TARTARIZATUM. *Lond.* TARTRAS POTASSÆ ET FERRI. *Ed.* FERRI TARTARUM. *Dub.* *Tartrate of Iron and Potassa.*

"Take of Precipitated Carbonate of Iron *half an ounce;* Supertartrate of Potassa *an ounce;* Distilled Water *a pint.* Boil them together over a gentle fire, in a glass vessel, for an hour, and filter the solution through paper. After it has become cold, again filter it, and evaporate by means of a water-bath, till the Tartrate of Iron and Potassa is entirely dried. Rub this into powder, and keep it in a well stopped bottle." *U.S.*

"Take of Iron *a pound;* Supertartrate of Potassa, in powder, *two pounds;* Distilled Water *five pints*, or *a sufficient quantity.* Rub together the Iron and Supertartrate of Potassa, and expose the mixture, in an open glass vessel, with a pint of Water, to the action of the air for twenty days, stirring it daily, and keeping it always moist by occasional additions of Distilled Water. Then boil it in four pints of Distilled Water for fifteen minutes, and filter. Evaporate the solution, by means of a water-bath, until the Tartarized Iron is perfectly dried. Rub this into powder, and preserve it in a well stopped bottle." *Lond.*

The *Edinburgh College* orders *one part* of purified iron filings, *two parts* of supertartrate, and *one part* of water, employs an earthen vessel, and exposes the mixture for fifteen days. The materials are then boiled for a short time with four times their weight of water, and the clear liquor poured off from the dregs. This is evaporated to dryness by means of a water-bath, and the dry mass reduced to powder and kept in close bottles. The *Dublin College* directs *one part* of fine iron wire, *four parts* of supertartrate, and *eight parts* or *a sufficient quantity* of distilled water, and treats the materials nearly as directed in the Edinburgh formula; the differences being that the iron during exposure is not to be entirely covered with water, that filtration is substituted for decantation, and that the product is not reduced to powder.

In these processes, the excess of acid in the supertartrate of potassa combines with protoxide of iron to form a prototartrate; which by the action of the air is converted into a pertartrate, and the resulting preparation is a double salt composed of pertartrate of iron and tartrate of potassa. In the U.S. process, which is that of the Dublin Pharmacopœia of 1807, the protoxide of iron is furnished by the precipitated carbonate; in those of the British Colleges, by the slow oxidation of metallic iron. As the precipitated carbonate contains only a small portion of protoxide, and the peroxide does not directly unite with the excess of acid of the cream of tartar, the U.S. process is liable to the objection of furnishing but a small product, an objection which caused the Dublin College to abandon it. Dr. Barker, in his Observations on the Dublin Pharmacopœia, states that the use of the precipitated carbonate gives rise to a large residue of undissolved cream of tartar and carbonate, and furnishes an *acid* product. When, however, metallic iron was used with the cream of tartar, mutual reaction gradually took place, and a dark brown *neutral* solution was obtained, which, when evaporated to dryness, furnished a mass of a resinous appearance, and completely soluble in water. When metallic iron is employed, it is protoxidized by the oxygen of the water, hydrogen being given off, and the protoxide formed immediately unites with the excess of acid in the cream of tartar. By the action of the air, the protoxide is converted into peroxide, and the prototartrate, consequently, into pertartrate. Fine iron wire is, perhaps, preferable to the filings, as these are apt to be impure. The only material difference between the British formulæ, is that the Dublin College uses only half as much iron as the other Colleges. The smaller quantity is probably quite sufficient, though no injury can result from the use of an excess of the metal.

Properties. Tartrate of iron and potassa is an olive-green powder, and, when properly prepared, has a sweetish and rather agreeable taste. If it contain an excess of acid from the imperfect saturation of the cream of tartar, its taste is disagreeable. When exposed to a damp atmosphere it becomes moist, and hence it requires to be preserved in close bottles. It is soluble in seven times its weight of water, forming a solution not liable to decomposition for a considerable time. It is not decomposed by the fixed alkalies or their carbonates in the cold, by ammonia, pure or carbonated, at any temperature, nor by ferrocyanate of potassa. It is incompatible with astringent vegetable infusions, the strong acids, hydrosulphuric acid gas, lime-water, and acetate of lead. According to Phillips it contains about 20 per cent. of peroxide of iron.

Dr. Ure has proposed the medical use of *prototartrate of iron.* He makes it by acting on clean iron filings, or bits of iron wire, with a solution of tartaric acid. The iron is protoxidized at the expense of the water, and uniting with the tartaric acid produces the prototartrate in the form of a powdery matter, which is obtained separate by diffusing it through the liquid, decanting, and washing on a filter. This salt is nearly white, pulverulent, and insoluble, and possesses a mild chalybeate taste.

Medical Properties and Uses. Tartrate of iron and potassa is one of the most agreeable preparations of iron, and may be given, generally, in cases in which chalybeates are indicated. From its slight taste when well prepared, and its ready solubility, it forms one of the best ferruginous preparations for exhibition to children. The dose is from ten grains to half a drachm, given in solution, or combined with an aromatic or bitter in the form of bolus. B.

VINUM FERRI. *Lond.* *Wine of Iron.*

"Take of Iron [wire or filings] *a drachm;* Supertartrate of Potassa, in powder, *six drachms;* Distilled Water *two pints*, or *a sufficient quantity;* Proof Spirit *twenty fluidounces.* Rub together the Iron and Supertartrate of Potassa, and expose them to the air for six weeks, in a shallow glass vessel, with *a fluidounce* of the Water, stirring daily with a spatula, and occasionally adding Distilled Water, so that the mixture may be always moist. Then dry it with a gentle heat, rub it into powder, and mix it with *thirty fluidounces* of the Distilled Water. Filter the solution, and after filtration add the Spirit." *Lond.*

The iron oxidized by the combined action of air and moisture, unites with the excess of acid of the supertartrate; and a double salt is ultimately formed, consisting of pertartrate of iron and tartrate of potassa, which, together with a portion of undecomposed supertartrate of potassa, is dissolved in the distilled water. The preparation is, therefore, a solution of tartrate of iron and potassa and of cream of tartar, in dilute spirit intended to represent wine. It contains, according to Mr. Phillips, only sixteen grains of peroxide of iron in the pint, considerably less than might be inferred to be present from the quantity of iron employed. The deficiency is ascribed by Mr. Phillips to three causes; 1. the incomplete oxidation of the metal, of which a portion remains unchanged; 2. the drying of the tartrate of iron and potassa, by which it is rendered partly insoluble; and 3. the precipitation of a part of the salt from its aqueous solution, upon the addition of the spirit. The preparation is absurdly called Wine of Iron, as no wine enters into its composition. So far as regards the chalybeate ingredient, it closely resembles the old wine of iron, made by macerating iron wire or filings previously oxidized by air and moisture, in some acidulous wine, containing supertartrate of potassa, which formed the double tartrate with the oxidized iron. But as the proportion of this salt is variable in different wines, the preparation was necessarily of unequal strength, and has been discarded both from the U.S. and Dublin Pharmacopœias, in which it formerly held a place.* The London preparation might also be discarded, as, though more uniform than the former, it is an exceedingly feeble chalybeate, and is in no respect superior to an extemporaneous solution of the tartrate of iron and potassa.

Medical Properties and Uses. The wine of iron is too stimulating in proportion to its tonic power to be employed except in cases of considerable general debility, united with enfeebled digestion. The dose is from half a fluidounce to two fluidounces, two or three times a day. W.

---

* The following is the formula for preparing Wine of Iron according to the former editions of the U.S. and Dublin Pharmacopœias. "Take of iron Wire, cut in pieces, *four ounces;* Wine [White Rhenish Wine, *Dub,*] *four pints.* Sprinkle the Wire with two pints of the Wine [a little of the Wine, *Dub.*] and expose it to the air till it is covered with rust, then add the rest of the Wine; macerate for ten days [digest for seven days, *Dub.*], with occasional agitation, and filter."

FERRI PHOSPHAS. *U. S. Phosphate of Iron.*

"Take of Sulphate of Iron *five ounces;* Phosphate of Soda *six ounces;* Water *a gallon.* Dissolve the Sulphate of Iron and Phosphate of Soda severally in four pints of the Water; then mix the solutions and set the mixture by that the powder may subside; lastly, having poured off the supernatant liquor, wash the Phosphate of Iron with hot water, and dry it with a gentle heat. *U. S.*

This preparation is the result of a double decomposition between the saline materials employed. The sulphuric acid combines with the soda and remains in solution as sulphate of soda; while the phosphoric acid, uniting with the protoxide of iron, falls as phosphate of iron. The amount of water directed is useful to ensure a prompt and complete mutual reaction of the two salts. If the ferruginous sulphate be a perfect protosulphate, the precipitate, as first thrown down, will be white; but it quickly absorbs oxygen and becomes bluish-white. It is in the form of an insoluble powder of a bright slate colour. According to Berzelius, it consists of a mixture of the protophosphate and perphosphate of iron.

Medical Properties and Uses. Phosphate of iron possesses the general properties of the ferruginous preparations, and has been given with advantage in amenorrhœa and some forms of dyspepsia. It was introduced into the U.S. Pharmacopœia, at the suggestion of Dr. Hewson of Philadelphia, who found it, after an extensive experience, to be a valuable chalybeate. The dose is from five to ten grains. B.

FERRI SULPHAS. *U. S., Lond. Dub.* SULPHAS FERRI. *Ed. Sulphate of Iron. Green Vitriol.*

"Take of Iron Wire, cut into pieces, Sulphuric Acid, each, *eight ounces;* Water *four pints.* To the Iron and Water, previously introduced into a glass vessel, add by degrees the Sulphuric Acid. When the effervescence shall have ceased, filter the solution through paper, and evaporate it so that crystals may form when it cools. Pour off the supernatant liquor, and dry the crystals upon bibulous paper." *U. S.*

The *London* process scarcely differs from the above, which was taken from it with slight alterations.

"Take of Purified Iron Filings *six ounces;* Sulphuric Acid *eight ounces;* Water *two pounds and a half.* Mix them, and when the effervescence is over, digest the mixture for some time on warm sand. Then filter the decanted liquor through paper, and after due evaporation, set it aside to crystallize." *Ed.*

"Take of Iron Wire *four parts;* Sulphuric Acid [Commercial?] *seven parts;* Water *sixty parts.* Dissolve the metal by the aid of heat, and filter the solution through paper. Lastly, after due evaporation, set aside the solution that crystals may form by slow refrigeration." *Dub.*

In these processes, a pure sulphate of the protoxide of iron is formed. Sulphuric acid, in a concentrated state, acts but imperfectly on iron; but when it is diluted, a vigorous action takes place, the oxygen of the water converts the metal into protoxide, with which the sulphuric acid unites, and hydrogen is evolved. The equivalent quantities for mutual reaction are 28 of iron to 49.1 of acid, which are the proportions taken by the Dublin College, and which were found to answer by Dr. Barker. In the other processes quoted, the iron is evidently in excess; but this is an error on the safe side, as it tends to secure the production of a perfect protosulphate, the portion of metal not dissolved being removed by the filtration. The quantity of water directed in the formulæ is sufficient to hold the salt in solution, and is necessary to enable the operator to comply with the direction to filter. A smaller quantity would be sufficient to form the salt, but would probably cause it to crystallize in mass, and thus interfere with the means of separating the impurities.

Sulphate of iron, under the name of *copperas*, is manufactured on a large scale, for the purposes of the arts, from the native sulphuret of iron, or pyrites, by roasting, oxidation by exposure to air and moisture, and lixiviation. The constituents of the mineral become sulphuric acid and protoxide of iron, which, by their union, form the salt in question. In this manner it is extensively manufactured at Stafford in Vermont, and at Cape Sable in Maryland. Sometimes, when the price of the product will justify it, our manufacturers of sulphuric acid make it from the unconcentrated acid, and scraps of old iron.

The sulphate of commerce is always impure, containing various foreign bodies, such as copper, zinc, alumina, magnesia, &c. Copper may be detected and separated by its deposition on an immersed polished plate of iron; but the other impurities are not easily got rid of. The commercial sulphate is, therefore, altogether unfit for medicinal employment, and should never be substituted by the apothecary for the officinal sulphate, which is made by the direct combination of its constituents, in order to ensure its purity.

Properties. Sulphate of iron is a bluish-green salt, having a disagreeable styptic taste, and an acid reaction. It crystallizes in oblique rhombic prisms, which, by exposure to the air, effloresce and absorb oxygen, and become, on the surface, first white, and afterwards yellow, passing gradually into the state of persulphate. It dissolves in twice its weight of cold, and in three-fourths of its weight of boiling water; but is insoluble in alcohol. When heated moderately it undergoes the watery fusion, and afterwards becomes dry and white; and at a red heat loses its acid and is converted into the red oxide of iron. (See *Sulphas Ferri Exsiccatus* and *Ferri Oxidum Rubrum.*) It is incompatible with the alkalies and their carbonates, soaps, lime-water, the muriates of lime and baryta, the borate and phosphate of soda, nitrate of silver, and the acetates of lead. It is also decomposed by astringent vegetable infusions, the tannin and gallic acid of which strike a black colour with the oxide of the sulphate; but how far this change may interfere with its medical activity is not well ascertained. It is composed of one equiv. of acid 40.1, one of protoxide 36, and six of water 54=130.1.

Medical Properties and Uses. Sulphate of iron is tonic and astringent. In large doses it is apt to produce nausea and vomiting, and griping of the bowels; and if its use be too long continued it injures the stomach. It has been recommended as a remedy for the scrofulous habit, conjoined with the extract of bark. In amenorrhœa with deficient action, it is frequently resorted to with advantage, either alone, or combined with the fetid and stimulant gums. It has also been given in diabetes. The dose is from one to five grains, in the form of pill. If given in solution, the water should be previously boiled to expel the air, which, if allowed to remain, would partially decompose the salt.

S., Lond., Dub.;* Pilulæ Ferri Compositæ, *U. S., Lond., Dub.;* Pilulæ Sulphatis Ferri Compositæ, *Ed.;* Sulphas Ferri Exsiccatus, *Ed.;* Ferri Acetatis Tinctura, *Dub.;* Tinctura Acetatis Ferri cum Alcohol, *Dub.*

B.

SULPHAS FERRI EXSICCATUS. *Ed.* *Dried Sulphate of Iron.*

"Take of Sulphate of Iron *any quantity.* Expose it to a moderate heat in an unglazed earthen vessel, until it becomes white and perfectly dry." *Ed.*

This process is merely intended to deprive the salt of its water of crystallization, which amounts to 41.78 per cent. The heat should not exceed 212°, otherwise the salt itself would suffer decomposition. Dried sulphate of iron may be used internally in the form of pill, and is employed pharmaceutically by the Edinburgh College for making *Acidum Aceticum Forte,* and *Oxidum Ferri Rubrum,* which are its only officinal preparations. B.

FERRI SULPHURETUM. *U.S., Dub.* SULPHURETUM FERRI. *Ed.* *Sulphuret of Iron.*

"Take of Iron Filings *four ounces* [Purified, three parts, *Ed.*]; Sulphur *two ounces* [Sublimed Sulphur one part, *Ed.*]. Mix, and expose them, in a covered crucible, to an obscure red heat, till they unite." *U. S.*

"Expose a rod of Iron to the strongest heat of a forge, until it becomes white hot; and upon taking it from the fire, instantly apply it to a roll of sulphur. Receive the Sulphuret of Iron in water, separate it from the sulphur, and, having dried it, keep it in a well stopped bottle." *Dub.*

Iron combines with sulphur in two principal proportions, forming a protosulphuret and a sesquisulphuret, which are proportional, in composition, to the protoxide and sesquioxide (peroxide) of this metal. It is the protosulphuret that is formed in the processes given. In the first, which is the easier of the two, the iron, in a divided form and mixed with the sulphur, is made to unite with it by the application of heat. At a particular temperature the mixture suddenly becomes incandescent, when the heat may be withdrawn. The operation may be performed in a Florence flask, one-third filled with the mixture, and heated with a chafing dish. When thus prepared, the sulphuret is apt to be mixed with sesquisulphuret and metallic iron. The Dublin process furnishes a purer product, but is not so easy of execution. On the application of the roll of sulphur to the heated iron, which should be at a white heat in order that the experiment may succeed well, the metal appears to become hotter, burns with scintillations in the vapour of the sulphur, and forms instantly a protosulphuret, which being comparatively fusible, melts into globules, and drops into the water, which serves to extinguish them. The sulphuret thus obtained is stated by Berzelius to contain an excess of iron. The process recommended by him as the best, consists in heating, in a close vessel, a mixture of sulphur and the cuttings of thin sheet iron. At a full red heat, the iron burns in the gaseous sulphur, and becomes covered with a crust of the sulphuret. The heat is then maintained at redness until all excess of sulphur has been driven off. Upon the cooling of the vessel the pieces of iron are bent to and fro, which causes the superficial sulphuret to scale off.

Properties, &c. Sulphuret of iron has a yellowish colour and the metallic lustre. When pure it furnishes a yellow powder, and dissolves in dilute sulphuric or muriatic acid without leaving a residue of sulphur, and with the production of hydrosulphuric acid gas (sulphuretted hydrogen), free from admixture of hydrogen. It consists of one equiv. of sulphur 16.1, and one of iron 28=44.1. This preparation is employed in the Pharmacopœias for the production exclusively of hydrosulphuric acid gas, a necessary ingredient or agent in several formulæ. It may be made to yield this gas by the action of diluted sulphuric acid. During the reaction water is decomposed; its hydrogen combines with the sulphur to form the hydrosulphuric acid, while the oxygen converts the iron into protoxide, with which the sulphuric acid combines. *Hydrosulphuric acid* is a colourless gas, having a smell like that of putrid eggs. Its sp. gr. is 1.1782. It reddens litmus and saturates bases, with which it forms salts called *hydrosulphates* or *hydrosulphurets*. It is generated in the processes for the following preparations:—Acidum Hydrocyanicum, *U. S.* Liquor Ammoniæ Hydrosulphatis, *U. S.*, *Ed.*, *Dub.* Potassii Iodidum, *U. S.*, *Dub.* B.

FERRUM AMMONIATUM. *U. S.*, *Lond.* MURIAS AMMONIÆ ET FERRI. *Ed.* *Ammoniated Iron.*

"Take of Red Oxide of Iron, Muriate of Ammonia, each, *a pound.* Mix them well together, and sublime quickly by the application of a strong heat; then rub the sublimed matter into powder." *U. S.*

"Take of Subcarbonate of Iron [Precipitated Carbonate], Muriatic Acid, Muriate of Ammonia, each, *a pound.* Pour the Muriatic Acid upon the Subcarbonate of Iron, and set the mixture aside till it ceases to effervesce. Filter the solution through paper, and evaporate it to dryness. Mix the residue thoroughly with the Muriate of Ammonia; then sublime immediately with a hot fire; lastly, rub the sublimed matter into powder." *Lond.*

"Take of Red Oxide of Iron, washed and dried, Muriate of Ammonia, each, *equal weights.* Mix them thoroughly, and sublime with a quick fire. Rub the sublimate into powder, and keep it in a well stopped phial." *Ed.*

In the U.S. and Edinburgh processes, which are essentially the same, a portion of the muriate of ammonia is decomposed, the ammonia escaping, and the muriatic acid reacting upon the peroxide of iron, so as to form water and the perchloride of iron, the latter of which is sublimed with the undecomposed portion of the muriate of ammonia. In the London process, the permuriate of iron is first obtained, and this is sublimed in connexion with muriate of ammonia, assuming probably during the operation the form of perchloride of iron. The quantity of carbonate of iron directed by the London College is unnecessarily large, as little more than half of it is dissolved.

A more convenient mode of preparing the Ammoniated Iron is that of the Paris Codex, which directs that three parts of muriate of ammonia and one of muriate of iron be dissolved together in a sufficient quantity of water, and the solution evaporated to dryness with a moderate heat. The muriate of iron of the Paris Codex, is the protomuriate formed by the action of muriatic acid upon metallic iron, but the permuriate resulting from the action of the same acid on the officinal precipitated carbonate or red oxide is preferable, as it is less liable to chemical change.

Properties. Ammoniated iron, as usually found in the shops, is in crystalline grains, of a yellow colour, a feeble odour, and a styptic saline taste. In this form it is probably a mixture of muriate of ammonia and permuriate of iron, obtained by evaporating a solution of these salts. (*Phillips.*) Procured by sublimation it has an orange colour, and probably contains iron in the state of perchloride. In either form it is highly soluble and deliquescent, and requires to be kept in well stopped bottles. The proportion of the perchloride of iron to the muriate of ammonia, in the sublimed preparation, is very variable, but usually small.

Medical Properties and Uses. This preparation unites aperient properties with those belonging to the chalybeates generally, and is said to have been used with advantage in amenorrhœa, epilepsy, scrofula, rickets, &c.; but it is at best uncertain, and is now very seldom prescribed. It was formerly employed under the names of *flores martiales*, and *ens martis*. From four to twelve grains may be given in the form of pill, electuary, or solution, several times a day.

Off. Prep. Tinctura Ferri Ammoniati, *Lond.* W.

TINCTURA FERRI AMMONIATI. *Lond.* *Tincture of Ammoniated Iron.*

"Take of Ammoniated Iron *four ounces;* Proof Spirit *a pint.* Macerate and filter." *Lond.*

This is simply a solution of the preceding preparation in diluted alcohol. It is feeble and uncertain as a chalybeate, and has no particular claims to attention. W.

TINCTURA FERRI MURIATIS. *U.S.*, *Lond.* TINCTURA MURIATIS FERRI. *Ed.* MURIATIS FERRI LIQUOR. *Dub.* *Tincture of Muriate of Iron.*

"Take of Precipitated Carbonate of Iron *half a pound;* Muriatic Acid *a pint;* Alcohol *three pints.* Pour the Acid upon the Carbonate of Iron, in a glass vessel, and shake the mixture occasionally for three days; then set it by that the dregs, if there be any, may subside; lastly, pour off the liquor, and to this add the Alcohol." *U.S.*

The process of the *London College* is the original of the above, and differs from it only in the nomenclature.

"Take of Purified Black Oxide of Iron, in powder, *three ounces;* Muriatic Acid about *ten ounces*, or as much as may be sufficient to dissolve the Oxide. Digest with a gentle heat, and when the powder is dissolved, add as much Alcohol as will make the whole quantity of liquor amount to two pounds and a half." *Ed.*

"Take of Rust of Iron *one part;* Muriatic Acid, Rectified Spirit, each, *six parts.* Pour the Acid upon the Rust in a glass vessel, and shake the mixture occasionally for three days. Then set it by that the dregs may subside, and pour off the clear liquor. Evaporate this slowly to one-third, and when it is cold add the Spirit." *Dub.*

The precipitated carbonate of iron of the shops consists of the peroxide of iron, mixed with a variable, but always small proportion of the protocarbonate. When acted on by muriatic acid, as in the U.S. and London processes, it is dissolved with effervescence, in consequence of the escape of carbonic acid; and a solution of the permuriate of iron, with a little protomuriate, is obtained. When the muriatic acid employed is of the officinal strength (sp. gr. 1.160), it dissolves nearly all the precipitated carbonate, leaving behind, according to Mr. Phillips, less than one scruple, including accidental impurities. A reaction appears to take place between the muriatic acid and the alcohol, as the preparation has a decided ethereal odour. On exposure, the protoxide of iron of the protomuriate is converted by the absorption of oxygen into peroxide, which, requiring a larger proportion of acid than the former for its saturation, is partly precipitated. A slight excess of acid would, therefore, not be amiss, as the peroxide would thus be held in solution, and the preparation be of more uniform strength. The black oxide of iron, employed by the Edinburgh College instead of the precipitated carbonate, yields with the muriatic acid a larger proportion of the protomuriate; and the solution is, therefore, still more apt, upon exposure, to deposite peroxide, than that of the U.S. and London Pharmacopœias. The Dublin process is liable to the objection of a great waste of acid, of which much more is employed than is necessary to dissolve the quantity of rust of iron directed, the excess being driven off by heat. It is important that the apothecary should employ muriatic acid of the officinal specific gravity, as otherwise his preparation will be of uncertain strength. A want of attention to this circumstance is probably the cause that the tincture, as found in the shops, is very unequal. Of four specimens examined by Mr. Phillips, one contained in half a fluidounce 20 grains of peroxide of iron, another 12.1 grains, a third 11.3 grains, and the fourth only 9.3 grains. A specimen prepared by himself, precisely according to the directions of the London College, had the sp. gr. 0.994, and contained in half a fluidounce 16.8 grains of peroxide.

Properties. The tincture of muriate of iron is of a reddish-brown, somewhat yellowish colour, a sour and very styptic taste, and an odour resembling that of muriatic ether. The permuriate of iron, which is its chief constituent, is a deliquescent salt, of a dark orange colour, scarcely crystallizable, and consisting of one equiv. of peroxide of iron 80, and three equiv. of muriatic acid 109.26=189.26. The tincture is decomposed by the alkalies, alkaline earths, and their carbonates, astringent vegetable infusions, and the mucilage of gum Arabic, which are, therefore, incompatible with it in prescriptions.

Medical Properties and Uses. This is one of the most active and certain preparations of iron, usually acceptable to the stomach, and much employed for all the purposes to which the chalybeates generally are applied. It is particularly recommended as a tonic in scrofula, in which it is often given, conjointly with the solution of muriate of lime, or muriate of baryta. It has been employed also in gleets, and is said to be useful in dysury dependent on spasmodic stricture of the urethra, in the dose of ten drops repeated every ten minutes, till some effect is experienced. In hemorrhages from the uterus, kidneys, and bladder, it is thought to act advantageously, but should be confined to those of a passive character, or employed only after sufficient depletion. Externally it has sometimes proved useful in the destruction of venereal warts, and as a styptic in cancerous and fungous ulcers. The dose is from ten to thirty minims, which may be gradually increased to one, or even two fluidrachms, two or three times a day. It is given diluted with water. W.

LIQUOR FERRI ALKALINI. *Lond.* *Solution of Alkaline Iron.*

"Take of Iron *two drachms and a half;* Nitric Acid *two fluidounces;* Distilled Water *six fluidounces;* Solution of Subcarbonate of Potassa *six fluidounces.* Pour the Acid and Water, previously mixed together, upon the Iron; then, after the cessation of effervescence, pour off the acid solution. Add this gradually and at intervals to the Solution of Subcarbonate of Potassa, occasionally stirring, until the liquor, having assumed a red-brown colour, ceases to effervesce. Lastly, set it aside for six hours, and pour off the solution." *Lond.*

In the first step of this process, the iron, by the decomposition of a portion of the nitric acid, is converted into the peroxide, which unites with a part of the undecomposed acid to form the pernitrate of iron, while nitric oxide gas escapes with effervescence, assuming the form of red fumes on contact with the air. A reddish-brown solution of pernitrate of iron is thus obtained, with a considerable excess of nitric acid. When this is added to the solution of carbonate of potassa, the free nitric acid, as well as that of the salt of iron, combines with the potassa to form nitre, carbonic acid escapes with effervescence, and the peroxide of iron is precipitated for a moment, to be again dissolved by the excess of the alkaline carbonate. From the liquor thus prepared, when allowed to stand, most of the nitrate of potassa separates in a spongy mass of crystals, from which the liquor is poured off.

Properties. This solution has a deep red colour, and an alkaline styptic, saline taste. It contains nitrate of potassa, carbonate of potassa, and peroxide of iron; but in what precise mode these are combined has not been ascertained. Upon the addition of water it lets fall the peroxide of iron; and alcohol separates all the solid ingredients. So loosely are its constituents held together, that, according to Dr. Paris, it cannot be administered in any form without undergoing decomposition. It is an inelegant preparation, without any superiority as a chalybeate to counterbalance its inconveniences; and might very properly be discarded from the London Pharmacopœia.

Medical Properties. The solution of alkaline iron, or, as it might be more appropriately called, the alkaline solution of iron, has the general properties of the chalybeates united with those of an antacid. It is, we believe, never employed in this country. The dose is from thirty minims to a fluidrachm. W.

* * *

GUMMI-RESINÆ.

Gum-resins.

These are concrete natural juices of plants, obtained by spontaneous exudation or incision, and consisting of gum and resin, associated for the most part with more or less essential oil, and frequently with other substances, such as extractive, bassorin, starch, wax, and various salts. The gum and resin are essential ingredients, but exist in very different proportions in the different varieties. All the gum-resins are partially soluble in alcohol and in water, but completely so in neither of these liquids. Diluted alcohol, on the contrary, dissolves them almost entirely, especially if assisted by heat. With water they form an opaque emulsion; the resin, essential oil, and other insoluble constituents being held in suspension by the dissolved gum.

The *London College* gives the following directions in relation to the gum-resins.*

"Those Gum-resins are to be preferred, which may be chosen so perfect as not to require purification. But if they do not appear to be sufficiently pure, boil them in water until they soften, and express them through a hempen cloth; then set them by that the resinous part may subside. Pour off the supernatant liquid, and evaporate it by means of a water-bath, adding, towards the end of the process, the resinous portion, so as to incorporate it with the gum.

"The Gum-resins which melt easily, may be purified by putting them into an ox bladder, and holding them in boiling water, until they become so soft as to be capable of being separated from their impurities by expression through a hempen cloth."

The first of these processes is applicable to the gum-resins only when they are intended for external use; for the essential oil, upon which their medicinal virtues often in great measure depend, is more or less dissipated by the heat employed. The latter process is preferable whenever practicable, as it affects less the character of the medicine; but several of the gum-resins, such as assafetida and ammoniac, are not sufficiently fusible at the temperature of boiling water to admit of being strained with facility. It is always best to select those intended for internal exhibition, of such a quality as not to require purification. As they are usually brittle and pulverizable when very cold, they may be freed from the coarser impurities by powdering them in the winter season, and sifting the powder, which afterwards agglutinates with warmth. This plan is recommended by Mr. Brande, in relation to assafetida, ammoniac, and galbanum. The French pharmaceutists purify the gum-resins by dissolving them in diluted alcohol, filtering and evaporating the solution. This process, though liable in a still greater degree than that of the London College to the objection of diminishing the virtues of the medicine by driving off the essential oil, has the advantage of completely separating all insoluble substances, however minutely divided, such as fine sand or other earth, which might pass through the pores of a hempen strainer. W.

HYDRARGYRUM.

Preparations of Mercury.

HYDRARGYRUM PURIFICATUM. *U.S., Lond., Dub.* HYDRARGYRUS PURIFICATUS. *Ed. Purified Mercury.*

"Take of Mercury *any quantity*. Pour it into an iron retort, and having applied heat, distil the Purified Mercury." *U. S., Lond.*

"Take of Mercury *six parts;* Iron Filings *one part*. Rub them together, and distil from an iron vessel." *Ed.*

"Take of Mercury *six parts*. Draw off *four parts* by slow distillation." *Dub.*

The mercury of commerce is usuaally very pure; but occasionally it contains foreign metals, such as lead, tin, zinc, and bismuth, and hence the Pharmacopœias direct its purification. Mercury being much more volatile than the contaminating metals, rises first in distillation, while they are left behind. But it is necessary to avoid pushing the distillation too far; for in that event, some of the foreign metals, particularly bismuth, are apt to be carried over. The Dublin Pharmacopœia, on account of this danger, directs only two-thirds of the mercury to be drawn over; while the other Pharmacopœias distil the whole. The iron filings directed by the Edinburgh College appear to be useless, as they have no affinity for the contaminating metals. Considering the difficulty of purifying mercury by distillation, it is better for the manufacturing chemist to purchase pure samples of the metal, which may be always had in the market, and thus supersede the necessity of this process.

Properties, &c. Mercury is known to be pure when it is bright and perfectly mobile. Its freedom from foreign metals may be ascertained by the negative indications of the tests mentioned under *Hydrargyrum*. Purified mercury is used in all the preparations of mercury requiring the metal, except the mercurial plaster of our Pharmacopœia, in which the unpurified metal is employed. B.

HYDRARGYRI ACETAS. *Dub.* ACETAS HYDRARGYRI. *Ed. Acetate of Mercury.*

"Take of Purified Mercury, Acetate of Potassa, each, *nine parts;* Diluted Nitric Acid *eleven parts;* boiling Distilled Water *one hundred parts;* Distilled Vinegar *a sufficient quantity*. Add the Nitric Acid to the Mercury, and when the effervescence shall have ceased, digest the mixture, so as to dissolve the metal. Dissolve the Acetate of Potassa in the Water, and add Distilled Vinegar until acidity predominates in the solution. To this, boiling hot, add the solution of the Mercury in the Nitric Acid, and strain the mixture quickly through a double linen cloth; then let it cool that crystals may form. Wash these with cold Distilled Water, and dry them on paper with a very gentle heat. In every step of this process, glass vessels are to be used." *Dub.*

The *Edinburgh College* orders *three ounces* of purified mercury, *four ounces and a half* of diluted nitrous acid, or a little more than sufficient to dissolve the mercury, *three ounces* of acetate of potassa, and *eight pounds* of boiling water, and treats the materials in a similar manner to the above, merely omitting to acidulate with distilled vinegar, and to strain through linen.

The object of these processes is to obtain an acetate of the protoxide of mercury. By the solution of mercury in diluted nitric acid, in the proportions indicated, a protonitrate is formed; and this, when added to the boiling solution of acetate of potassa, causes a double decomposition, resulting in the formation of nitrate of potassa, which remains in solution, and protacetate of mercury, which precipitates in crystals as the solution cools. The nitric acid is used diluted in order to avoid peroxidizing the metal; and for the same reason heat is not applied until the action of the acid has ceased in the cold, and then only moderately. Notwithstanding every precaution, it is very difficult to get a perfect protonitrate of mercury; and as water throws down a yellow subnitrate from the pernitrate if the solutions be neutral, the Dublin College orders the solution of the acetate of potassa to be acidulated with distilled vinegar, which effectually prevents this precipitation. The same object is gained in the Edinburgh formula, by using a slight excess of nitric acid for dissolving the mercury. The straining of the solution while hot, as directed by the Dublin College, is intended to separate any subnitrate which may be accidentally formed. As the crystals of the acetate of mercury may be contaminated with a little pernitrate, which is rendered yellow by the action of water, some authorities recommend that the washing should be performed with water acidulated with a little distilled vinegar. The drying of the crystals is an operation which requires great care, as a slight heat is sufficient to decompose them. On this account it has been proposed to dry them by compression between the folds of bibulous paper.

Properties, &c. Acetate of mercury is a white salt, in the form of thin elastic scales of a silvery lustre. Its taste is very disagreeable, but less so than that of most of the other soluble salts of mercury. Air has no effect on it, but it contracts a brown tinge by exposure to light. It is insoluble in alcohol, but dissolves readily, with partial decomposition, in boiling water, from which, being only sparingly soluble in cold water, it precipitates in crystals on cooling. When a perfect protacetate, alkalies throw down from its solution a black precipitate of protoxide; but if it be contaminated with peracetate, the same reagents cause a yellowish precipitate. It consists of one equiv. of acetic acid 51.48, one of protoxide of mercury 210, and four of water 36=297.48.

Medical Properties. Acetate of mercury was introduced into regular practice in consequence of its having been ascertained to be the active ingredient in Keyser's pills, which were at one time esteemed to be a mild and safe antisyphilitic remedy, and the mode of preparing which was purchased and made public by the French government. These pills, however, are very unequal in their operation; and it is the opinion of M. Garot, that their occasional violence is attributable to their containing the peracetate instead of the protacetate of mercury. The officinal acetate is intended to be a protacetate; but even in this state it possesses no peculiar powers which give it advantages over other mercurials in the treatment of syphilis; and it is at present very little used. The dose is a grain, given in the form of pill, twice a day. It is occasionally used as an external application to cutaneous eruptions, in the proportion of a grain dissolved in a fluidounce of rose-water. B.

HYDRARGYRI CHLORIDUM CORROSIVUM. *U.S.* HYDRARGYRI OXYMURIAS. *Lond.* MURIAS HYDRARGYRI CORROSIVUS. *Ed.* HYDRARGYRI MURIAS CORROSIVUM. *Dub.* *Corrosive Chloride of Mercury. Corrosive Sublimate.*

"Take of Purified Mercury *two pounds;* Sulphuric Acid *thirty ounces;* Chloride of Sodium *four pounds.* Boil the Mercury with the Sulphuric Acid, in a glass vessel, until the sulphate of mercury is left dry. Rub this, when cold, with the Chloride of Sodium, in an earthenware mortar; then sublime in a glass cucurbit, with a gradually increasing heat." *U.S.*

The London and Edinburgh processes agree with the above in the proportions of the materials employed; and only differ from it slightly in phraseology.

"Take of Persulphate of Mercury *five parts;* dried Muriate of Soda *two parts.* Rub them well together in an earthenware mortar, so as to reduce them to a very fine powder. Then, with a heat gradually raised, sublime the Corrosive Muriate of Mercury into a proper receiver." *Dub.*

In order to understand the above processes, which are the same in principle, it is necessary to premise, that corrosive sublimate is a bi-chloride of mercury, consisting of two equiv. of chlorine and one of mercury. By boiling sulphuric acid on mercury to dryness, as directed in the first process, a white salt is formed, which is a bisulphate of the peroxide of mercury. (See *Hydrargyri Persulphas*, Dub.) When this is mixed with chloride of sodium (common salt), and the mixture exposed to a subliming heat, a mutual decomposition takes place; the chlorine of the common salt combines with the mercury, and sublimes as bichloride of mercury, while the sodium, oxygen of the peroxide of mercury, and sulphuric acid unite to form sulphate of soda, which remains behind. The quantities for mutual decomposition are two equiv. of chloride of sodium 117.44, consisting of two equiv. of chlorine 70.84, and two equiv. of sodium 46.6; and one equiv. of the bisulphate of the peroxide of mercury, consisting of one equiv. of mercury 202, two equiv. of oxygen 16, and two equiv. of sulphuric acid 80.2. The two equiv. of chlorine combine with the one equiv. of mercury, to form one equiv. of corrosive sublimate 272.84, and the two equiv. severally, of sodium, oxygen, and sulphuric acid, by their union, form two equiv. of dry sulphate of soda 142.8. In the U.S. formula, quoted above, a large excess of common salt is directed. It may be desirable to have a slight excess of the salt; but so large a redundancy has no power of increasing the product of corrosive sublimate, as was ascertained experimentally by Dr. Barker of Dublin.

The Dublin formula for corrosive sublimate is peculiar in ordering the bisulphate of the peroxide of mercury ready formed, instead of preparing it as the first step of the process, as is done in the processes of the other Pharmacopœias.

As the British Colleges adopt the old theory of the nature of common salt and corrosive sublimate, namely that they are *muriates*, it may be well to explain the formation of the latter on that theory. According to the old theory, the reaction takes place between two equiv. of muriate of soda, and one equiv. of bisulphate of mercury. The two equiv. of soda combine with the two equiv. of sulphuric acid to form two equiv. of sulphate of soda; while the two equiv. of dry muriatic acid sublime in union with the one equiv. of peroxide of mercury, to form the *bi*muriate of the *per*oxide—the corrosive muriate of the British Pharmacopœias. Thus, while the new theory makes corrosive sublimate a bichloride of mercury, the old one considers it a bipermuriate. According to both views, the compound has the same equivalent number, and consists of one equiv. of mercury, combined with the same quantity of matter. This matter is considered, according to the new theory, to consist of two equiv. of a simple body, called chlorine, but according to the old, of two equiv. of an imaginary body called *dry* muriatic acid, and two equiv. of oxygen.

Considering the fact that the chloridic theory is now fully established, and that the old theory is not advocated by a single chemist of note, it is remarkable that the British Colleges have still adhered to the latter, and misnamed their chlorides of mercury. The U.S. Convention, in the revision of our Pharmacopœia, in 1830, avoided this error, by adopting a correct nomenclature for these compounds. In the instance of the substance under consideration, it is correctly called a *chloride*, while its deleterious nature is sufficiently marked by the adjunct "*corrosivum*," an epithet which has served to distinguish it from an early period.

Preparation on the Large Scale, &c. According to Mr. Brande, the following proportions are employed at Apothecaries' Hall, London:—"50 lbs. of mercury are boiled to dryness with 70 lbs. of sulphuric acid: 73 lbs. of bipersulphate of mercury are thus formed, which, being perfectly mixed with 120 lbs. of common salt, and sublimed, yield from 63 to 65 lbs. of corrosive sublimate." It is sometimes useful to a physician to know how to make a small portion of corrosive sublimate on an emergency. This may be done by dissolving peroxide of mercury (red precipitate) in muriatic acid, evaporating the solution to dryness, dissolving the dry mass in water, and crystallizing. At first a bimuriate of the peroxide is formed in solution, which, by crystallizing, loses the elements of water, and becomes the bichloride.

Properties. Corrosive chloride of mercury, as obtained by sublimation, is in the form of white, semitransparent, ponderous masses, of the sp. gr. 5.2, permanent in the air, and possessing an exceedingly acrid, styptic, and durable taste. It dissolves in sixteen parts of cold water, and in three of boiling water. A boiling saturated solution, upon cooling, lets it fall in a confused mass of crystals. By solution, it may be considered as converted, by the decomposition of two equiv. of water, into a bimuriate of the peroxide. It is soluble also in two and a third parts of cold alcohol, in about its own weight of boiling alcohol, and in three parts of ether. Sulphuric, nitric, and muriatic acids dissolve it without alteration. When heated it melts, and readily sublimes in dense, white, acrid vapours, which condense, on cool surfaces, in white, shining needles. Its aqueous solution renders green the syrup of violets, and is precipitated brick-red, becoming yellow, by the fixed alkalies and alkaline earths, and white by ammonia. (See *Hydrargyrum Ammoniatum.*) The former precipitate is a hydrated peroxide of mercury, and is formed in the process for preparing the *aqua phagedænica* of old pharmacy, which is obtained by dissolving a drachm of corrosive sublimate in a pint of lime-water. Corrosive sublimate forms with muriate of ammonia and chloride of sodium, compounds which are more soluble than the uncombined mercurial salt. It is on this account that aqueous solutions of sal ammoniac, or of common salt, dissolve much more corrosive sublimate than simple water. The combination of corrosive sublimate with muriate of ammonia was formerly called *sal alembroth*, or *salt of wisdom*.

Corrosive sublimate has the property of retarding putrefaction in a remarkable degree. Animal matters, immersed in its solution, shrink, acquire firmness, assume a white colour, and become imputrescible. It is on account of this property that it is often usefully resorted to for the preservation of anatomical preparations.

Tests of Purity and Incompatibles. Pure corrosive chloride of mercury sublimes, when heated, without residue; and consequently, if a portion of a sample should not evaporate entirely, the presence of some impurity is proved. If calomel be present, it may be detected by its insolubility in water. Corrosive sublimate is incompatible with many of the metals, with the alkalies and their carbonates, with soap, lime-water, tartar emetic, nitrate of silver, the acetates of lead, the sulphurets of potassa and soda, and all the hydrosulphates. It is also decomposed by many vegetable and some animal substances, and in most cases is converted by them into protochloride of mercury or calomel. According to Dr. Thomson (London Dispensatory), it produces precipitates in infusions or decoctions of the following vegetable substances;—chamomile, horse-radish, columbo, catechu, cinchona, rhubarb, senna, simaruba, and oak-bark. B.

Medical Properties and Uses. Corrosive sublimate is the most powerful of the mercurial preparations, operating quickly on the system, and, if not properly regulated, producing very violent effects. It is less apt to salivate than most other mercurials. In minute doses properly repeated, it exerts its peculiar influence without any obvious alteration of the vital functions, except, perhaps, a slight increase in the frequency of the pulse, and in the secretions from the skin and kidneys. Sometimes, however, it purges; but this effect may be obviated by combining it with a little opium. In larger doses it occasions nausea, vomiting, griping pain in the bowels, diarrhœa, and other symptoms of gastric and intestinal irritation; and in still larger quantities produces all the effects of a violent corrosive poison. It has long been used as a remedy in syphilis, in all stages of which it is highly recommended by some authors. It is said to remove the symptoms more speedily than other mercurials, while its action is less unpleasant, as the mouth is less liable to be made sore. For the latter reason it is much employed by empyrics, and is an ingredient in almost all those nostrums which have at various periods gained a temporary popularity as antivenereals. But while it is extolled by some authors, others, among whom is Mr. Pearson of London, deny its extraordinary merits, and maintain that, though occasionally useful in arresting the progress of the complaint, particularly in the secondary stage, it does not produce permanent cures, and, in the primary stage, often fails altogether. The general opinion at present is in favour of its employment in secondary syphilis, and there can be no doubt that it occasionally does much good. It is also used advantageously in cutaneous diseases of a leprous character, and in obstinate chronic rheumatism. It is usually associated with alterative or diaphoretic medicines, such as the antimonials, and the compound decoction or syrup of sarsaparilla; and, in order to obviate the irritation it is apt to produce, it may often be advantageously united with opium, or extract of hemlock. There is no doubt that many of the substances in connexion with which it is employed, alter its chemical condition; but it does not follow that even in its altered state it may not be very useful as a remedy.

As an external remedy, corrosive sublimate is stimulant and escharotic. A very weak solution in water, containing from an eighth to half a grain in the fluidounce, is employed as an injection in gleet, as a gargle in venereal sorethroat, and as acollyrium in chronic venereal ophthalmia. A stronger solution, containing one or two grains in the fluidounce, is a very efficacious wash in lepra, and other scaly cutaneous eruptions. Dissolved in water, in the proportion of five or ten grains to the fluidounce, it may be used with much benefit in venereal ulcers of the throat, to which it should be applied by means of a camel's hair pencil. With lime-water it forms the *aqua phagedænica* of the older writers, employed as a wash in ill-conditioned ulcers. The powdered chloride has been used as an escharotic; but is, in general, inferior to nitrate of silver or caustic potassa. In *onychia maligna*, however, it is employed with great advantage, mixed with an equal weight of sulphate of zinc, and sprinkled thickly upon the surface of the ulcer, which is then to be covered with a pledget of lint saturated with tincture of myrrh. The whole diseased surface is thus removed, and the necessity of resorting to the knife is avoided. This practice was first introduced, we believe, by Dr. Perkins of Philadelphia, and is highly recommended by Dr. Physick. We have employed it in several instances with complete success.

The dose of corrosive sublimate is from an eighth to a quarter of a grain, repeated three or four times a day, and given in pill, or dissolved in water or spirit. The pill, which is the preferable form, is usually prepared with crumb of bread, and care should be taken that the medicine be equally diffused through the pilular mass, before it is divided. Mucilaginous drinks are usually given to obviate the irritating effects of the medicine.

Toxicological Properties. Swallowed in poisonous doses, it produces a sense of burning heat in the throat, excruciating pain in the stomach and bowels, excessive thirst, anxiety, nausea and frequent retching with vomiting of bloody mucus, diarrhœa and sometimes bloody stools, small and frequent pulse, cold sweats, general debility, difficult respiration, cramps in the extremities, faintings, insensibility, convulsions, and death. The mucous membrane of the stomach exhibits on dissection all the signs which mark the action of a violent corrosive poison. In the treatment of a case of poisoning by corrosive sublimate, Orfila recommends the free use of the whites of eggs beat up with water. The albumen of the eggs decomposes the corrosive sublimate; and the liquid by its bulk dilutes the poison, and distends the stomach so as to produce vomiting. The insoluble substance formed by the reaction of albumen upon corrosive sublimate, which has usually been thought to consist of albumen and calomel, has been proved by Rose to be a compouud of albumen and oxide of mercury. (*Turner.*) If eggs cannot be procured, wheat flour mixed with water may be substituted, gluten having, according to M. Taddei, the same effect as albumen. Should neither of these antidotes be at hand, mucilaginous drinks should be largely administered; and in any event, the patient should be made to drink copiously, so long as vomiting continues, or till the symptoms are relieved. Should he be unable to vomit, the stomach should be washed out by means of the stomach pump. The consecutive inflammation should be treated with general or local bleeding, fomentations, and cooling mucilaginous drinks, and the attendant nervous symptoms be alleviated by opiates. W.

Tests for Corrosive Sublimate. On account of the extreme virulence of this chloride as a poison, the reagents by which it may be detected form a subject of inquiry of the utmost importance, as connected with medico-legal investigations. The best tests for it, according to Dr. Christison, are hydrosulphuric acid gas (sulphuretted hydrogen), hydriodate of potassa, protochloride of tin, and nitrate of silver. A stream of hydrosulphuric acid transmitted through a solution of corrosive sublimate, produces a black precipitate of sulphuret of mercury, and acts as a very delicate test. A solution of hydriodate of potassa produces a very characteristic pale scarlet precipitate of biniodide of mercury. Protochloride of tin causes at first a white, and afterwards a grayish-black precipitate, and, as a test, is not liable to any fallacy. Nitrate of silver causes a heavy white precipitate of chloride of silver, which darkens by exposure to light. This test detects the chlorine of the corrosive sublimate, and serves to determine, after the other reagents have detected the mercury, by what means the metal is held in solution. In addition to these tests, the following may be mentioned. *Lime-water* throws down a yellow precipitate of peroxide. *Ammonia* produces a fine white flocculent precipitate. *Ferrocyanate of potassa* gives rise to a white precipitate, becoming slowly yellowish, and at length a pale blue. *A bright plate of copper* immersed in the solution is instantly tarnished, and after the lapse of half an hour becomes covered with a grayish-white powder. Lastly, *a polished piece of gold*, moistened with the mercurial solution, and touched, through the liquid, with a piece of iron, becomes silvery white. This test, which was proposed by Mr. Sylvester and simplified by Dr. Paris, is conveniently applied by moistening a gold ring with the suspected solution, and touching the ring through the moistened spot with the point of a penknife. The object of the iron is to form with the gold a simple galvanic circle, which enables the latter metal to precipitate the mercury on its surface.

By the combined indications of the foregoing tests, corrosive sublimate may be infallibly detected; unless it exists in very minute quantity, associated with organic substances, by which its presence is often greatly obscured. When it exists in organic mixtures, made by boiling the contents or substance of the stomach in distilled water, Dr. Christison recommends that a preliminary trial be made, with the protochloride of tin, on a small portion filtered for the purpose. If this causes a grayish-black colour, he shakes the mixture, as recommended by Orfila, with a fourth of its bulk of sulphuric ether, which dissolves the chloride and rises to the surface. The ethereal solution is then evaporated to dryness, and the dry salt obtained is dissolved in hot water, whereby a pure solution is procured, in which the corrosive sublimate may be readily detected by the ordinary tests. If the trial test should produce a light gray colour, the chloride is indicated in still less quantity, and Dr. Christison recommends to proceed in the following manner. Treat the unfiltered mixture with protochloride of tin, as long as any precipitate is formed, which will have a slate-gray colour. Collect, wash, and drain it on a filter, and, having removed it without being dried, boil it, in a glass flask, in a moderately strong solution of caustic potassa, until all the lumps disappear. The alkali will dissolve all animal and vegetable matter, and on allowing the solution to remain at rest, a heavy grayish-black powder will subside, which consists chiefly of metallic mercury, and in which small globules of the metal may sometimes be discovered, either by the naked eye, or by the aid of a magnifier. For further details, see *Christison on Poisons*, 2d. edit. Edinburgh, 1832.

Off. Prep. Hydrargyrum Ammoniatum, *U. S.*, *Lond.*, *Dub.;* Liquor Hydrargyri Oxymuriatis, *Lond.;* Sub-Murias Hydrargyri Mitis. *Ed.* B.

LIQUOR HYDRARGYRI OXYMURIATIS. *Lond.* *Solution of Oxymuriate of Mercury.*

"Take of Oxymuriate of Mercury [Corrosive Sublimate] *eight grains;* Distilled Water *fifteen fluidounces;* Rectified Spirit *a fluidounce.* Dissolve the Oxymuriate of Mercury in the Distilled Water, and add the Spirit to it." *Lond.*

This solution was intended to facilitate the dispensing of corrosive sublimate in small doses. On exposure to light it suffers decomposition, calomel being deposited, and free muriatic and chloric acids formed in the water. According to Dr. Davy, the decomposition is accelerated by the addition of a small quantity of alcohol; so that the formula of the London College is not judicious. Mr. Brande states, that the decomposition is entirely prevented by the presence of muriate of ammonia, or common salt, and recommends the addition of eight grains of the former to the officinal solution. The dose of the solution, of which a fluidounce contains half a grain of corrosive sublimate, is from one to four fluidrachms taken in flaxseed tea. W.

HYDRARGYRI CHLORIDUM MITE. *U.S.* HYDRARGYRI SUBMURIAS. *Lond.* SUB-MURIAS HYDRARGYRI MITIS, sive CALOMELAS. *Ed.* CALOMELAS SUBLIMATUM. *Dub.* *Mild Chloride of Mercury. Submuriate of Mercury. Calomel.*

"Take of Purified Mercury *four pounds;* Sulphuric Acid, *thirty ounces;* Chloride of Sodium *a pound and a half.* Boil two pounds of the Mercury with the Sulphuric Acid, in a glass vessel, till the sulphate of mercury is left dry. Rub this, when cold, with the remainder of the Mercury, in an earthenware mortar, so that they may be thoroughly mixed. Then add the Chloride of Sodium, and rub it with the other ingredients, till all the globules disappear; afterwards sublime. Reduce the sublimed matter to a very fine powder, pass it through a sieve, and wash it frequently with boiling distilled water, till this affords no precipitate upon the addition of water of ammonia. Lastly, prepare the powder in the manner directed for the carbonate of lime." *U. S.*

The *London* formula is the same with the above, except that the powdered sublimed matter is directed to be agitated with a solution of eight ounces of muriate of ammonia in a gallon of boiling distilled water, before it is washed with pure water.

"Take of Muriate of Mercury [Corrosive Sublimate] *four parts;* Purified Mercury *three parts.* Rub the muriate into a fine powder, in a glass mortar, with a little water to prevent the acrid powder from rising; then add the Mercury, and rub again, until the metal is extinguished. Dry the matter, and having put it in an oblong phial, of which it should fill only one-third, sublime from warm sand. Reduce the sublimate to powder, and sublime it a second time; then rub it into a very fine powder, and lastly, wash it with boiling distilled water." *Ed.*

"Take of Persulphate of Mercury *twenty-five parts;* Purified Mercury *seventeen parts;* Dried Muriate of Soda *ten parts.* Triturate together the Persulphate of Mercury and Purified Mercury, in an earthenware mortar, until the metallic globules completely disappear. Then add the dried Muriate of Soda and mix them well; and from a suitable vessel, with a heat gradually raised, sublime the mixture into a receiver. Reduce the sublimate to powder, and wash it with water so long as the decanted liquid is precipitated by Water of Caustic Potassa. Lastly, dry the Sublimed Calomel." *Dub.*

The object of the above processes is to obtain a protochloride of mercury. This chloride consists of one equiv. of chlorine, and one of mercury, and consequently contains precisely half as much chlorine as corrosive sublimate, combined with the same quantity of mercury. In the process of the U.S. Pharmacopœia, as in the case of corrosive sublimate, a bisulphate of the peroxide is first formed; but instead of being immediately sublimed with the chloride of sodium (common salt,) it undergoes a preparatory trituration with the same quantity of mercury as was employed in forming it. This trituration may be conceived to take place between one equiv. of the *bisul-*

phate of the peroxide, and one equiv. of metallic mercury, which are converted into two equivalents of the *neutral* sulphate of the protoxide. This change will be easily understood, by adverting to the fact, that the bisulphate of the peroxide consists of two equiv. of sulphuric acid, two of oxygen, and one of mercury, and when rubbed up with one equiv. of additional mercury, the whole matter present becomes two equiv. of acid, two of oxygen, and two of mercury, evidently corresponding to two equiv. of the neutral protosulphate. The two equiv. of protosulphate thus formed, being heated with two equiv. of common salt, the two equiv. of chlorine in the latter sublime in union with the two equiv. of mercury in the former, and generate two equiv. of protochloride of mercury; while the two equiv. severally, of sulphuric acid, oxygen, and sodium, unite together to form two equiv. of dry sulphate of soda, which remains as a fixed residue. It is hence apparent, that the residue in this process is the same as in the ordinary process for corrosive sublimate.

Some writers explain the above process differently. Thus it is alleged that the trituration cannot reasonably be supposed chemically to unite metallic mercury with the bipersulphate, so as to convert it into protosulphate; and hence the process has been considered as one in which the materials for generating corrosive sublimate are sublimed in a state of intimate mixture with metallic mercury. According to this view, corrosive sublimate is first formed, and rising by the heat simultaneously with the mercury, unites with the metal and forms the calomel.

The calomel in mass as sublimed, is liable to contain a little corrosive sublimate; and hence the necessity of the directions of the U.S. Pharmacopœia, to reduce the sublimed matter to a very fine powder, and to wash it with boiling distilled water until liquid ammonia produces no precipitate in the water. The ammonia occasions a white precipitate so long as the washings contain corrosive sublimate; and when it ceases to produce this effect, the operator may rest satisfied that the whole of the poisonous salt has been removed. The direction of the London College, that the washing should first be performed with a hot solution of muriate of ammonia is improper; for while this muriate has the power of rendering corrosive sublimate more soluble, it has been shown by Mr. Hennel of London, to have the property also, when in hot solution, of converting a portion of the calomel itself into corrosive sublimate.

The *Edinburgh* process for calomel is peculiar in directing the sublimation of a mixture of corrosive sublimate and mercury, and the mode in which it is formed is thus explained. One equiv. of corrosive sublimate consists of two equiv. of chlorine and one of mercury. When rubbed up with one equiv. of metallic mercury and sublimed, the whole becomes two equiv. of chlorine and two of mercury; that is, two equiv. of calomel. The proportions employed are nearly those of the equivalents, giving merely a slight excess of mercury.

The process of the *Dublin* College is in effect the same as that of the U.S. and London Pharmacopœias; the only difference being, that in the former the bipersulphate of mercury is used ready formed, as prepared by a distinct formula of the Dublin Pharmacopœia, instead of being made as the first step of the process itself. The Dublin College does not direct that the water employed for washing the calomel should be hot. This omission renders the directions somewhat incomplete; for it is obviously preferable to wash with boiling water. The water of caustic potassa with which the washings are tested, is intended to detect corrosive sublimate, and will cause a yellow cloud as long as this salt is present in them. The proportions employed are nearly the equivalent quantities.

Of the different processes here commented upon, those of the U.S. and Dublin Pharmacopœias are obviously the best. The London process, though the same in principle, is liable to the objection of using, needlessly if not injuriously, a hot solution of muriate of ammonia; and the Edinburgh formula is expensive, as implying the previous preparation of corrosive sublimate. The chemical changes which take place may be readily explained on the old theory of muriatic acid, which has been sanctioned by the nomenclature adopted by the British Colleges. By this theory, calomel is a *neutral** muriate of the *prot*oxide of mercury. When it is generated according to the first plan mentioned in this article (*U. S.*, *Lond.*, and *Dub.* process), it becomes formed in consequence of a double decomposition between the protosulphate of mercury and muriate of soda (common salt), which results in the generation of neutral protomuriate of mercury (calomel), and sulphate of soda. When formed according to the second plan (*Edinburgh* process), one equiv. of *bi*muriate of the *per*oxide of mercury (corrosive sublimate), is triturated with one equiv. of metallic mercury, and made to unite with it by sublimation. The whole, after combination, is evidently two equiv. of muriatic acid, two of oxygen, and two of mercury, which correspond precisely with two equiv. of the neutral protomuriate, or calomel. From these explanations it becomes apparent, that the difference, according to the old theory, between the mercurial chlorides, is not merely that the base of calomel is a protoxide, while that of corrosive sublimate is a peroxide; but also that the base of the latter is combined with twice as much muriatic acid as is united with the base of the former. According even to the old theory, therefore, calomel is not a *sub*muriate, as it is called by the London and Edinburgh Colleges; although, on the erroneous assumption that corrosive sublimate is the *neutral* muriate, the name is defensible as relatively correct, in allusion to the fact that calomel contains only half as much muriatic acid combined with the base.

Preparation on the Large Scale. The process for making calomel by means of the bipersulphate of mercury, was originally practised at Apothecaries' Hall, London. The proportions taken, and the mode of proceeding, in that establishment, are, according to Mr. Brande, as follows:—50 pounds of mercury are boiled to dryness with 70 pounds of sulphuric acid, in a cast iron vessel. Sixty-two pounds of the dry salt formed are triturated with 40½ pounds of mercury till the globules disappear, and the whole is mixed with 34 pounds of common salt. The mixture is then heated in earthen vessels, and the product is from 95 to 100 pounds of calomel. The sublimate is next ground to an impalpable powder, and washed with a large quantity of distilled water.

The object of bringing calomel into a state of minute division, is more perfectly accomplished by the method of Mr. Jewell of London, for which he has taken out a patent. It consists in causing the calomel in vapour to come in contact with steam in the subliming vessel, whereby it is condensed in the form of an impalpable powder, and perfectly washed from corrosive sublimate, in the same operation. Calomel made by this process, sometimes called Jewell's or Howard's *hydrosublimate of mercury*, is lighter than that ordinarily prepared in the proportion of three to five, (*Paris's Pharmacologia*,) and free from all suspicion of containing corrosive sublimate; and as it is much finer than when obtained by levigation and elutriation, it probably possesses more activity as a medicine. This process has been admitted into the French Codex.

---

* By *neutral* is here meant, neutral in composition, as Dr. Turner terms it; that is, consisting of *one* equiv. of acid, and one of base.

Properties. Mild chloride of mercury is a tasteless, inodorous, insoluble substance, less volatile than corrosive sublimate, unalterable in the air, but blackening by long exposure to light. When in-mass, its form and appearance depend upon the shape and temperature of the subliming vessel. In this state, it is generally in the form of a white crystalline cake, the interior surface of which is studded with shining transparent crystals, having the shape of quadrangular prisms, and a texture somewhat horny and elastic. When the mass is scratched it yields a yellow streak, which is very characteristic. Its sp. gr. is 7.2. The officinal form of this chloride is that of powder, in which state it always exists in the shops. The powder has a light buff or ivory colour, if obtained by the levigation of sublimed masses, but if condensed at once in the form of an impalpable powder, as is the case with Jewell's calomel, it is perfectly white. To protect it from the action of the light, it should be kept in a dark place, or in bottles painted black or covered with black paper. By the action of the alkalies or alkaline earths it immediately becomes black, in consequence of the formation of protoxide. (See *Hydrargyri Oxidum Cinereum*, and *Hydrargyri Oxidum Nigrum.*) The composition of calomel has already been mentioned. The first European writer by whom it was described was Beguin, in 1608; but the researches of Mr. Hatchett seem to prove that it was long known and prepared in Thibet.

Tests of Purity, and Incompatibles. Calomel, when pure, completely sublimes on the application of heat, and strikes a black colour, free from reddish tinge, by the action of the fixed alkalies. The buff colour indicates the absence of corrosive sublimate; but whiteness by no means shows the presence of impurity. Its freedom from the corrosive chloride may be judged of by digesting a small portion of it in alcohol, and then testing the alcohol with caustic potassa or ammonia, the former of which will cause a yellow precipitate, the latter a white one, in case the menstruum has taken up any of this chloride. Besides being incompatible with the alkalies and alkaline earths, it is also decomposed by the alkaline carbonates, soaps, hydrosulphates, and, according to some authorities, by iron, lead, and copper. B.

Medical Properties and Uses. Calomel unites to the general properties of the mercurials, those of a purgative and anthelmintic. It is the most valuable of the mercurial preparations, and in extent of employment is inferior to few articles of the Materia Medica. Whether the object is to bring the system under the general influence of mercury, or to produce its alterative action upon the hepatic or other secretory functions, calomel, on account both of its certainty and mildness, is preferred to all other preparations, with the single exception of the blue pill, which, though less certain, is still milder, and is sometimes preferably employed. When used with the above objects, the tendency to purge which it sometimes evinces, even in very small doses, must be restrained by combining it with opium. In sialagogue or alterative doses, it is often prescribed with other medicines, which, while they give it a direction to certain organs, have their own peculiar influence increased by its co-operation. Thus it renders squill more diuretic, nitre and the antimonials more diaphoretic, and seneka more expectorant.

As a purgative, calomel owes its chief value to its tendency to the liver, the secretory function of which it powerfully stimulates. It is usually slow and somewhat uncertain in its cathartic effect, and though itself unirritating, sometimes occasions severe griping pain with bilious vomiting, attributable to the acrid character of the bile which it causes the liver to secrete. It is peculiarly useful in the commencement of bilious fevers, in hepatitis, jaundice, bilious and painters' colic, dysentery, especially that of tropical climates, and all other affections attended with congestion of the portal system, or torpidity of the hepatic vessels. The difficulty with which it is thrown from the stomach, renders it highly useful in some cases of obstinate vomiting, when other remedies are rejected. In the cases of children, it is peculiarly valuable from the facility of its administration; and in the febrile complaints to which they are subject, appears to exercise a curative influence, depending on some other cause than its mere purgative effect, and perhaps referrible to its action upon the liver. In the treatment of worms it is one of the most efficient remedies, acting probably not only as a purgative, but also as an irritant to the worms, either by its immediate influence, or that of the acrid bile which it causes to flow. The slowness and uncertainty of its action, and its liability to salivate if too long retained in the bowels, render it proper either to follow or combine it with other cathartics, in order to ensure its purgative effect. When given alone, it should be followed, if it do not operate in six or seven hours, by a dose of castor oil or sulphate of magnesia. The cathartics with which it is most frequently combined are jalap, rhubarb, aloes, scammony, colocynth, and gamboge. It is often added in small quantities to purgative combinations, with a view to its influence on the biliary organs.

It is sometimes used as an errhine in amaurosis, mixed with twice its weight of sugar, or other mild powder; and in the same combination is occasionally employed to remove specks and opacity of the cornea. For this latter purpose, Dupuytren recommends particularly the calomel prepared according to the plan of Mr. Jewell. Calomel is also sometimes employed externally in herpetic and other eruptions, in the shape of an ointment.

The dose as an alterative in functional derangement of the liver, is from half a grain to a grain every night, or every other night, followed in the morning, if the bowels are not opened, by a gentle saline laxative. When the stomach or bowels are very irritable, as in cholera and diarrhœa, from an eighth to a quarter of a grain may be given every hour or two, so as to amount to one or two grains in the course of the day. With a view to salivation, the dose is from half a grain to a grain three or four times a day, to be increased considerably in urgent cases. When large doses are given with this view, it is often necessary to combine them with opium. As a purgative, from five to fifteen grains or more may be given. Calomel has the peculiarity that its cathartic action is not increased in proportion to the dose, and enormous quantities have sometimes been given with impunity. In yellow fever, tropical dysentery, &c., from twenty grains to a drachm have been given and repeated at short intervals, without producing hypercatharsis; but this practice is justifiable only in cases of extreme urgency, in which salivation as well as purgation is indicated. Even in very small doses of not more than one, two, or three grains, calomel purges some individuals briskly. In these persons, large doses, though they do not proportionably increase the evacuation, often occasion excessive spasmodic pain in the stomach and bowels. For children, larger doses are generally required in proportion than for adults. Not less than from three to six grains should be given to a child two or three years old, and this quantity often fails to act on the bowels, unless assisted by castor oil, or some other cathartic. Calomel may be given in pill made with gum Arabic and syrup, or in powder mixed with syrup or molasses.

CALOMELAS PRÆCIPITATUM. *Dub.* SUB-MURIAS HYDRARGYRI PRÆCIPITATUS. *Ed.* *Precipitated Calomel. Precipitated Sub-Muriate of Mercury.*

"Take of Purified Mercury *seventeen parts;* Diluted Nitric Acid *fifteen parts.* Pour the Acid upon the Mercury in a glass vessel; and when the mixture shall have ceased to effervesce, digest with a medium heat, with occasional agitation for six hours. Then increase the heat that the liquor may boil for a short time, and afterwards pour it off from the residual Mercury, and quickly mix it with *four hundred parts* of boiling Water, containing *seven parts* of Muriate of Soda in solution. Wash the powder which subsides with warm Distilled Water, as long as the liquor decanted from it is precipitated by the addition of a few drops of Water of Caustic Potassa; and, lastly, dry it." *Dub.*

The *Edinburgh College* orders *eight ounces,* each, of diluted nitrous acid and purified mercury, *four ounces and a half* of muriate of soda; and *eight pounds* of boiling water, and treats the materials generally as directed in the Dublin formula.

The method of forming calomel in the humid way, or by precipitation, was first proposed by Scheele. It consists of two steps; first, the formation of a protonitrate of mercury by dissolving the metal in weak nitric acid, and secondly, the decomposition of this salt by means of a hot solution of common salt. The latter compound may be supposed to become by solution, muriate of soda, and when it reacts upon the protonitrate, a double decomposition takes place. The nitric acid combines with the soda, and remains in solution as nitrate of soda, while the elements of the muriatic acid and protoxide of mercury unite in such a manner as to form water and protochloride of mercury, the latter of which precipitates. Though this process is sufficiently simple in theory, the performance of it is attended with some difficulty. It is necessary, in the first place, to prepare a pure *proto*nitrate, an object in which the operator is apt to miscarry, in consequence of the liability of the metal to become peroxidized by the action of nitric acid. To guard against this result, weak nitric acid is employed, more mercury is ordered than the acid can dissolve, and a moderate heat is applied, and that only after the effervescence has ceased. In the next place, the operator must guard against the precipitation of a subnitrate, which is always thrown down by the action of water upon the *neutral* nitrate. To prevent the production of this impurity, it is necessary slightly to acidulate the nitric solution of the mercury with nitric acid, or the solution of common salt with muriatic acid; for an excess of acid in either of the solutions effectually prevents the formation of the subnitrate. This necessary precaution has been omitted in the directions of the Dublin and Edinburgh Colleges. The reason why the peroxidation of the metal, and consequently the production of bipernitrate is to be avoided, is, that this salt, by double decomposition with the solution of muriate of soda, generates corrosive sublimate in solution, which, in this state, may be viewed as a bipermuriate. The result is thus explained. The two equiv. of nitric acid combine with two equiv. of soda, and thereby cause the decomposition of two equiv. of the dissolved muriate of soda. Two equiv. of muriatic acid are thus set free, which, by uniting with the peroxide of mercury, form the bipermuriate in solution, or corrosive sublimate. The production of corrosive sublimate in this way in the process will not injure the precipitated calomel, provided this be thoroughly washed; but it is objectionable as diminishing its quantity. When, however, the subnitrate is allowed to be formed, it contaminates the precipitated calomel, and, from its insolubility, cannot be separated by washing. As, notwithstanding every precaution, corrosive sublimate will be formed in this process, the liquor poured off from the precipitated calomel should be reserved for forming *white precipitate*, as is directed by the Dublin College. (See *Hydrargyrum Ammoniatum.*)

Properties, &c. Precipitated calomel, when properly prepared, scarcely differs in properties from sublimed calomel. It is stated to be whiter, smoother, and lighter than when obtained by sublimation. Another difference, according to Göttling, is, that the precipitated calomel produces a gray, while the sublimed causes a black colour, when triturated with lime-water. The presence of subnitrate may be detected by digesting the calomel in water containing a little nitric acid, and then testing the acid by an alkali, which will cause a precipitate, if any subnitrate has been taken up. Corrosive sublimate is discovered by testing alcohol, digested on a portion of it, by ammonia or caustic potassa.

The medical properties of precipitated calomel are the same as those of the ordinary sublimed calomel. By some it is supposed to be more purgative. Upon the whole, it may be viewed as a superfluous preparation. B.

HYDRARGYRI CYANURETUM. *U.S., Dub.* *Cyanuret of Mercury. Prussiate of Mercury.*

"Take of Red Oxide of Mercury *three ounces;* Ferrocyanate of Iron [Prussian Blue] *six ounces;* Distilled Water *three pints.* Put the Oxide of Mercury and the Ferrocyanate of Iron, previously powdered and thoroughly mixed together, in a glass vessel; and pour upon them two pints of the Distilled Water. Then boil the mixture, stirring constantly, till it becomes of a yellowish colour; after which filter it through paper. Wash the residue in a pint of Distilled Water, and filter as before. Mix the solutions, and evaporate by the fire till a pellicle appears; then set the liquor aside that crystals may form. To purify the crystals, dissolve them again in distilled water, filter and evaporate the solution, and set it aside to crystallize." *U.S.*

"Take of Cyanuret of Iron [Prussian Blue] *six parts;* Nitric Oxide of Mercury [Red Precipitate] *five parts;* Distilled Water *forty parts.* Mix the Cyanuret of Iron and Oxide of Mercury, and then add them to the Water previously warmed. Boil the mixture with constant stirring, for half an hour, and filter through bibulous paper. Wash the residue frequently with warm Distilled Water. Lastly, filter the liquors, and evaporate them until they furnish crystals by refrigeration." *Dub.*

The above processes are essentially the same; their object being to present cyanogen and mercury to each other under favourable circumstances for combination. The compound formed consists of two equiv. of cyanogen, and one of mercury. It is, therefore, properly speaking, a *bi*cyanuret. As Prussian blue is a cyanuret of iron, the reaction which occurs is a case of double decomposition, resulting in the formation of bicyanuret of mercury, and peroxide of iron. The U.S. and Dublin formulæ present a great disparity in the proportions of the reacting ingredients employed. In favour of the proportions adopted in the U.S. Pharmacopœia, it may be stated that they are the same with those adopted in the Paris Codex, and which are recommended by Berzelius. As Prussian blue is of variable quality, perhaps the best rule in conducting the process, would be to add the red oxide of mercury at intervals to the boiling water containing the Prussian blue, until the blue colour is replaced by a bright brown, a change indicative of the complete decomposition of the ferruginous cyanuret.

Winkler prepares the bicyanuret of mercury by the following process. Mix 15 parts of ferrocyanate (prussiate) of potassa in powder with 13 parts of concentrated sulphuric acid, and 100 parts of water. Distil the mixture to dryness into a receiver, containing 30 parts of water. The ferrocyanate is decomposed, sulphate of potassa is formed in the retort, and hydrocyanic acid distils over. Of the acid thus obtained, reserve a portion, and mix the rest with 16 parts of red oxide of mercury in fine powder, and stir the mixture till the odour of hydrocyanic acid has entirely disappeared. Then decant the liquor, and add for the purpose of saturating it, the portion of acid that had been reserved. This process gives 12 parts of the bicyanuret. If the liquor were not treated with free hydrocyanic acid after having acted on the red oxide, it would probably contain some of this oxide in excess, and when evaporated would yield, instead of the bicyanuret, a peculiar salt, composed of this cyanuret and the red oxide, which crystallizes in small acicular crystals.

Properties, &c. Cyanuret of mercury is a white substance, permanent in the air, and crystallized in quadrangular obliquely truncated prisms, which are devoid of water of crystallization, and have a disagreeable styptic taste. It is but sparingly soluble in alcohol, but dissolves readily in cold water, and much more abundantly in hot. When heated it yields cyanogen, and mercury remains behind. It acts on the animal economy as a potent poison. It has been occasionally tried as a remedy in syphilis, in doses of from an eighth to a sixth of a grain; but it was introduced into the U.S. and Dublin Pharmacopœias, for the purpose of being employed in the preparation of hydrocyanic acid. Its composition has been already given. For the properties and composition of cyanogen, see *Acidum Hydrocyanicum.*

HYDRARGYRI OXYDUM CINEREUM. *Lond.* OXIDUM HYDRARGYRI CINEREUM. *Ed.* *Gray Oxide of Mercury.*

"Take of Submuriate of Mercury [Calomel] *an ounce;* Lime-water *a gallon.* Boil the Submuriate of Mercury in the Lime-water, stirring constantly, until the Gray Oxide of Mercury subsides. Wash this with distilled water; then dry it." *Lond.*

"Take of Sub-Muriate of Mercury *half an ounce;* Lime-water *five pounds.* Boil the Sub-Muriate in the Lime-water for a quarter of an hour in a lightly covered vessel. Pour off the supernatant liquor, wash the Oxide with distilled water, and then dry it." *Ed.*

The object of these processes is to obtain the protoxide or black oxide of mercury, which was at one time believed to be the active constituent of those preparations, in which the metal is minutely divided by trituration. When calomel is agitated with lime-water, a portion of the water is decomposed, giving its hydrogen to the chlorine of the calomel to form muriatic acid which unites with the lime, and its oxygen to the metal to form protoxide of mercury. The muriate of lime remains in solution, and the oxide subsides. But it is extremely difficult completely to decompose calomel in this manner, on account of the obstacle which its insolubility and the dilute nature of the solution of lime presents to that close contact of particles which is essential to the chemical reaction of different bodies on each other. Hence the protoxide, in this preparation, is almost always mixed with a portion of calomel, which is greater or less, according to the care with which the process has been conducted. When the proportion is large, the powder has the grayish colour to which it owes its officinal title; when very small, it scarcely differs in appearance or properties from the oxide described under the following head. From the uncertainty of its composition, it should be discarded from the officinal lists, as it generally has been from practical use.

Off. Prep. Unguentum Oxidi Hydrargyri Cinerei, *Ed.* W.

HYDRARGYRI OXIDUM NIGRUM. *U.S.* HYDRARGYRI OXYDUM NIGRUM. *Dub.* *Black Oxide of Mercury.*

"Take of Mild Chloride of Mercury [Calomel], Potassa, each, *four ounces;* Water *a pint.* Dissolve the Potassa in the Water, and when the dregs shall have subsided, pour off the clear solution. To this add the Chloride of Mercury, and stir them constantly together, till the Black Oxide is formed. Having poured off the supernatant liquor, wash the Black Oxide with Distilled Water, and dry it with a gentle heat." *U. S.*

"Take of Sublimed Calomel *one part;* Water of Caustic Potassa, heated, *four parts.* Rub them together until an oxide of a black colour is obtained; wash this frequently with water, and dry it upon bibulous paper with a *medium* heat." *Dub.*

These processes afford the protoxide of mercury in a purer state than the preceding. Calomel is completely decomposed by the solution of potassa; its chlorine being converted by union with the hydrogen of the water into muriatic acid, which combines with the potassa and remains in solution, while the mercury unites with the oxygen of the water to form the protoxide of that metal, which subsides. The U.S. and Dublin processes are essentially the same. In both, more potassa is employed than by calculation would seem to be requisite; but it has been ascertained by experiment, that a considerable excess is necessary for the complete decomposition of the calomel. In the U.S. process, however, the quantity is, perhaps, unnecessarily large; being more than double the proportion contained in the "water of caustic potassa," directed by the Dublin College. The use of the officinal solution of potassa is preferable, on the score of economy, to that of a solution extemporaneously prepared from the caustic alkali. In order to ensure the success of the process, the calomel, very finely levigated, should be rubbed quickly with the alkaline solution in a mortar; and the resulting oxide should be dried in the dark with a very gentle heat, as it is decomposed by the agency both of light and of an elevated temperature. For the same reason it should be preserved in an opaque bottle. This mode of preparing the black oxide of mercury was introduced into use by Mr. Donovan.

The oxide may also be prepared by decomposing a solution of the protonitrate of mercury by the solution of potassa. The protonitrate may be obtained by treating twenty parts of mercury with eighteen parts of nitric acid of 25° Baumé, adding, when nitrous vapours cease to rise, ten parts of warm distilled water, boiling for a short time, decanting the clear liquor, and setting it aside to crystallize. The mother waters by evaporation will furnish a new product of crystals of protonitrate. (*Ratier's Pharm. Franc.*) The preparation, formerly officinal in the Dublin Pharmacopœia under the name of *Pulvis Hydrargyri Cinereus*, made by adding carbonate of ammonia to a solution of mercury in heated nitric acid, was a mixture of subnitrate of mercury and ammonia with the protoxide of mercury.

Properties, &c. As first prepared, this oxide is greenish-black; but as found in the shops it is almost always of an olive colour, owing, it is supposed, to the chemical changes which it undergoes. It is inodorous, tasteless, and insoluble in water; and consists of one equiv. of mercury 202, and one equiv. of oxygen 8=210. On exposure to light or heat it is decomposed, one part assuming the metallic state, in consequence of the loss of its oxygen, which converts another part into the peroxide. The preparation, therefore, becomes a mixture of the protoxide, the peroxide, and metallic mercury, with which calomel is sometimes associated, in consequence of the incomplete decomposition of that originally employed in the process. When pure it is soluble in acetic, and entirely insoluble in muriatic acid. If it contain the peroxide, this is dissolved by muriatic acid, and may be detected in the solution by the production of a white precipitate with water of ammonia, and of a yellow one with solution of potassa. Calomel, if present, may be discovered by boiling the powder with a solution of potassa, thus forming a muriate of that base, which, when the solution is saturated with nitric acid, will afford a white precipitate of chloride of silver on the addition of nitrate of silver. (*Phillips.*)

Medical Properties and Uses. The black oxide is alterative, sialagogue, and purgative. It may be employed for the same purposes with calomel, over which, however, it has not in our hands exhibited any superiority, while, from the occasional presence of the peroxide, it must be liable to operate harshly. The idea under which it was introduced into use, that it was the basis of the blue pill, is probably erroneous. Made into an ointment with lard, according to the process of Donovan, it may be applied externally with good effect in bringing the system under the mercurial influence. (See *Unguentum Hydrargyri.*) Its dose as an alterative is one-fourth or half a grain daily, as a sialagogue from one to three grains two or three times a day, given in the form of pill. W.

HYDRARGYRI OXIDUM RUBRUM. *U. S.* HYDRARGYRI NITRICO-OXIDUM. *Lond.* OXIDUM HYDRARGYRI RUBRUM per Acidum Nitricum. *Ed.* HYDRARGYRI OXYDUM NITRICUM. *Dub.* *Red Oxide of Mercury. Red Precipitate.*

"Take of Purified Mercury *three pounds;* Nitric Acid *a pound and a half;* Distilled Water *two pints.* Mix them in a glass vessel, and boil till the Mercury is dissolved, and a white mass remains after the evaporation of the Water. Rub this into powder, and throw it into a very shallow vessel; then apply a gentle heat, and gradually increase it, till red vapours cease to arise." *U. S., Lond.*

"Take of Purified Mercury *three parts;* Diluted Nitrous Acid *four parts.* Dissolve the Mercury, and evaporate the solution, with a gentle heat, to a dry white mass; which, having been rubbed into powder, is to be put into a glass cucurbit, and covered with a thick glass plate. Then, a capital having been adapted, and the vessel placed in a sand-bath, let the contained matter be roasted by a gradually increased heat, until the matter is converted into small bright red scales." *Ed.*

"Take of Purified Mercury *two parts;* Diluted Nitric Acid *three parts.* Dissolve the Mercury, and let heat be applied until the dried mass is converted into red scales." *Dub.*

The white mass obtained in the first of these processes is either the pernitrate of mercury, or a mixture of the pernitrate and protonitrate. When exposed to a strong heat it is decomposed, giving out red nitrous fumes, and assuming successively a yellow, orange, and brilliant purple-red colour, which becomes orange-red on cooling. These changes are owing to the gradual separation and decomposition of the nitric acid, by the oxygen of which the protoxide of the protonitrate, if any be present, is converted into peroxide, while nitric oxide gas escapes, and takes the form of nitrous acid vapour on contact with the air. The peroxide of mercury is left behind, but not entirely free from nitric acid, which cannot be wholly expelled by heat, without endangering the decomposition of the oxide itself, and the volatilization of the metal. The preparation is, in common language, called *red precipitate.* The name of *red oxide of mercury*, by which it is designated in the U. S. Pharmacopœia, is appropriate, as the nitric acid exists merely as an incidental impurity; and there is no occasion to distinguish the preparation from the pure peroxide obtained by heating mercury, as the latter is not recognised in our Pharmacopœia, and is never employed in this country.

In the preparation of this mercurial, various circumstances influence in some measure the nature of the product, and must be attended to, if we desire to procure the oxide with that fine bright orange-red colour, and shining scaly appearance, which are usually considered desirable. Among these circumstances is the condition of the nitrate of mercury submitted to calcination. According to Gay-Lussac, it should be employed in the form of small crystalline grains. If previously pulverized, as directed in the U.S., London, and Edinburgh processes, it will yield an orange-yellow powder; if it be in the state of large and dense crystals, the oxide will have a deep orange colour. Care must also be taken that the mercury and acid be free from impurities. It is highly important that sufficient nitric acid be employed fully to saturate the mercury. The quantity directed in the U. S. and London Pharmacopœias is deficient by theory, and, as we have been informed, has not been found to answer in practice. M. Payssé, who paid great attention to the manufacture of red precipitate, recommends 70 parts of nitric acid from 34° to 38° Baumé, to 50 parts of mercury. This, however, is an excess of acid. We have been told by a skilful practical chemist of Philadelphia, that he has found, by repeated experiment, 7 parts of nitric acid of 35° Baumé, to be sufficient fully to saturate 6 parts of mercury. Less will not answer, and more would be useless. It is not necessary that the salt should be removed from the vessel in which it is formed; and it is even asserted that the product is always more beautiful when the calcination is performed in the same vessel. A matrass may be used with a large flat bottom, so that an extended surface may be exposed, and all parts heated equally. The metal and acid having been introduced, the matrass should be placed in a sand-bath, and covered with sand up to the neck. The solution of the mercury should be favoured with a gentle heat, which should afterwards be gradually increased till red vapours make their appearance, then maintained as equably as possible till these vapours cease, and at last slightly elevated till oxygen gas begins to escape. This may be known by the increased brilliancy with which a taper will burn if placed in the mouth of the matrass, or by its rekindling if partially extinguished. Too high a temperature must be carefully avoided, as it decomposes the oxide, and volatilizes the mercury. At the close of the operation, the mouth of the vessel should be stopped, and the heat gradually diminished, the matrass being still allowed to remain in the sand-bath. These last precautions are said to be essential to the fine red colour of the preparation. It is best to operate upon a large quantity of materials, as the heat may be thus more steadily and uniformly maintained.

As the process is ordinarily conducted in chemical laboratories, the nitrate of mercury is decomposed in shallow earthen vessels, several of which are placed upon a bed of sand in the chamber of an oven or furnace provided with a flue for the escape of the vapours. Each vessel may conveniently contain ten pounds of the nitrate. There is always some loss in the operation conducted in this way.

Properties, &c. Red precipitate, when well prepared, has a brilliant red colour with a shade of orange, a shining scaly appearance, and an acrid taste. It is very slightly soluble in water, of which Dr. Barker found 1000 parts to take up only 0.62 of the oxide. Nitric acid dissolves it without effervescence. At a red heat it is decomposed and entirely dissipated. As before stated it is not a perfectly pure peroxide; but is mixed with a minute proportion of nitric acid, probably in the state of subpernitrate. Perhaps it is to this salt, which is of a yellow colour, that red precipitate owes the orange tint which distinguishes it from the red oxide procured by heating metallic mercury. According to Brande, when rubbed and washed with a solution of potassa, edulcorated with distilled water, and carefully dried, it may be regarded as a nearly pure peroxide. It is said to be sometimes adulterated with brickdust, red lead, &c.; but these may be readily detected, as the oxide of mercury is wholly dissipated if thrown upon red-hot iron.

Medical Properties and Uses. This preparation is too harsh and irregular in its operation for internal use, but is much employed externally as a stimulant and escharotic, either in the state of powder or of ointment. In the former state it is sprinkled on the surface of chancres, and indolent, flabby, or fungous ulcers; and mixed with 8 or 10 parts of finely powdered sugar is sometimes blown into the eye to remove opacity of the cornea. The powder should be finely levigated. The ointment is officinal. (See *Unguentum Hydrargyri Oxidi Rubri.*)

HYDRARGYRI OXYDUM RUBRUM. *Lond.*, *Dub.* *Red Oxide of Mercury. Precipitate per se. Calcined Mercury.*

"Take of Purified Mercury *a pound*. Put it into a tall glass vessel, with a narrow mouth and broad bottom. To this vessel, unclosed, apply a heat of 600°, till the Mercury passes into red scales; then rub them into a very fine powder." *Lond.*

"Take of Purified Mercury *any quantity*. Put it into an open glass vessel, with a narrow mouth and broad bottom, and expose it to a heat of about 600°, till it is converted into red scales." *Dub.*

As mercury requires for its oxidation a temperature little short of its boiling point, it is necessary that the vessel in which it is heated be so constructed as to prevent the escape of the vapour which rises during the process. A glass matrass is usually employed, having a narrow neck, drawn out at top into an almost capillary orifice. But the arrangement which serves to confine the mercurial vapour, impedes also the free access of air; so that the process is exceedingly tedious. The mercury introduced should not be more than sufficient to cover the bottom of the vessel, which should be heated by means of a sand-bath till vapours begin to rise. These are condensed in the upper part of the matrass, and by maintaining the temperature steadily at this point, a constant circulation of vapour is kept up within the vessel. The metal very slowly combines with the oxygen, forming first a black, and then a red powder, molecules of which begin to appear after some days, and gradually increase till they cover the surface of the mercury. Care must be taken not to increase the heat too much, as not only is the mercury thus volatilized, but the oxide already formed is decomposed. Several weeks are requisite for the complete oxidation of a small portion of metal, and the process is necessarily expensive. The preparation is the *hydrargyrum præcipitatum per se*, or *precipitate per se* of the older chemical writers.

Properties, &c. It is in minute, sparkling, crystalline scales, of a deep red colour becoming still deeper by heat, inodorous, of an acrid taste, very slightly soluble in water, and freely soluble in nitric, muriatic, and some other acids. Its aqueous solution changes the infusion of violets to green.

It consists of one equiv. of mercury 202, and two of oxygen 16=218. At a red heat it is decomposed, oxygen being given off, and the mercury revived. Its solutions in the acids afford, with potassa and soda, an orange-coloured precipitate of the peroxide, and with ammonia a white precipitate, consisting of the acid, peroxide, and ammonia. Its high price affords an inducement for adulteration, to avoid which it should be kept in the crystalline state, and not in powder as directed by the London College. If pure, it is wholly volatilized by a red heat.

Medical Properties and Uses. It has the general properties of the mercurial preparations, but is apt to vomit and purge, and to act otherwise violently on the stomach and bowels. Though formerly used in the treatment of syphilis, it has been entirely abandoned. It has been employed externally for the same purposes with the red precipitate; but is much more costly, without having any superiority. In this country it is almost unknown as a medicine. The dose may be from one-sixth of a grain to a grain. W.

HYDRARGYRI PERSULPHAS. *Dub.* *Persulphate of Mercury.*

"Take of Purified Mercury, Sulphuric Acid, each, *six parts;* Nitric Acid *one part.* Expose them to heat in a glass vessel, and increase the heat until the mass becomes white and perfectly dry." *Dub.*

When an excess of sulphuric acid is boiled to dryness upon mercury, the metal is peroxidized at the expense of part of the acid, sulphurous acid is copiously evolved, and the peroxide formed unites with the undecomposed portion of the sulphuric acid, so as to form the *bi*sulphate of the peroxide of mercury, which is the persulphate of the Dublin College. In the Dublin formula, the peroxidation of the metal is assisted by a small portion of nitric acid, the use of which, though not essential to the result, is stated by Dr. Barker to facilitate and shorten the process, and to afford a much whiter salt than when sulphuric acid alone is employed. When the nitric acid is used, orange-coloured fumes are given off on the first application of the heat, and the acid is totally decomposed.

Persulphate of mercury, as obtained by a separate formula, is peculiar to the Dublin Pharmacopœia; but it is formed as the first step of the processes of the other Pharmacopœias for obtaining corrosive sublimate and turpeth mineral, and of the U.S. and London Pharmacopœias for procuring sublimed calomel. The adoption of a separate formula and distinct officinal name for this salt, is certainly an improvement on the part of the Dublin College; as it obviates the necessity of repeating the process for obtaining the same substance in several distinct formulæ. On account of its important uses, it requires to be made on a large scale by the manufacturing chemist and the process is generally performed in a cast-iron vessel, which should be conveniently arranged for the escape and decomposition of the sulphurous acid fumes, which otherwise become a serious nuisance to the neighbourhood. The best way to effect this purpose is to allow them to pass off through a very lofty chimney mixed with abundance of coal smoke.

Properties, &c. Persulphate of mercury is in the form of a white saline mass. It consists of two equiv. of acid 80.2 and one of peroxide of mercury 218=298.2. It has no medical uses.

Off. Prep. Calomelas sublimatum, *Dub.;* Hydrargyri Murias Corrosivum, *Dub.;* Hydrargyri Oxidum Sulphuricum, *Dub.* B.

HYDRARGYRI SULPHAS FLAVUS. *U.S.* SUB-SULPHAS HYDRARGYRI FLAVUS. *Ed.* HYDRARGYRI OXYDUM SULPHURICUM. *Dub.* *Yellow Sulphate of Mercury. Turpeth Mineral.*

"Take of Purified Mercury *four ounces;* Sulphuric Acid *six ounces.* Mix in a glass vessel, and boil, by means of a sand-bath, till a dry white mass remains. Rub this into powder and throw it into boiling water. Pour off the supernatant liquor, and wash the yellow precipitated powder repeatedly with hot water; then dry it." *U. S.*

The *Edinburgh* formula is the same as the above, except in phraseology.

"Take of Persulphate of Mercury *one part;* Warm Water *twenty parts.* Rub them together in an earthenware mortar, and pour off the supernatant liquor. Wash the yellow powder with warm distilled Water so long as the decanted liquor is precipitated by the addition of a few drops of the Water of Caustic Potassa. Lastly, dry the Sulphuric Oxide of Mercury." *Dub.*

By referring to the articles on corrosive sublimate and calomel, it will be found that the peculiar salt which is generated by boiling sulphuric acid on mercury to dryness, is directed to be obtained as the first step of several of the processes; and here it is perceived that in the U.S. and Edinburgh formulæ, the same salt is again directed to be formed. The Dublin College has very properly avoided these repetitions, by adopting a distinct formula and name for the salt in question. We have already mentioned that this compound is the bisulphate of the peroxide of mercury. When obtained as the first step in the processes for corrosive sublimate and calomel, the proportion of metal and acid uniformly adopted is as 4 to 5; when procured by the separate formula of the Dublin College, the quantities used are equal parts; while the proportion directed in the U.S. and Edinburgh formulæ for turpeth mineral is as 2 to 3. There can be no good reason for these discrepancies, and, therefore, some uniform proportion should be selected. We incline to believe that 4 of metal to 5 of acid is the most eligible proportion. The Dublin College may, perhaps, be justifiable in using less sulphuric acid; as, in their formula for the bipersulphate, the mercury is partly oxidized at the expense of the nitric acid employed. (See the preceding article, where the formation of this salt is explained.)

When the bipersulphate of mercury is thrown into boiling or even warm water it is instantly decomposed, and an insoluble salt is precipitated, which is the turpeth mineral. The change which takes place is generally supposed to consist in the separation, by the action of the water, of one equiv. of sulphuric acid; and, on this supposition, the preparation under consideration would be simply a sulphate of the peroxide of mercury. But it would appear that the water separates something more than sulphuric acid; for the supernatant liquid is found to contain mercury, and, when duly evaporated, will yield a salt in white, crystalline, deliquescent needles. Berzelius is of opinion that the water resolves the bipersulphate into an insoluble subsesquisulphate, and a soluble supersulphate containing six equiv. of acid to one of base; and this view corresponds better with the facts than the other.

Properties, &c. Yellow sulphate of mercury is in the form of a powder of a lemon-yellow colour, and possessing a somewhat acrid taste. It dissolves in 2000 parts of cold water, and in about 600 parts at the boiling temperature. When exposed to a moderate heat, it becomes first red and afterwards brownish-red, but regains its original colour on cooling. (*Barker.*) At a red heat it is decomposed and dissipated without residue. It was originally called *turpeth* mineral, from the resemblance of its colour to that of the root of the *Ipomœa Turpethum*, a plant formerly used in medicine. It consists, according to most authorities, of one equiv. of sulphuric acid and one of peroxide of mercury; but according to Berzelius, of one equiv. of sulphuric acid, and an equiv. and a half of peroxide. Though its composition is not well settled, it is evidently not a mere *oxide* of mercury, as called by the Dublin College; and even if it were an oxide, the prefix of this College—*sulphuric*—is not in accordance with any recognised principle of nomenclature.

Medical Properties and Uses. Turpeth mineral is alterative, and powerfully emetic and errhine. As an alterative, it has been given in leprous disorders and glandular obstructions. It has been employed with benefit as an emetic, repeated every few days, in chronic enlargements of the testicle; but it often operates with great violence, and is apt to excite severe ptyalism. It proves useful in these cases upon the principle of revulsion, and by giving activity to the absorbents. As an errhine, it has been used with advantage in chronic ophthalmia, and in diseases of the head; and it sometimes produces salivation when thus employed. The dose, as an alterative, is from a quarter to half a grain; as an emetic, from two to five grains. When employed as an errhine, one grain may be mixed with five grains of starch or powdered liquorice root. B.

HYDRARGYRI SULPHURETUM NIGRUM. *U.S., Lond., Dub.* SULPHURETUM HYDRARGYRI NIGRUM. *Ed. Black Sulphuret of Mercury. Ethiops Mineral.*

"Take of Purified Mercury, Sulphur, each, *a pound.* Rub them together in a glass mortar till all the globules disappear." *U.S.*

The *London* process is the same as the above, except that it does not designate the kind of vessel in which the trituration is to be performed. The *Edinburgh College* takes equal parts of the materials, and directs the use of a glass mortar and pestle, and at the end of the formula, mentions that the preparation may be made with a double proportion of mercury. The *Dublin College* takes equal parts also, and orders the trituration to be performed in a stoneware mortar.

Mercury and sulphur have a strong affinity for each other; as is shown by the fact, that when they are triturated together in quantities, the mixture grows hot, cakes, and exhales a sulphureous odour. When rubbed together in equal weights, as directed in the Pharmacopœias, they are supposed to unite chemically; but the proportion of sulphur is much greater than is necessary to form a definite compound. Only two sulphurets of mercury have been admitted by the generality of chemists, a protosulphuret, and a bisulphuret or cinnabar; and the quantity of sulphur, directed in the above processes, is much more than sufficient to form even the latter. Thus, it still remains an unsettled point, what is the exact nature of the officinal black sulphuret, or *ethiops mineral.* Mr. Phillips supposes it to be a mixture of protosulphuret and sulphur; but it appears to have been experimentally proved by Mr. Brande to be a bisulphuret mixed with a portion of sulphur. Thus it was found by the latter chemist, that when boiled repeatedly in a solution of potassa, sulphur was dissolved by the alkali, and a black insoluble powder was left, which sublimed, without decomposition, into a substance having all the characters of cinnabar.

Ethiops mineral is sometimes obtained by melting the sulphur in a crucible, and adding the mercury to it; but when thus prepared, the sulphur is apt to become acidified, and the preparation to acquire an activity which does not belong to it when obtained by trituration. The latter method, accordingly, ought always to be employed.

Properties, &c. Black sulphuret of mercury is in the form of an insoluble, tasteless, very black powder. When exposed to heat, it becomes of a dark violet colour, emits its excess of sulphur in sulphurous acid fumes, and sublimes in brilliant red needles without residue. When well prepared, no globules of mercury should be discernible in it upon being viewed with a magnifier; and if rubbed on a gold ring, it should not communicate a white colour. Ivory black is detected in it, by throwing a small portion on a red-hot iron, when a white matter—phosphate of lime—will be left behind. Adulteration by sulphuret of antimony is shown, when muriatic acid boiled on a portion of the powder, acquires the property of causing a precipitate of oxychloride of antimony, upon being added to water. Adopting the views of Mr. Brande, ethiops mineral consists of one equiv. of bisulphuret of mercury, mixed with ten and a half equiv. of sulphur in excess.

Medical Properties and Uses. Ethiops mineral is supposed to be alterative, and as such is sometimes prescribed in glandular affections and cutaneous diseases. It has been given in scrofulous swellings, occurring in children; and from the mildness of its operation has been esteemed well suited to such cases. The dose generally given is from five to thirty grains, repeated several times a day; but it has often been administered in much larger doses, without producing any obvious impression on the system. The late Dr. Duncan stated that he had given it in doses of several drachms for a considerable length of time, with scarcely any effect. B.

HYDRARGYRI SULPHURETUM RUBRUM. *U.S., Lond., Dub.* SULPHURETUM HYDRARGYRI RUBRUM. *Ed.* *Red Sulphuret of Mercury. Cinnabar.*

"Take of Purified Mercury *forty ounces;* Sulphur *eight ounces.* Mix the Mercury with the Melted Sulphur over the fire; and, as soon as the mass begins to swell, remove the vessel from the fire, and cover it with considerable force, to prevent combustion; then rub the mass into powder, and sublime." *U.S.*

The *London* process, which is the original of the above, only differs from it in phraseology.

"Take of Purified Mercury *nineteen parts;* Sublimed Sulphur *three parts.* Mix the Mercury with the melted Sulphur; and if the mixture takes fire, extinguish the flame by covering the vessel. Reduce the mass to powder, and sublime it." *Dub.*

The *Edinburgh College* has given no formula for this preparation, having included it in the list of the Materia Medica.

Mercury and sulphur, when heated together, unite with great energy, and a product is obtained, which by sublimation becomes the red or bisulphuret of mercury. In order to render the combination more prompt, the sulphur is first melted; and the addition of the mercury should be made gradually, while the mixture is constantly stirred. Dr. Barker recommends the addition of the metal, by straining it upon the melted sulphur through a linen cloth, whereby it falls in the form of a shower, in a minutely divided state. When the temperature has arrived at a certain point, the combination takes place suddenly, with a slight explosion, and with the inflammation of the sulphur, which must be extinguished by covering the vessel. A black mass will thus be obtained, containing generally an excess of sulphur, which may be got rid of by gently heating the matter reduced to powder on a sand-bath. After this treatment it is better prepared for being sublimed, as directed by the Pharmacopœias. The sublimation is best performed, on a small scale, in a loosely stopped glass matrass, which should be placed in a crucible containing sand, and, thus arranged, exposed to a red heat. The equivalent quantities for forming this sulphuret, are 32.2 of sulphur, and 202 of mercury.

Preparation on the Large Scale. Cinnabar is seldom or never prepared on a small scale, being made in large quantities for the purposes of the arts; and on these accounts, it is, perhaps, preferably placed in the Materia Medica, as has been done by the Edinburgh College. In Holland, where it is principally manufactured, the sulphur is melted in a cast iron vessel, and the mercury is added in a divided state, by causing it to pass through chamois leather. As soon as the combination has taken place, the iron vessel is surmounted by another, into which the cinnabar is sublimed. In proportion as the quantity of the materials employed in one operation is greater, will the product have a finer tint. It is also important in the manufacture to use the materials pure, and to drive off any uncombined sulphur which may exist in the mass, before submitting it to sublimation.

Properties, &c. Red sulphuret of mercury is in the form of heavy, brilliant, crystalline masses, of a deep red colour and fibrous texture. It is inodorous and tasteless, and insoluble in water and alcohol. It is not acted on by sulphuric, nitric, or muriatic acid, nor by solutions of the caustic alkalies; but is decomposed by nitro-muriatic acid, the chlorine of which unites with its elements, so as to form corrosive sublimate, and chloride of sulphur. When heated in the open air, it is decomposed, the sulphur becoming sulphurous acid, and the mercury being volatilized. In close vessels, at a red heat, it sublimes without fusion, and condenses in a mass composed of a multitude of small needles. When duly levigated, it furnishes a powder of a brilliant red colour, and in this state constitutes the paint called *vermilion*. It occurs native, and forms the principal ore of mercury, and that from which the metal is exclusively extracted. It should not be purchased in powder; as, in that state, it is sometimes adulterated with red lead, dragon's blood, or chalk. If red lead be present, the cinnabar will not be entirely volatile at a red heat. Dragon's blood may be detected by alcohol, which will take up the colouring matter of this vegetable product, if present; and if chalk be mixed with it, effervescence will be excited on the addition of an acid. Red sulphuret of mercury is composed of one equiv. of mercury 202, and two of sulphur 32.2=234.2.

Medical Properties and Uses. Cinnabar was formerly considered to be alterative and anthelmintic, but is at present seldom or never given internally. It is sometimes employed in the way of fumigation, as a rapid sialagogue, in venereal ulcers of the nose and throat, in cases in which it is an object of importance to check the ulceration in the shortest time possible. The dose for internal exhibition is from ten grains to half a drachm, in the form of electuary or bolus. When used by fumigation, half a drachm may be thrown on a red-hot iron, and the fumes inhaled as they arise. These consist of sulphurous acid gas and mercury vapour, the former of which must prove highly irritating to the patient's lungs. A better material for mercurial fumigation is the black or gray protoxide of mercury. B.

HYDRARGYRUM AMMONIATUM. *U.S.* HYDRARGYRUM PRÆCIPITATUM ALBUM. *Lond.* HYDRARGYRI SUBMURIAS AMMONIATUM. *Dub.* *Ammoniated Mercury. White Precipitate.*

"Take of Corrosive Chloride of Mercury [Corrosive Sublimate] *half a pound;* Muriate of Ammonia *four ounces;* Solution of Carbonate of Potassa *half a pint;* Distilled Water *four pints.* Dissolve first the Muriate of Ammonia, then the Chloride of Mercury, in the Distilled Water, and add the Solution of Carbonate of Potassa. Wash the precipitate till it becomes tasteless, and then dry it." *U.S., Lond.*

"Add to the liquor which has been poured off from Precipitated Calomel, as much Water of Caustic Ammonia as may be sufficient completely to precipitate the metallic salt. Wash the precipitate with cold Distilled Water, and dry it on bibulous paper." *Dub.*

In the first of the above processes, the muriate of ammonia and corrosive sublimate being both dissolved in the distilled water, a very soluble double salt is formed in solution, formerly called *sal alembroth.* It may be obtained in crystals by evaporation, and is found to consist of one equiv. of corrosive sublimate and two equiv. of muriate of ammonia. When in solution, it may be considered as a compound of one equiv. of bipermuriate of mercury, and two of muriate of ammonia. Upon the addition of carbonate of potassa to this solution, the carbonic acid is given off, and the mercurial salt decomposed. Two equiv. of potassa combine with the two equiv. of muriatic acid, and remain in solution as muriate of potassa; while the one equiv. of peroxide of mercury precipitates in combination with one equiv. of muriate of ammonia to form the ammoniated mercury, the other equiv. of muriate of ammonia remaining in solution along with the muriate of potassa. This statement is made in accordance with the results of Mr. Hennel of London, who found the preparation under consideration on analysis to consist of one equiv. of peroxide of mercury 218, and one of muriate of ammonia 53.57=271.57. This composition is admitted by Berzelius; and the analysis of Guibourt, who makes the preparation an ammoniacal bichloride, combined with the ammoniaret of the peroxide of mercury, agrees virtually with that of Hennell; as it corresponds with two equiv. of the compound on Hennel's view, *minus* two equiv. of water.

The Dublin formula furnishes another mode of obtaining precisely the same compound, the nature of which has just been explained. The liquor which is poured off from precipitated calomel, consists, as was stated under that preparation, of a solution of corrosive sublimate which, in the dissolved state, is viewed as a bipermuriate of mercury. When ammonia is added to it, two equiv. of the alkali combine with the two equiv. of muriatic acid, and form two equiv. of muriate of ammonia; while the one equiv. of peroxide precipitates in combination with one of the equiv. of muriate of ammonia to form the ammoniated mercury. The process of the Dublin College is advantageous, in so far as it usefully employs the residuary liquor derived from another formula, and which would otherwise be lost. Indeed, it may be stated that the best way of making this preparation is to form an aqueous solution of corrosive sublimate, and to precipitate it with ammonia.

Properties, &c. Ammoniated mercury is a light, perfectly white powder, insoluble in water and alcohol, and having a taste, at first earthy and afterwards metallic. The caustic fixed alkalies unite with the muriatic acid, disengage the ammonia, and set the peroxide free. When exposed to heat it is decomposed, and resolved into water, nitrogen, ammonia, and protochloride of mercury or calomel. If adulterated with white lead or chalk, the fraud may be detected by exposing a sample of the preparation to a strong red heat, when these impurities will remain. Should starch be mixed with it, a charry residuum will be obtained on the application of heat. The nature of this preparation was long involved in doubt; and admitting the composition assigned to it by Mr. Hennell, it is not easy to give it a name which will accurately express its constituents. Under these circumstances, perhaps, the name given to it in the U. S. Pharmacopœia is as little liable to objection as any other that could be selected; and it has in its favour the precedent of the analogous names of *ammoniated copper* and *ammoniated iron.*

Medical Properties and Uses. Ammoniated mercury is used only in the form of ointment as an external application.

Off. Prep. Unguentum Hydrargyri Ammoniati, *U. S., Lond., Dub.* B.

HYDRARGYRUM CUM CALCIS CARBONATE. *U.S.* HYDRARGYRUM CUM CRETA. *Lond., Dub. Mercury with Carbonate of Lime. Mercury with Chalk.*

"Take of Purified Mercury *three ounces;* Prepared Carbonate of Lime [Prepared Chalk, *Lond.*] *five ounces.* Rub them together till all the globules disappear." *U.S., Lond.*

The *Dublin College* prepares it in the same manner as *Mercury with Magnesia,* only substituting precipitated carbonate of lime for carbonate of magnesia.

When mercury is triturated with certain dry and pulverulent substances, such as chalk or magnesia, it gradually loses its fluidity and metallic lustre, and assumes the form of a blackish or dark gray powder. A similar change takes place when it is rubbed with viscid or greasy substances, such as honey or lard. The globules in either case entirely disappear, so as not to be visible even through a good lens; and the mercury is said to be extinguished. It was formerly thought that the metal was oxidized in the process, and that the medical activity of the preparation depended on the presence of the black or protoxide of mercury. At present, however, the change is generally attributed solely to the mechanical division of the metal, which in this state is supposed to be capable of acting on the system. In relation to the preparation under consideration, Mr. Phillips observes, that the mercury is wholly insoluble in acetic acid, and therefore is not in the state of protoxide. He suggests, however, that it may be in the form of a suboxide; as, when the chalk has been separated by acetic acid, the mercury does not form a fluid mass, but exists in separate and minute globules.

Medical Properties and Uses. This preparation is a very mild mercurial, similar in its properties to the blue pill, but much weaker. It is sometimes used as an alterative, particularly in the complaints of children, attended with deficient biliary secretion, indicated by white or clay-coloured stools. The chalk is antacid, and, though in small quantity, may sometimes be a useful accompaniment of the mercury in diarrhœa. Eight grains of the preparation, according to the U.S. and London Pharmacopœias, contain three grains of mercury. The dose is from five grains to half a drachm twice a day. W.

HYDRARGYRUM CUM MAGNESIA. *Dub. Mercury with Magnesia.*

"Take of Purified Mercury, Manna, each, *two parts;* Carbonate of Magnesia *one part.* Rub the Mercury with the Manna in an earthenware mortar, dropping in sufficient water to give to the mixture the consistence of syrup, and continue the trituration till the globules disappear. Then add, still rubbing, an eighth part of the Carbonate of Magnesia; and when this is well mixed with the other ingredients, add sixteen parts of hot water, and agitate the mixture. Let this stand for some time that the sediment may subside, and then decant the fluid. Repeat the washing twice, that the whole of the Manna may be removed; and with the sediment, while it is still moist, mix the remainder of the Carbonate of Magnesia. Lastly, dry the powder on bibulous paper." *Dub.*

The use of the manna in this process is merely to facilitate the extinction of the mercury, as it is wholly washed away, and the metal is left mixed with magnesia. The preparation has the same virtues with the preceding, but may be preferably used in the complaints of children attended with constipation. W.

INFUSA.

Infusions.

These are aqueous solutions obtained by treating with water, without the aid of ebullition, vegetable products which are only partly soluble in that liquid. The water employed may be hot or cold according to the objects to be accomplished. Infusions are generally prepared by pouring boiling water upon the vegetable substance, and macerating in a lightly closed vessel till the liquid cools. The soluble principles are thus extracted more rapidly, and, as a general rule, in larger proportion than at a lower temperature. Some substances, moreover, are dissolved in this manner, which are nearly or quite insoluble in cold water. A prolonged application of heat is in some instances desirable; and this may be effected by placing the vessel near the fire. Cold water is preferred, when the active principle is highly volatile, or when any substance of difficult solubility at a low temperature exists in the vegetable, which it is desirable to avoid in the infusion. A longer continuance of the maceration is necessary in this case; and, in warm weather, there is sometimes danger that spontaneous decomposition may commence before the process is completed. The water employed should be free from saline impurities, which frequently produce precipitates, and render the infusion turbid. Fresh river, rain, or distilled water is usually preferable to that of pumps or springs.

The substance to be acted on should be sliced or bruised, or employed in the state of powder; but this last condition is seldom requisite, and is always inconvenient, as it requires that the infusion should be filtered through paper in order completely to separate the undissolved portion. In other cases, it is sufficient to strain through fine linen. Infusions are usually prepared in glazed earthenware or porcelain vessels fitted with covers. Mr. Brande suggests the use of clean metallic vessels, which when finely polished retain the heat for a greater length of time; but they are also more liable to chemical alteration, and may sometimes injuriously affect the preparation.

As infusions do not keep well, especially in warm weather, they should be made extemporaneously and in small quantities. In this country they are usually prepared in families, and the propriety of their introduction into the Pharmacopœia has been doubted; but it is desirable to have certain fixed standards for the convenience of the medical practitioner; and it is sometimes convenient to direct infusions from the apothecary, for whose guidance officinal formulæ are necessary. Physicians would, indeed, find their advantage in more frequently directing them from the shops, instead of leaving their preparation to the carelessness or want of skill of the attendants upon the sick.

As we have already treated of the chemical relations and medical properties of the substances used in infusion, it would be useless repetition to enlarge upon these points in the following details. We shall touch upon them only in cases of peculiar interest, or where changes requiring particular notice may grow out of the nature of the process. W.

INFUSUM ANGUSTURÆ. *U. S., Dub.* INFUSUM CUSPARIÆ. *Lond. Infusion of Angustura Bark.*

"Take of Angustura Bark, bruised, *half an ounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

The *London* and *Dublin Colleges* direct two drachms to half a pint, and proceed as above.

The dose of the infusion is two fluidounces repeated every two, three, or four hours. W.

INFUSUM ANTHEMIDIS. *U. S., Lond.* INFUSUM ANTHEMIDIS NOBILIS. *Ed.* INFUSUM CHAMÆMELI. *Dub.* *Infusion of Chamomile.*

"Take of Chamomile *half an ounce;* Boiling Water *a pint.* Macerate for ten minutes in a covered vessel, and strain." *U. S.*

The *London College* orders two drachms of the flowers to half a pint of boiling water, and proceeds as above; the *Edinburgh* directs two drachms to eight ounces of cold water, and macerates for twenty-four hours; the *Dublin* agrees with the London in the proportion of the ingredients, and with the Edinburgh in the period of digestion.

The infusion of chamomile has the odour and taste of the flowers. It affords precipitates with gelatin, yellow Peruvian bark, sulphate of iron, tincture of muriate of iron, nitrate of silver, corrosive chloride of mercury, and the acetates of lead. (*London Dispensatory.*) As a tonic it is given cold in the dose of two fluidounces several times a day. To assist the operation of emetic medicines it should be administered in the tepid state, and in large draughts. The infusion prepared by maceration in cold water is more grateful to the palate and stomach than that made with boiling water, but is less efficient as an emetic. W.

INFUSUM ARMORACIÆ. *U. S.* INFUSUM ARMORACIÆ COMPOSITUM. *Lond., Dub.* *Infusion of Horse-radish.*

"Take of Horse-radish [fresh root], sliced, Mustard [seed], bruised, each, *an ounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel and strain." *U.S.*

The *London College* adds to the infusion, prepared as above directed, a fluidounce of the compound spirit of horse-radish. The process of the *Dublin College* differs from that of the London only in requiring a maceration of six instead of two hours.

This infusion is rendered turbid by the deposition of vegetable albumen, and in warm weather speedily runs into the putrefactive fermentation. It affords precipitates with the infusion of galls and of Peruvian bark, with the alkaline carbonates, nitrate of silver, and corrosive chloride of mercury. (*London Dispensatory.*) It has the stimulant properties of its two active ingredients, and is occasionally used in paralytic and dropsical affections attended with general debility. The dose is about two fluidounces three or four times a day. W.

INFUSUM AURANTII COMPOSITUM. *Lond., Dub.* *Compound Infusion of Orange Peel.*

"Take of Dried Orange Peel *two drachms;* fresh Lemon Peel *a drachm;* Cloves, bruised *half a drachm;* Boiling Water *half a pint.* Macerate for a quarter of an hour in a covered vessel, and strain." *Lond., Dub.*

This infusion is given as a grateful stomachic in the dose of two or three fluidounces. W.

INFUSUM BUCHU. *Dub.* *Infusion of Buchu.*

"Take of Buchu Leaves *half an ounce;* Boiling Water *half a pint.* Digest for four hours, and strain through linen." *Dub.*

This infusion has the odour and taste, and the medical virtues of the leaves; and affords a convenient mode of administering the medicine. The dose is one or two fluidounces. W.

INFUSUM CARYOPHYLLORUM. *Lond., Dub.* *Infusion of Cloves.*

"Take of Cloves, bruised, *a drachm;* Boiling Water *half a pint.* Macerate for two hours in a covered vessel, and strain." *Lond., Dub.*

The infusion of cloves affords precipitates with lime-water, and with the soluble salts of iron, zinc, lead, silver, and antimony. (*Phillips.*) The dose is about two fluidounces. W.

INFUSUM CASCARILLÆ. *U.S., Lond., Dub.* *Infusion of Cascarilla.*

"Take of Cascarilla, bruised, *an ounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U.S.*

The *London* and *Dublin Colleges* direct half an ounce of the bark to half a pint of boiling water, and proceed as above.

This infusion affords precipitates with lime-water, infusion of galls, nitrate of silver, acetate and subacetate of lead, sulphate of zinc, and sulphate of iron. (*London Dispensatory.*) The medium dose is two fluidounces. W.

INFUSUM CATECHU COMPOSITUM. *Lond., Dub.* INFUSUM ACACIÆ CATECHU. *Ed.* *Compound Infusion of Catechu.*

"Take of Extract of Catechu *two drachms and a half;* Cinnamon Bark, bruised, *half a drachm;* Boiling Water *half a pint.* Macerate for an hour in a covered vessel, and strain." *Lond.* "Digest for an hour in a covered vessel, and strain through linen." *Dub.*

The *Edinburgh College* orders the same quantities of catechu and cinnamon, but directs them to be macerated in seven ounces of boiling water for two hours, and an ounce of simple syrup to be added to the strained infusion.

This is an elegant mode of administering catechu. The dose is from one to three fluidounces, repeated three or four times a day, or more frequently. W.

INFUSUM CINCHONÆ. *U. S., Lond. Dub.* INFUSUM CINCHONÆ LANCIFOLIÆ. *Ed.* *Infusion of Peruvian Bark.*

"Take of Peruvian Bark, bruised, *an ounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U.S.*

"Take of Bark of the Cinchona lancifolia [pale bark], bruised, *half an ounce;* Boiling Water *half a pint.* Macerate for two hours in a lightly covered vessel, and strain." *Lond.*

"Take of Bark of the Cinchona lancifolia, in powder, *an ounce;* Water [cold] *a pound.* Macerate for twenty-four hours in a lightly covered vessel, with occasional agitation, and filter." *Ed.*

"Take of Bark of the Cinchona lancifolia, in coarse powder, *an ounce;* Cold Water *twelve fluidounces.* Triturate the Bark with a little of the Water, and add the remainder during the trituration. Macerate for twenty-four hours, with frequent agitation, and decant the clear liquor." *Dub.*

We can discover no good reason for the exclusive employment by the British Colleges of the pale bark in the preparation of this infusion. The U.S. Pharmacopœia, wisely we think, leaves the particular variety to the choice of the physician.

Though the infusion with boiling water, as directed by the U.S. and London Pharmacopœias, is more quickly prepared than the cold infusion of the Edinburgh and Dublin Colleges, and therefore better adapted to cases of emergency, yet the latter is a more elegant preparation, not turbid like the former, and at least equally efficient. The trituration directed by the Dublin College facilitates the process, by thoroughly wetting the powder, and thus enabling it to be more readily diffused through the liquid. We have been much in the habit of using the cold infusion prepared with the addition of a fluidrachm of aromatic sulphuric acid to the ingredients, and have found it very effectual. The addition of the acid ensures the solution of all or nearly all the quinia and cinchonia. We have always preferred the red bark, as abounding most in the active principles.

The former edition of the U.S. Pharmacopœia directed three other infusions of cinchona, one with lime-water, a second with magnesia, and a third with lemon-juice. Of these, the first two are obviously improper preparations; as the lime and magnesia decompose the salts of quinia and cinchonia, and precipitate the alkaline bases. In the third, on the contrary, the lemon-juice promotes the solubility of the active principles, and is therefore a useful addition, though, as it is not always applicable, it may, with propriety be left to extemporaneous prescription. These preparations have been omitted in the last edition.

The infusion of cinchona affords precipitates with the alkalies, alkaline carbonates, and alkaline earths; the soluble salts of iron, zinc, and silver; corrosive chloride of mercury, arsenious acid, and tartar emetic; gelatinous solutions; and various vegetable infusions and decoctions, as those of galls, chamomile, columbo, cascarilla, horse-radish, cloves, catechu, orange-peel, foxglove, senna, rhubarb, valerian, and simaruba. In some instances the precipitate occurs immediately, in others not for several hours. (*London Dispensatory.*) Few, however, of these substances diminish the efficacy of the infusion, as they do not affect the active principles. The alkalies, alkaline earths, and vegetable astringents are really incompatible. The same is said to be the case with tartaric and oxalic acids, and the soluble tartrates and oxalates.

The infusion of cinchona may be advantageously administered in cases which require tonic treatment, but do not call for the full powers of the bark. The medium dose is two fluidounces to be repeated three or four times a day, or more frequently in acute diseases. W.

INFUSUM COLOMBÆ. *U.S., Ed., Dub.* INFUSUM CALUMBÆ. *Lond.* *Infusion of Columbo.*

"Take of Columbo, sliced, *half an ounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U.S.*

The *London* and *Dublin Colleges* direct two drachms of columbo to half a pint of boiling water; the *Edinburgh*, one drachm to eight ounces; and all proceed as above.

This infusion is not disturbed by the salts of iron, and may be conveniently administered in connexion with them. It very soon spoils. The dose is two fluidounces three or four times a day. W.

INFUSUM DIGITALIS. *U.S., Lond., Dub.* INFUSUM DIGITALIS PURPUREÆ. *Ed.* *Infusion of Foxglove.*

"Take of Foxglove [dried leaves] *a drachm;* Boiling Water *half a pint;* Tincture of Cinnamon *a fluidounce.* Macerate the Foxglove with the Water for four hours in a covered vessel, and strain; then add the Tincture of Cinnamon." *U.S.*

The *London* and *Dublin* processes correspond with the above, except that half a fluidounce of the *spirit* of cinnamon is employed instead of a fluidounce of the *tincture.* The *Edinburgh College* takes a drachm of the leaves, eight ounces of boiling water, and an ounce of the spirit of cinnamon; and having macerated the leaves in the water for four hours, adds the spirit, and strains.

This infusion is essentially the same with that employed by Withering. It affords precipitates with the sulphate of iron, acetate of lead, and infusion of Peruvian bark. (*London Dispensatory.*) The dose is half a fluidounce, repeated twice a day under ordinary circumstances, every eight hours in urgent cases, until the system is affected. W.

INFUSUM EUPATORII PERFOLIATI. *U.S. Infusion of Thoroughwort.*

"Take of Thoroughwort [the dried herb] *an ounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U.S.*

As a tonic, this infusion should be taken cold in the dose of two fluidounces three or four times a day, or more frequently; as an emetic and diaphoretic, in large tepid draughts. W.

INFUSUM GENTIANÆ COMPOSITUM. *U.S., Lond., Ed., Dub. Compound Infusion of Gentian.*

"Take of Gentian, bruised, *half an ounce;* Orange Peel [dried peel of the Seville orange], bruised, Coriander, bruised, each, *a drachm;* Diluted Alcohol *four fluidounces;* Water [cold] *twelve fluidounces.* First pour on the Alcohol, and three hours afterwards, the Water; then macerate for twelve hours, and strain." *U.S.*

The above was copied from the *Edinburgh* formula, which differs only in designating the quantity of diluted alcohol and of water in troy ounces instead of fluidounces.

The *London* and *Dublin Colleges* employ the following formula. "Take of Gentian Root, sliced, Dried Orange Peel, each, *a drachm;* Fresh Lemon Peel *two drachms* [*one drachm*, Dub.]; Boiling Water *twelve fluidounces.* Macerate for an hour in a lightly covered vessel, and strain."

The U.S. and Edinburgh infusion differs materially from the London and Dublin. The former has three times as much gentian in proportion to the solvent as the latter, and is therefore a much stronger bitter; while, by the use of cold instead of boiling water, less of the inert mucilaginous matter is extracted. The use of the diluted alcohol is to assist in dissolving the bitter principle, and at the same time to contribute towards the preservation of the infusion, which, without this addition, is very apt to spoil. The preparation, however, may be considered rather in the light of a very weak tincture than of an infusion, and should be used accordingly.

The dose of the infusion of the U.S. Pharmacopœia is a fluidounce, that of the preparation of the London College two or three fluidounces, to be repeated three or four times a day. W.

INFUSUM LINI. *U.S.* INFUSUM LINI COMPOSITUM. *Lond., Dub.* INFUSUM LINI USITATISSIMI. *Ed. Infusion of Flaxseed.*

"Take of Flaxseed *half an ounce;* Liquorice Root, bruised, *two drachms;* Boiling Water *a pint.* Macerate for four hours in a covered vessel, and strain." *U. S.*

The *London* and *Dublin Colleges* direct an ounce of flaxseed, *bruised,* half an ounce of liquorice root, *sliced,* and two pints of boiling water; the *Edinburgh,* an ounce of flaxseed, two drachms of liquorice root, *bruised,* and two pounds of boiling water; all complete the process in the manner directed in the U.S. Pharmacopœia.

This is a useful demulcent drink in inflammatory affections of the mucous membrane of the lungs and urinary passages. It may be taken *ad libitum.* W.

INFUSUM MENTHÆ SIMPLEX. *Dub.* *Simple Infusion of Mint.*

"Take of the Dried Leaves of Spearmint *two drachms;* Boiling Water a sufficient quantity to afford *six ounces* [fluidounces] of strained liquor." *Dub.*

This is common mint tea, and may be taken *ad libitum.* W.

INFUSUM MENTHÆ COMPOSITUM. *Dub.* *Compound Infusion of Mint.*

"Take of the Dried Leaves of Spearmint *two drachms;* Boiling Water a sufficient quantity to afford *six ounces* [fluidounces] of strained liquor. Digest for half an hour in a covered vessel, and strain the liquor when cold; then add, of Refined Sugar *two drachms,* Oil of Spearmint *three drops* dissolved in *half an ounce* [fluidounce] of Compound Tincture of Cardamom." *Dub.*

This is an agreeable aromatic infusion, useful in allaying nausea and vomiting, and affording an eligible vehicle for unpleasant medicines. The dose is one or two fluidounces frequently repeated. W.

INFUSUM PRUNI VIRGINIANÆ. *U.S.* *Infusion of Wild-cherry Bark.*

"Take of Wild-cherry Bark, bruised; *half an ounce;* Water [cold] *a pint.* Macerate for twelve hours, and strain." *U.S.*

This is a useful addition to the infusions first adopted as officinal in the former edition of the U.S. Pharmacopœia. It is a peculiarly suitable object for officinal direction, as, in consequence of the volatile nature of one of its active ingredients, it is better prepared with cold water than in the ordinary mode. The period of maceration might with propriety be extended to twenty-four hours, or even longer in cold weather. The infusion, which is beautifully transparent, has the colour of Madeira wine, and the pleasant bitterness and peculiar flavour of the bark. The dose is two or three fluidounces three or four times a day, or more frequently when a strong impression is required. W.

INFUSUM QUASSIÆ. *U.S., Lond., Dub.* INFUSUM QUASSIÆ EXCELSÆ. *Ed.* *Infusion of Quassia.*

"Take of Quassia, rasped, *two drachms;* Water [cold] *a pint.* Macerate for twelve hours, and strain." *U.S.*

The *London* and *Dublin Colleges* order a scruple of quassia, half a pint of *boiling water,* and maceration for two hours in a covered vessel. The *Edinburgh College* proceeds in the same way, employing half a drachm of quassia and eight ounces of boiling water.

The proportion of quassia directed in the British Pharmacopœias is much too small. The infusion of the London and Dublin Colleges contains the strength of only two grains and a half of quassia in a fluidounce, that of the Edinburgh College, three grains and three-quarters in an ounce; while the dose of quassia in substance is from twenty grains to a drachm, and of the extract not less than five grains. We, therefore, prefer the proportions directed by our national Pharmacopœia. Boiling water may be employed when it is desirable to obtain the preparation quickly; but cold water affords a clearer infusion. The dose is two fluidounces three or four times a day. W.

INFUSUM RHEI. *U.S., Lond., Ed., Dub.* *Infusion of Rhubarb.*

"Take of Rhubarb, sliced, *a drachm;* Boiling Water *half a pint.* Macerate for two hours in a covered vessel, and strain." *U.S., Lond., Dub.*

"Take of Russian Rhubarb, bruised, *half an ounce;* Boiling Water *eight ounces;* Spirit of Cinnamon *an ounce.* Macerate the Rhubarb with the Water, in a close vessel, for twelve hours; then add the Spirit, and strain." *Ed.*

In the latter process there is a great waste of a costly medicine, the Russian Rhubarb commanding a very high price. We greatly prefer the first formula. In order, however, that the rhubarb may be exhausted, the maceration should be conducted near the fire at a temperature somewhat less than that of boiling water. It is customary to add some aromatic, such as cardamom, fennel-seed, or nutmeg, which improves the taste of the infusion, and renders it more acceptable to the stomach. One drachm of either of these spices may be digested in connexion with the rhubarb.

This infusion may be given as a gentle laxative, in the dose of one or two fluidounces, every three or four hours, till it operates. It is occasionally used as a vehicle of tonic, antacid, or more active cathartic medicines. The stronger acids, and most metallic solutions, are incompatible with it. W.

INFUSUM ROSÆ COMPOSITUM. *U.S., Lond.* INFUSUM ROSÆ GALLICÆ. *Ed.* INFUSUM ROSÆ ACIDUM. *Dub.* *Compound Infusion of Roses.*

"Take of Red Roses [dried petals] *half an ounce;* Boiling Water *two pints and a half;* Diluted Sulphuric Acid *three fluidrachms;* Sugar [refined] *an ounce and a half.* Pour the Water upon the Roses in a glass vessel; then add the Acid, and macerate for half an hour; lastly, strain the liquor and add the Sugar." *U.S., Lond.*

The *Dublin* process corresponds with the above, except that the petals are directed without their claws, and three pints of water are employed instead of two pints and a half. The *Edinburgh College* directs an ounce of the dried petals, two pounds and a half of boiling water, half an ounce of sulphuric acid, and an ounce of white sugar; macerates the petals with the water for four hours in an earthen vessel not glazed with lead; then adds the acid, and having strained the liquor, dissolves the sugar in it.

The red roses serve little other purpose than to impart a fine red colour and a slight astringent flavour to the preparation, which owes its medicinal virtues almost exclusively to the sulphuric acid. It is refrigerant and astringent, and affords a useful and not unpleasant drink in hemorrhages and colliquative sweats. It is much used by British practitioners as a vehicle for saline medicines; particularly sulphate of magnesia, the taste of which it serves to cover. It is also employed as a gargle, usually in connexion with acids, nitre, alum, or tincture of Cayenne pepper. The dose is from two to four fluidounces. W.

INFUSUM SARSAPARILLÆ COMPOSITUM. *Dub.* *Compound Infusion of Sarsaparilla.*

"Take of Sarsaparilla Root, previously cleansed with cold water and sliced, *an ounce;* Lime-water *a pint.* Macerate for twelve hours in a covered vessel, with occasional agitation, and strain." *Dub.*

From the experiments of M. Soubeiran it appears, that, by maceration in cold water for twenty-four hours, the active principle of sarsaparilla is extracted as effectually as by infusion in boiling water and digestion for two hours, and that in either case the infusion is stronger than the decoction; but the aqueous preparation which he found to possess most of the sensible properties of the root, was made by infusing in water the spirituous extract obtained according to the process of M. Beral. (See page 842.) In all his experiments, M. Soubeiran employed the same proportions of the root and of water. (*Journ. de Pharm.* xvi. 43.) A cold infusion of sarsaparilla may be considered an eligible preparation; but no advantage can result from the use of lime-water, as directed by the Dublin College. From two to four fluidounces of the infusion may be taken three times a day. W.

INFUSUM SENNÆ. *U.S.* INFUSUM SENNÆ COMPOSITUM. *Lond., Dub.* INFUSUM CASSIÆ SENNÆ. *Ed.* *Infusion of Senna.*

"Take of Senna *an ounce;* Coriander [seed], bruised, *a drachm;* Boiling Water *a pint.* Macerate for an hour in a covered vessel, and strain." *U.S.*

The *London College* orders an ounce and a half of senna, a drachm of sliced ginger-root, and a pint of boiling water; the *Edinburgh*, six drachms of senna, a scruple of ginger, and nine ounces of boiling water; and the *Dublin*, an ounce of senna, a drachm of ginger, and a pint of boiling water; all macerate as above directed.

We decidedly prefer the formula of the U.S. Pharmacopœia. The proportions of senna directed by the London and Edinburgh Colleges, are unnecessarily and wastefully large; and coriander is a better addition than ginger to an infusion very often given in inflammatory affections. This infusion deposites, on exposure to the air, a yellowish precipitate, which is said to aggravate its griping tendency; it should, therefore, not be made in large quantities. It is customary to connect with it manna and some one of the neutral salts, which both increase its efficacy and render it less painful in its operation. The following is a good formula for the preparation of senna tea. Take of senna *half an ounce;* sulphate of magnesia, manna, each, *an ounce;* fennel seed *a drachm;* boiling water *half a pint.* Macerate in a covered vessel till the liquid cools. One-third may be given for a dose, and repeated every four or five hours till it operates.

The dose of the infusion of the U.S. Pharmacopœia is about four fluidounces. W.

INFUSUM SENNÆ CUM TAMARINDIS. *Dub.* INFUSUM SENNÆ COMPOSITUM. *Ed.* *Infusion of Senna with Tamarinds.*

"Take of Preserved Tamarinds *an ounce;* Senna Leaves *a drachm;* Coriander Seeds, bruised, *a drachm;* Brown Sugar *half an ounce;* Boiling Water *eight ounces.* Macerate for four hours, with occasional agitation, in a closed earthen vessel, not glazed with lead, and strain.

"It may also be made with double, triple, &c, the quantity of senna." *Ed.*

The process of the *Dublin College* corresponds closely with the above. In this infusion, the unpleasant taste of the senna is covered by the acidity of the tamarinds and sweetness of the sugar. It is aperient and refrigerant, and is well adapted to febrile complaints when a laxative operation is desired. The dose is from two to four fluidounces. W.

INFUSUM SERPENTARIÆ. *U.S.* *Infusion of Virginia Snakeroot.*

"Take of Virginia Snakeroot *half an ounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U.S.*

The proportion of serpentaria in this infusion, as directed in the first edition of the U.S. Pharmacopœia, was twice as great as that now ordered; but it may be doubted whether the preparation was much stronger. A pint of water does not extract all the virtues of an ounce of the root, at least in the time specified by the Pharmacopœia. The infusion, as at present directed, is quite strong enough. The dose is one or two fluidounces, repeated every two hours in low forms of fever, but less frequently in chronic affections. W.

INFUSUM SIMAROUBÆ. *Lond.* INFUSUM SIMARUBÆ. *Dub.* *Infusion of Simaruba.*

"Take of Simaruba Bark, bruised, *half a drachm;* Boiling Water *half a pint.* Macerate for two hours in a covered vessel, and strain." *Lond., Dub.*

This is a feeble preparation, and little, if at all used in the United States. The dose is two fluidounces. W.

INFUSUM SPIGELIÆ. *U.S.* *Infusion of Pink-root.*

"Take of Pink-root *half an ounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U.S.*

The dose of this infusion for a child two or three years old, is from four fluidrachms to a fluidounce; for an adult, from four to eight fluidounces, repeated morning and evening. A quantity of senna equal to that of the spigelia, is usually added in order to ensure a cathartic effect. W.

INFUSUM TABACI. *U.S., Lond., Dub.* *Infusion of Tobacco.*

"Take of Tobacco *a drachm;* Boiling Water *a pint.* Macerate for an hour in a covered vessel, and strain." *U.S., Lond., Dub.*

This is used only in the form of enema in strangulated hernia, obstinate colic, and retention of urine from spasm of the urethra. Only half of the pint should be employed at once; and if this should not produce relaxation in half an hour, the remainder may be injected. Fatal consequences have resulted from too free a use of tobacco in this way. W.

INFUSUM ULMI. *U.S.* *Infusion of Slippery Elm Bark.*

"Take of Slippery Elm Bark, sliced, *an ounce;* Boiling Water *a pint.* Macerate for twelve hours in a covered vessel, and strain." *U.S.*

The period of maceration is unnecessarily long, unless cold water is employed. This infusion may be used *ad libitum*, as a demulcent and nutritious drink in catarrhal and nephritic diseases, and in inflammatory affections of the intestinal mucous membrane. W.

INFUSUM VALERIANÆ. *U.S., Dub.* *Infusion of Valerian.*

"Take of Valerian *half an ounce;* Boiling Water *a pint.* Macerate for an hour in a covered vessel, and strain." *U.S.*

The *Dublin College* directs two drachms of valerian, in coarse powder, seven fluidounces of boiling water, digestion for an hour, and straining after the liquid has become cold.

The dose of this infusion is two fluidounces, repeated three or four times a day, or more frequently. W.

* * *

LINIMENTA.

Liniments.

These are preparations intended for external use, of such a consistence as to render them conveniently applicable to the skin by gentle friction with the hand. They are usually thicker than water, but thinner than the ointments; and are always liquid at the temperature of the body.

LINIMENTUM AMMONIÆ. *U.S., Dub.* LINIMENTUM AMMONIÆ FORTIUS. *Lond.* OLEUM AMMONIATUM. *Ed.* *Liniment of Ammonia.*

"Take of Water of Ammonia *half a fluidounce;* Olive Oil *two fluidounces.* Mix them." *U.S.*

The *London College* directs a fluidounce of "Solution of Ammonia" to two fluidounces of olive oil; the *Edinburgh*, one part of "Water of Ammonia" to eight parts of olive oil; the *Dublin*, two fluidrachms of "Water of Caustic Ammonia" to two fluidounces of the oil.

The proportions of the alkali to the oil, directed by the several Pharmacopœias, though very different, are not so much so in reality as they appear to be; the water of ammonia being strongest in those instances where the quantity is least. In our Pharmacopœia, a mean proportion between the two extremes has been wisely adopted. In this preparation, the ammonia unites with the oil to form a soap, which is partly dissolved, partly suspended in the water, producing a white opaque emulsion. This liniment is an excellent rubefacient, frequently employed in inflammatory affections of the throat, catarrhal and other pectoral complaints of children, and in rheumatic pains. It is applied by rubbing it gently upon the skin, or placing a piece of flannel saturated with it over the affected part. Should it occasion too much inflammation, as sometimes happens, it must be diluted with oil. W.

LINIMENTUM AMMONIÆ SUBCARBONATIS. *Lond.* *Liniment of Subcarbonate of Ammonia.*

"Take of Solution of Subcarbonate of Ammonia *a fluidounce;* Olive Oil *three fluidounces.* Shake them together until they unite." *Lond.*

In this instance, as in the preceding, a kind of fluid soap is formed; but the union between the oil and alkali is less perfect, and after a short time the soapy matter separates from the water. The preparation is therefore less elegant; and as the end which it was probably intended to answer of affording a milder rubefacient, may be obtained by diluting the liniment of ammonia with olive oil, there seems to be no good reason for retaining it among the officinal remedies. W.

LINIMENTUM CALCIS. *U.S., Dub.* OLEUM LINI CUM CALCE, sive LINIMENTUM AQUÆ CALCIS. *Ed.* *Liniment of Lime.*

"Take of Lime-water, Flaxseed Oil, each, *a fluidounce.* Mix them." *U. S.*

The *Edinburgh College* directs equal parts of the same ingredients; the *Dublin*, three fluidounces of lime-water, and three fluidounces of olive oil.

The lime forms a soap with the oil, of which there is a great excess, that separates upon standing. Olive oil, as directed by the Dublin College, is often substituted for that of flaxseed; but possesses no other advantage over it than that of having a less unpleasant odour. This is a very useful liniment in recent burns and scalds. It is sometimes called *Carron oil*, from having been much employed at the iron works of that name in Scotland. W.

LINIMENTUM CAMPHORÆ. *U.S. Lond.* OLEUM CAMPHORATUM. *Ed., Dub.* *Camphor Liniment.*

"Take of Camphor *half an ounce;* Olive Oil *two fluidounces.* Dissolve the Camphor in the Oil." *U.S., Lond.*

The *Edinburgh* and *Dublin Colleges* direct one part of camphor to eight of olive oil.

This is employed as an anodyne embrocation in sprains, bruises, rheumatic or gouty affections of the joints, and other local pains. It is also supposed to have a discutient effect when rubbed upon glandular swellings. W.

LINIMENTUM CAMPHORÆ COMPOSITUM. *Lond., Dub. Compound Camphor Liniment.*

"Take of Camphor *two ounces;* Solution of Ammonia *six fluidounces;* Spirit of Lavender *a pint.* Mix the Solution of Ammonia with the Spirit in a glass retort; then, with a gentle heat, distil a pint; lastly, dissolve the Camphor in the distilled liquor." *Lond., Dub.*

This preparation deserves a place rather among the Spirits or Tinctures than the Liniments. The distillation is an unnecessary refinement, as the ingredients may be immediately united; and the quantity of water contained in the solution of ammonia cannot materially diminish the efficacy of the liniment. Indeed, if prepared with the water of ammonia of the U.S. Pharmacopœia, it would be too stimulant without dilution. It is used as a rubefacient, and at the same time anodyne embrocation, in local pains, particularly of a rheumatic character. W.

LINIMENTUM CANTHARIDIS. *U.S. Liniment of Spanish Flies.*

"Take of Spanish Flies, in powder, *an ounce;* Oil of Turpentine *half a pint.* Digest for three hours in a water-bath, and strain." *U.S.*

The oil of turpentine is an excellent solvent of the active principle of cantharides, and when impregnated with it, acquires in addition to its own rubefacient properties, those of a powerful epispastic. In the first edition of the Pharmacopœia, the directions were to simmer for three hours; but as the flies are injured by a heat above that of boiling water, the use of the water-bath is now ordered. This liniment was introduced into notice by Dr. Joseph Hartshorne of Philadelphia, who employed it with great advantage as an external stimulant in the prostrate states of typhus fever. Caution, however, is necessary in its use, both to graduate its strength to the circumstances of the case, and not to apply it very extensively, lest it may produce severe and troublesome, if not dangerous vesication. (See *Eclectic Repertory*, vol. i. p. 94.) If too powerful in its undiluted state, it may be weakened by the addition of olive or linseed oil. W.

LINIMENTUM HYDRARGYRI. *Lond. Liniment of Mercury.*

"Take of Stronger Mercurial Ointment, Prepared Lard, each *four ounces;* Camphor *an ounce;* Rectified Spirit *fifteen minims;* Solution of Ammonia *four fluidounces.* Rub the Camphor first with the Spirit, then with the Lard and Mercurial Ointment; lastly, add gradually the Solution of Ammonia, and mix the whole." *Lond.*

This is a stimulant liniment, employed for the discussion of chronic glandular swellings and venereal tumours, and to promote the absorption of collections of fluid. It is said to be more apt to salivate than mercurial ointment. One drachm of it is to be rubbed upon the affected part night and morning. W.

LINIMENTUM SAPONIS CAMPHORATUM. *U.S. Camphorated Soap Liniment. Opodeldoc.*

"Take of Common Soap *three ounces;* Camphor *an ounce;* Oil of Rosemary, Oil of Origanum, each, *a fluidrachm;* Alcohol *a pint.* Dissolve the Camphor and Oils in the Alcohol; then add the Soap, and digest, by means of a sand-bath, till it is dissolved. This Liniment, when cold, is of the consistence of a soft ointment." *U.S.*

This preparation is directed only by the U.S. Pharmacopœia. It differs from the common soap liniment (*Tinctura Saponis Camphorata*) chiefly in being prepared with common white soap, made with animal fat, instead of Castile soap, which is made with olive oil. The latter will not coagulate upon cooling like the former, and is therefore unfit for the preparation of this liniment, which is intended to be in the solid state. It is customary, after the solution of the soap has been effected, to pour the liquid into small wide-mouthed glass bottles, containing about four fluidounces, in which it solidifies into a soft, semitransparent, uniform, yellowish-white mass. This liniment melts with the heat of the body, and therefore becomes liquid when rubbed upon the skin. It is much used, under the common name of *opodeldoc*, as an anodyne application in sprains, bruises, and rheumatic pains.

LINIMENTUM SIMPLEX. *Ed.* *Simple Liniment.*

"Take of Olive Oil *four parts;* White Wax *one part.* Melt the Wax in the Oil with a gentle heat, then stir the mixture well till it becomes stiff on cooling." *Ed.*

This is little employed. It may be used for keeping the skin soft and smooth in cold weather.

Off. Prep. Unguentum Oxidi Zinci, *Ed.;* Unguentum Oxidi Zinci Impuri, *Ed.* W.

LINIMENTUM TEREBINTHINÆ. *U.S., Lond., Dub.* *Liniment of Turpentine.*

"Take of Oil of Turpentine *half a pint;* Resin Cerate *a pound.* Add the Oil of Turpentine to the Cerate, previously melted, and mix them." *U.S., Lond., Dub.*

This is the liniment originally proposed by Dr. Kentish, and subsequently so highly lauded as a remedy in burns and scalds. It should be applied as soon after the occurrence of the accident as possible, and should be suspended when the peculiar inflammation excited by the fire is removed. The best mode of application is to cover the burned or scalded surface with pledgets of patent lint saturated with the liniment. It should not be allowed to come in contact with the sound parts. W.

* * *

MAGNESIA.

Preparations of Magnesia.

MAGNESIA. *U.S., Lond., Ed., Dub.* *Magnesia.*

"Take of Carbonate of Magnesia *any quantity.* Put it into an earthen vessel, and expose it to a red heat for two hours, or till the addition of Vinegar produces no effervescence." *U.S.*

"Take of Subcarbonate of Magnesia *four ounces.* Heat it intensely for two hours, or until Diluted Acetic Acid dropped upon it excites no effervescence." *Lond.*

"Let Carbonate of Magnesia be exposed, in a crucible, to a red heat for two hours; then let it be kept in well stopped vessels." *Ed.*

"Take of Carbonate of Magnesia *any quantity.* Put it into a crucible, and subject it to a strong heat for two hours. When the Magnesia has become cool, preserve it in a glass vessel." *Dub.*

By exposure to a red heat, the water and carbonic acid of the carbonate of magnesia are expelled, and the earth is obtained pure. According to Dr. Black, the carbonate loses seven-twelfths of its weight by calcination. Brande says that the loss varies from 50 to 60 per cent. of which from 15 to 20 per cent. is water. About the close of the process the earth exhibits a luminous or phosphorescent appearance, which is said to be a good criterion of its freedom from carbonic acid. (*Duncan.*) A more certain indication, however, is the absence of effervescence when muriatic acid is added to a little of the magnesia, previously mixed with water. It is an error to suppose that a very intense heat is requisite in the calcination. The temperature of ignition is sufficient for the expulsion of the water and carbonic acid, and any increase serves only to render the magnesia harder, denser, less readily soluble in acids, and consequently less useful as a medicine. In order to ensure a pure product, care should be taken that the carbonate employed be free from lime. It should be rubbed to powder before being introduced into the pot or crucible; and as in consequence of its levity it occupies a very large space, the plan has been proposed of moistening and compressing it in order to reduce its bulk. The magnesia may thus be obtained of greater density; but this is an equivocal recommendation; and the French pharmaceutical writers direct, that the vessels employed should be sufficiently large to contain a considerable quantity of the carbonate, without the necessity of resorting to compression. The officinal direction, to keep the magnesia, after it has been prepared, in well stopped glass vessels, is founded on the fact that it absorbs carbonic acid and water from the air; but the absorption goes on slowly, and the caution is often neglected in the shops. Its great bulk renders its introduction into small bottles inconvenient. A four ounce bottle holds only about an ounce of the purest and finest magnesia. But its specific gravity is greatly increased by trituration; and four times the quantity may thus be got into the same space. (*Journ. of the Phil. Col. of Pharm.* iii. 198.) The density of *Henry's magnesia*, which is at least four times that of the earth prepared in the ordinary way, has been ascribed to this cause. It has also been attributed to the influence of intense heat employed in the calcination; and both causes may contribute to it. The conjecture has even been advanced, that this magnesia, which has enjoyed so great a popularity in England and this country, is prepared by precipitating a solution of sulphate of magnesia by caustic potassa, as the earth afforded by this plan is comparatively dense. It is difficult to find any reasonable ground for the preference given to Henry's magnesia. If its density be owing to the employment of an intense heat in the calcination, it is rather an objection than otherwise, as its solubility in acids is thus diminished. In France the earth is esteemed in proportion to its levity. It is asserted that the magnesia, prepared from the carbonate procured by precipitating the sulphate of magnesia with carbonate of soda, is softer to the touch, and bears a closer resemblance to Henry's than that prepared from the ordinary carbonate. The fact is explained by the presence in common magnesia of a little sulphate of potassa, from which it is difficult entirely to free it in consequence of the sparing solubility of this salt, and of a portion of silica which originally existed in the carbonate of potassa employed to decompose the sulphate of magnesia, and of which the carbonate of soda is destitute.

Properties, &c. Pure magnesia is in the state of a very light, white, inodorous powder, of a feeble alkaline taste. Its sp. gr. is commonly stated at 2.3. It was deemed infusible, till melted by means of the compound blowpipe of Dr. Hare. Water sprinkled upon it is absorbed to the extent of about 18 per cent., but with scarcely any increase of temperature. It is almost insoluble, requiring, according to Dr. Fyfe, 5142 parts of water at 60°, and 36,000 parts of boiling water for solution. Water thus impregnated has no effect on vegetable colours, but magnesia itself produces a brown stain by contact with moistened turmeric paper. Magnesia is a metallic oxide, consisting of one equivalent of magnesium 12.7, and one equiv. of oxygen 8=20.7. *Magnesium* is a white, very brilliant metal, resembling silver, malleable, fusible at a low temperature, and convertible into magnesia by the combined action of air and moisture. There is a hydrate of magnesia, consisting of one equiv. of the earth and one of water.

Lime is the most common impurity in the magnesia of the shops, to which it imparts a more strongly alkaline and more disagreeable taste. It may be detected by the precipitate which it affords when oxalate of ammonia is added to a neutral solution of the magnesia in a diluted acid.

Magnesia forms with nitric and muriatic acids, salts which are soluble in alcohol and very deliquescent. It is precipitated from its saline solutions by the pure alkalies in the state of a hydrate, and by the carbonates of potassa and soda as a carbonate; but it is not precipitated by the alkaline bicarbonates nor by common carbonate of ammonia.

Medical Properties and Uses. It is antacid and laxative; and is much employed, under the name of *calcined magnesia*, in dyspepsia, sick headach, gout, and other complaints attended with sour stomach and constipation. It is also a favourite remedy in the complaints of children in which acidity of the primæ viæ is often a prominent symptom. Its antacid properties render it very useful in gravel attended with an excessive secretion of uric acid. Its advantages over carbonate of magnesia are that it may be given in a smaller dose, and does not occasion flatulence. The dose as a laxative is from thirty grains to a drachm, as an antacid merely, or antilithic, from ten to thirty grains twice a day. When it meets with no acid, it is apt to linger in the stomach or bowels, and should in this case be followed by lemonade. It should be administered in water or milk, and should be thoroughly triturated so as to render the mixture uniform. W.

MAGNESIÆ SULPHAS PURUM. *Dub.* *Pure Sulphate of Magnesia.*

"Take of Commercial Sulphuric Acid *twenty-five parts;* Water *one hundred parts;* Carbonate of Magnesia *twenty-four parts*, or as much as may be sufficient to saturate the Acid. Mix the Sulphuric Acid and Water, and then gradually add the Carbonate of Magnesia. Lastly, evaporate the filtered liquor, so that crystals may form when it cools." *Dub.*

The sulphate of magnesia prepared in the large way is sufficiently pure for medical purposes; and the above process is, therefore, superfluous. W.

◆

MELLITA.

Preparations of Honey.

Honey is used in pharmacy only as the vehicle of more active medicines. It is said to have this advantage over syrup, that its preparations are less apt to become candied; but as it contains principles which disagree with the stomachs of many persons, and as its variable consistence prevents the same exact precision in regard to proportion as is attainable with a solution of pure sugar, it is at present little employed. The preparations in which honey and vinegar are combined, are called *Oxymels*.

Medicated honeys are of a proper consistence, if, when a small quantity, allowed to cool upon a plate, is divided by the edge of a spoon, the portions do not readily coalesce. A more accurate criterion, however, is their specific gravity, which should be 1.319 (35° B.) at ordinary temperatures, and 1.261 (30° B.) at the boiling point of water. W.

MEL DESPUMATUM. *U. S., Lond., Ed., Dub. Clarified Honey.*

"Take of Honey *any quantity.* Melt it by means of a water-bath, and then remove the scum." *U.S., Lond., Ed., Dub.*

Honey by the heat of the water-bath becomes so fluid, that the wax and other lighter impurities which it contains rise to the surface, and may be skimmed off; while the heavier substances which may have been accidentally or fraudulently added, such as sand or other earth, sink to the bottom.

The following method of clarifying honey is commonly practised in France. Take of white honey 3000 parts; water 750 parts; carbonate of lime, powdered and washed, 96 parts. Mix them in a suitable vessel, and boil for three minutes, stirring constantly. Then add 96 parts of animal charcoal previously washed, heated to redness, powdered, and sifted, and boil for a few minutes. Lastly, add the whites of two eggs beat up with 500 parts of water, and bring the liquid to the boiling point. Withdraw the vessel from the fire, and after the mixture has cooled for fifteen minutes, strain it through flannel, and repeat the straining till the liquid passes perfectly clear. Should it not have the proper consistence, it should be concentrated sufficiently by a quick boiling.

The following process for clarifying common honey was proposed by M. Borde, and approved by the Society of Pharmacy at Paris. Take of common honey 5000 parts; vegetable charcoal, in powder, 320 parts; animal charcoal, in powder, 160 parts; nitric acid of 30° or 32° Baumé 40 parts; water 320 parts. Rub the two kinds of charcoal in a porcelain mortar, with the water and acid; then add the honey, and put the whole into a tinned pan. Place the vessel over the fire, and allow it to remain for eight or ten minutes without suffering it to boil; then add 1600 parts of milk in which the white of an egg has been beaten, and boil for four or five minutes. Remove the liquid from the fire, and pass it through a strainer in a warm place, repeating the straining if the first portions are not clear. Of the nitric acid employed in the process, a portion is saturated by the lime of the animal charcoal, and the remainder unites with the caseous matter of the milk, which it thus causes to coagulate: none remains in the honey. (*Dict. des Drogues.*)

Honey clarified by these processes is as clear and colourless as syrup made with sugar, but still retains a peculiar flavour. It is less disposed to ferment than crude honey, and is said not to be so liable to produce griping pain when swallowed.

Off. Prep. Confectio Rutæ, *Lond., Dub.;* Linimentum Æruginis, *Lond.;* Mel Boracis, *Lond., Ed., Dub.;* Mel Rosæ, *Lond., Ed., Dub.;* Mel Scillæ Compositum, *U.S.;* Oxymel, *Ed., Dub., Lond.;* Oxymel Colchici, *Dub.;* Oxymel Scillæ, *U.S., Lond., Dub.* W.

MEL BORACIS. *Lond., Dub.* MEL SUB-BORATIS SODÆ. *Ed. Honey af Borax.*

"Take of Subborate of Soda, in powder, *a drachm;* Clarified Honey *an ounce.* Mix them." *Lond., Dub.*

"Take of Sub-Borate of Soda, in powder, *one part;* Clarified Honey *eight parts.* Mix them." *Ed.*

This preparation might well be left to extemporaneous prescription. It is used in aphthous ulcerations of the mouth. W.

MEL ROSÆ. *Lond., Dub.* MEL ROSÆ GALLICÆ, *Ed. Honey of Roses.*

"Take of Petals of the Red Rose, dried, *four ounces;* Boiling Water *three pints;* Clarified Honey *five pounds.* Macerate the Petals in the Water for six hours, and strain; then add the Honey, and by means of a water-bath, boil the liquor down to the proper consistence." *Lond.*

The *Edinburgh College* directs *an ounce* of the red rose leaves, dried, *a pound* of boiling water, and *sixteen ounces* of clarified honey; and proceeds as above, without using the water bath. The *Dublin College* employs the same proportions with the London, but uses unclarified honey, and directs that the scum which rises during the boiling should be removed.

We prefer the process of the London College. The preparation has the flavour of the rose with its slight astringency, and forms a pleasant addition to the gargles employed in inflammation and ulceration of the mouth and throat. W.

MEL SCILLÆ COMPOSITUM. *U.S.* *Compound Honey of Squill. Hive-Syrup.*

"Take of Squill bruised, Seneka bruised, each, *four ounces;* Tartrate of Antimony and Potassa *forty eight grains;* Clarified Honey *two pounds;* Distilled Water *four pints.* Pour the Distilled Water upon the Squill and Seneka, and boil to one half; strain, and add the Clarified Honey; then boil down to three pints, in which dissolve the Tartrate of Antimony and Potassa." *U. S.*

This is the preparation commonly known by the name of *Coxe's Hive Syrup.* The degree of evaporation directed by the Pharmacopœia is insufficient, and it has been found that the resulting preparation invariably ferments. It measures only 20½° Baumé, a degree of concentration which is by no means sufficient for syrups, and still less so for the preparations of honey. If boiled down to two pints instead of three, it will have a suitable consistence, measuring 30° Baumé, and will be found to keep much better. In this case, in order to preserve the due proportion of tartar emetic, only thirty-two grains should be added.

The compound honey of squill combines the virtues of seneka, squill, and tartar emetic, of the last of which it contains one grain in every fluidounce. It is emetic, diaphoretic, expectorant, and frequently cathartic; and may be given with advantage in mild cases of croup, in the latter stages of severe cases when the object is to promote expectoration, and in other pectoral affections in which the same indication is presented. As an emetic in inflammatory croup and infantile catarrh, we decidedly prefer a simple solution of tartar emetic in water. The dose of the compound honey of squill is for children from ten drops to a fluidrachm, according to the age, and should be repeated in cases of croup every fifteen or twenty minutes till it operates. As an expectorant for adults the dose is twenty or thirty drops. W.

OXYMEL. *Ed., Dub.* OXYMEL SIMPLEX. *Lond.* *Oxymel.*

"Take of Clarified Honey *three pounds;* Diluted Acetic Acid [Distilled Vinegar] *two pints.* Boil them down in a glass vessel, with a gentle heat, to the proper consistence." *Lond.*

The *Edinburgh College* orders three parts of clarified honey, and two parts of distilled vinegar, and proceeds as above. The *Dublin College* takes two pounds of crude honey, and a pint of distilled vinegar; and boils them to the consistence of syrup, removing the scum as it rises.

This mixture of honey and vinegar forms a pleasant addition to gargles, and is sometimes used as a vehicle of expectorant medicines, and to impart flavour to drinks in febrile complaints. W.

OXYMEL COLCHICI. *Dub.* *Oxymel of Meadow Saffron.*

"Take of the fresh Bulb of Meadow Saffron, cut into thin slices, *an ounce;* Distilled Vinegar *a pint;* Clarified Honey *two pounds.* Macerate the Meadow Saffron with the Vinegar, in a glass vessel, for forty-eight hours. Strain the liquor, with strong expression, from the Bulb, and add the Honey. Lastly, boil the mixture, frequently stirring it with a spatula, to the consistence of a syrup." *Dub.*

This preparation is seldom used in this country, and could not indeed be conveniently prepared, according to the above directions, as we have not the fresh bulbs. It is in no respect superior to the wine of colchicum, by which it has been superseded. The dose is a fluidrachm, repeated twice a day, and gradually increased till it produces the desired effect. W.

OXYMEL CUPRI SUBACETATIS. *Dub.* LINIMENTUM ÆRUGINIS. *Lond.* *Oxymel of Subacetate of Copper.*

"Take of Verdigris, in powder, (Prepared Subacetate of Copper, *Dub.*) *an ounce;* Vinegar (Distilled Vinegar, *Dub.*) *seven fluidounces;* Clarified Honey *fourteen ounces.* Dissolve the Verdigris in the Vinegar, and strain the solution through linen; then gradually add the Honey, and boil down to a proper consistence." *Lond., Dub.*

This is an external stimulant and escharotic, and was formerly called *mel Ægyptiacum.* It is employed either undiluted or mixed with some mild ointment, to destroy fungous granulations, or repress their growth. In the latter state, it is a useful stimulant to flabby, indolent, and ill conditioned ulcers; and largely diluted with water has been used as a gargle in venereal ulcerations of the mouth and throat. W.

OXYMEL SCILLÆ. *U.S., Lond., Dub.* *Oxymel of Squill.*

"Take of Clarified Honey *three pounds;* Vinegar of Squill *two pints.* Boil them in a glass vessel, by means of a water-bath, to a proper consistence." *U.S.*

The *London* and *Dublin* processes differ from the above only in boiling over a gentle fire, instead of by means of a water-bath.

This preparation has the virtues of squill, but is not superior in any respect to the syrup, while it is of a less definite strength, in consequence of the want of precision in the degree of evaporation. Prepared according to the directions of the London and Dublin Colleges, it would be very liable to be injured by heat. It is chiefly used as an expectorant in chronic catarrh, humoral asthma, hooping cough, and generally in those states of the pulmonary organs in which the bronchial tubes are loaded with a viscid mucus of difficult expectoration. The dose is from one to two fluidrachms. In large doses it is emetic, and as such may sometimes be given with advantage in infantile croup and catarrh. W.

MISTURÆ.

Mixtures.

This term is applied, in the language of pharmacy, to those preparations in which insoluble substances, whether solid or liquid, are suspended in watery fluids by the intervention of gum Arabic, sugar, the yolk of eggs, or other viscid matter. When the suspended substance is of an oleaginous nature, the mixture is sometimes called an *emulsion.* The object of these preparations is usually to facilitate the administration, to conceal the taste, or to obviate the nauseating effects of unpleasant medicines; and their perfection depends upon the intimacy with which the ingredients are blended. Some skill and care are requisite to the production of a uniform and perfect mixture. As a general rule, the body to be suspended should be thoroughly mixed by trituration with the substance intended to act as the intermedium, before the watery vehicle is added. In the case of the liquid balsams and oils, if gum Arabic be employed as the intermedium, it should be previously brought to the state of mucilage of the consistence directed in the U.S. Pharmacopœia. The white of eggs is frequently ordered by physicians as the suspending substance, but it is inferior for this purpose to the yolk, or to gum Arabic. When the white is used it should be previously well beaten, and incorporated with the oleaginous or balsamic substance before the water is added.* Mixtures are generally the objects of extemporaneous prescription; but a few have been deemed of sufficient importance to merit a place in the Pharmacopœias. They should be prepared only when wanted for use. W.

MISTURA AMMONIACI. *U.S., Lond., Dub. Ammoniac Mixture.*

"Take of Ammoniac *two drachms;* Water *half a pint.* Rub the Ammoniac with the Water gradually added, until they are thoroughly mixed." *U.S., Lond.*

The *Dublin College* directs a drachm of ammoniac to be rubbed with eight fluidounces of pennyroyal water, and the mixture to be strained through linen.

In this mixture the insoluble part of the ammoniac is suspended by means of the gum, imparting a milky appearance to the preparation, which, from this circumstance, was formerly called *lac ammoniaci.* The greater portion of the resin subsides upon standing. The mixture is slightly curdled by acids. The dose is from one to two tablespoonfuls. W.

MISTURA AMYGDALÆ. *U.S.* MISTURA AMYGDALARUM. *Lond.* EMULSIO ACACIÆ ARABICÆ. *Ed.* EMULSIO ARABICA. *Dub. Almond Mixture.*

"Take of Almond Confection *an ounce;* Distilled Water *half a pint.* Rub the Confection with the Water gradually added, until they are thoroughly mixed; then strain." *U.S.*

The *London College* directs the same ingredients, but in double the quantity, and proceeds in the same manner as above.

"Take of Mucilage of Gum Arabic *two ounces;* Almonds *an ounce;* Refined Sugar *half an ounce;* Water *two pounds and a half.* Blanch the almonds by steeping them in hot water and peeling them; then beat them diligently in a stone mortar, first with the Sugar, and afterwards with the Mucilage, gradually adding the Water; lastly, strain through linen." *Ed.*

"Take of Gum Arabic, in powder, *two drachms;* Sweet Almonds, blanched, Refined Sugar, each, *half an ounce;* Water *a pint.* Dissolve the Gum in the heated Water, and when the solution is almost cold, gradually pour it upon the Almonds, previously well beaten with the Sugar, triturating at the same time so as to form an emulsion; then strain." *Dub.*

EMULSIO AMYGDALI COMMUNIS. *Ed.* MISTURA AMYGDALARUM. *Dub. Almond Emulsion.*

"Take of Sweet Almonds *an ounce;* Refined Sugar *half an ounce;* Water

---

* For some good practical observations upon the preparation of mixtures, the reader is referred to a communication published in the Journal of the Philadelphia College of Pharmacy, vol. iv. p. 11, by W. Hodgson, Jun.

two pounds and a half. Blanch the Almonds by steeping them for a short time in hot water, and peeling them; then beat them diligently with the Sugar in a stone mortar, gradually adding the Water; and strain the liquor." *Ed.*

"Take of Sweet Almonds, blanched, *an ounce and a half;* Bitter Almonds *two scruples;* Refined Sugar *half an ounce;* Water *two pints and a half.* Triturate the Almonds with the Sugar, adding the water by degrees, and strain." *Dub.*

As the almond mixture of the U.S. and London Pharmacopœias is prepared from the almond confection which contains gum Arabic, it arranges itself with the Arabic emulsion of the Edinburgh and Dublin Colleges; while the almond emulsion of the Edinburgh College, and the almond mixture of the Dublin, containing no gum Arabic, properly come together. All the preceding preparations, however, may be considered as identical in properties; for the gum Arabic is, like almonds, merely demulcent; and the proportion of bitter almonds in the mixture of the Dublin College is too small to produce any sensible effect on the system.

The oleaginous matter of the almonds is suspended, by means of their albumen and gum, in the water, forming a milky emulsion. When the almonds themselves are employed, as in the Edinburgh and Dublin processes, care should be taken to reduce them to the consistence of a paste previously to the addition of the water; and with each successive portion of fluid a uniform mixture should be formed, before another portion is added. The use of the confection, as directed in the U.S. and London Pharmacopœias, very much facilitates the process. Common water, when not very impure, may be properly substituted for the distilled. Great care should be taken to select the almonds perfectly free from rancidity. The mixture is not permanent. Upon standing, the oil rises like thick cream to the surface, and the separation is effected more quickly by heat, alcohol, and the acids, which coagulate the albumen. The preparation, in warm weather, soon becomes sour, and unfit for use.

The almond mixture has a bland taste, and may be used as a pleasant demulcent in catarrhal and dysenteric affections, and irritation or inflammation of the urinary passages. To be of any service it must be freely employed. From two to eight fluidounces may be taken at once. It is occasionally employed as the vehicle of less pleasant medicines; but should not be used in connexion with any considerable quantity of tinctures, acidulous salts, or other substances containing an excess of acid.

A preparation from almonds much employed in Europe, and sometimes in this country, is the *syrup of orgeat*, which is directed to be made in the following manner by the French Codex. "Take of sweet almonds, blanched, 500 parts; bitter almonds, blanched, 250 parts; refined sugar 875 parts. Beat them together for a long time in a marble mortar, with a wooden pestle, gradually adding 125 parts of water, so as to form a soft and homogeneous mass. Dilute the mass thus formed with 1,875 parts of water, so as to form an emulsion; then strain with expression, and to the strained liquor add 2,500 parts of refined sugar. Heat the mixture over a gentle fire, stirring constantly, till the sugar is dissolved; then strain, and to the syrup when nearly cold, add 96 parts of orange flower water, or 16 parts of the tincture of lemon-peel." This syrup is used as a demulcent and gentle anodyne in coughs and nervous irritations, and in order to flavour drinks and mixtures. It may be given in the dose of an ounce. W.

MISTURA ASSAFŒTIDÆ, *U.S.*, *Lond.* MISTURA ASSÆFŒTIDÆ. *Dub.* *Assafetida Mixture.*

"Take of Assafetida *two drachms;* Water *half a pint.* Rub the Assafetida with the Water gradually added, until they are thoroughly mixed." *U.S.*, *Lond.*

The *Dublin College* directs one drachm of assafetida and eight fluidounces of pennyroyal water.

This mixture, from its whiteness and opacity, is frequently called *lac assafœtidæ*, or milk of assafetida. It is, as a general rule, the best form for the administration of this antispasmodic, being less stimulant than the tincture, and more prompt in its action than the pill. Its excessively disagreeable smell and taste are, however, objections, which induce a frequent preference of the last mentioned preparation. It is very often employed as an enema. The dose is from one to two tablespoonfuls, frequently repeated. From two to four fluidounces may be given by the rectum. W.

MISTURA CALCIS CARBONATIS. *U.S.* MISTURA CRETÆ. *Lond.*, *Dub.* POTIO CARBONATIS CALCIS. *Ed.* *Mixture of Carbonate of Lime. Chalk Mixture.*

"Take of Prepared Carbonate of Lime [prepared chalk] *half an ounce;* Sugar [refined], Gum Arabic in powder, each, *two drachms;* Cinnamon Water, Water, each, *four fluidounces.* Rub them together till they are mixed." *U.S.*

The *London College* orders half an ounce of prepared chalk, three drachms of refined sugar, half an ounce of powdered gum Arabic, and a pint of water. The formula of the *Dublin College* is the same, except that an ounce of mucilage of gum Arabic is substituted for the half ounce of gum in powder. The *Edinburgh College* takes an ounce of prepared carbonate of lime, half an ounce of refined sugar, and two ounces of mucilage of gum Arabic; and having rubbed them together, adds gradually two pounds and a half of water, and two ounces of spirit of cinnamon.

We prefer the process of the U.S. Pharmacopœia. The mixture of the London and Dublin Colleges is without any aromatic addition; that of the Edinburgh College is in too large a quantity.

This mixture is a convenient form for administering chalk, and is much employed in looseness of the bowels accompanied with acidity. Laudanum and kino or catechu are very often added to increase its astringency. The dose is a tablespoonful frequently repeated. W.

MISTURA CAMPHORÆ CUM MAGNESIA. *Dub.* *Mixture of Camphor with Magnesia.*

"Take of Camphor *twelve grains;* Carbonate of Magnesia *half a drachm;* Water *six ounces* [fluidounces.] Triturate the Camphor with the Magnesia, adding the Water gradually, and mix." *Dub.*

This differs from the *Aqua Camphoræ* of the U.S. Pharmacopœia, in which, though the camphor is dissolved by the intervention of magnesia, the latter is afterwards separated by filtration. In the above mixture the carbonate of magnesia is retained; and an anodyne, antacid, and laxative draught is formed, which, though it may sometimes be given with advantage, hardly deserves a place among the officinal preparations. W.

MISTURA CORNU USTI. *Lond.* *Mixture of Burnt Hartshorn.*

"Take of Burnt Hartshorn *two ounces;* Gum Arabic *an ounce;* Water *three pints.* Boil down to two pints, constantly stirring, and strain. *Lond.*

This formula is altogether absurd. The phosphate of lime, which constitutes almost the whole of the burnt hartshorn, is insoluble in water hot or cold, and might be suspended by means of gum Arabic without boiling. It is, moreover, quite inert as a medicine. W.

MISTURA FERRI AROMATICA. *Dub.* *Aromatic Mixture of Iron.*

"Take of Crown Bark, in coarse powder, *an ounce;* Columbo Root, sliced, *three drachms;* Cloves, bruised, *two drachms;* Iron Filings *half an ounce.* Digest for three days in a close vessel, with occasional agitation, with such a quantity of Peppermint Water as will yield a mixture of twelve ounces after filtration; then add, of Compound Tincture of Cardamom *three ounces;* Tincture of Orange Peel *three drachms.*" *Dub.*

This is an aromatic infusion of Peruvian bark and columbo, and has not the slightest claim to the title given it in the Pharmacopœia, as it contains but a very small proportion of iron, and that in a state of solution, not of mixture. In consequence of the action of some of the vegetable principles upon the filings, enough of the metal is taken up to impart a greenish-black colour to the liquor; but the quantity is not appreciable, as the filings seem to be scarcely diminished by the process. The preparation may be given as a tonic in the dose of one or two fluidounces. W.

MISTURA FERRI COMPOSITA. *U.S., Lond., Dub.* *Compound Mixture of Iron.*

"Take of Myrrh, in powder, *a drachm;* Carbonate of Potassa, *twenty-five grains;* Rose Water *half a pint;* Sulphate of Iron, in powder, *a scruple;* Spirit of Lavender *half a fluidounce;* Sugar [refined] *a drachm* Rub together the Myrrh, Carbonate of Potassa, and Sugar, and during the trituration, add gradually, first the Rose Water and Spirit of Lavender, and lastly the Sulphate of Iron. Pour the mixture immediately into a glass bottle, which is to be well stopped." *U.S.*

"Take of Myrrh, in powder, *a drachm;* Subcarbonate of Potassa [Carbonate of Potassa] *twenty-five grains;* Rose Water *seven fluidounces and a half;* Sulphate of Iron, in powder, *a scruple;* Spirit of Nutmeg *half a fluidounce;* Refined Sugar *a drachm.* Rub the Myrrh with the Spirit of Nutmeg and Subcarbonate of Potassa; and to these, while rubbing, add first the Rose Water with the Sugar, and then the Sulphate of Iron. Put the mixture immediately into a suitable glass vessel, and stop it." *Lond., Dub.*

This is very nearly the same with the celebrated tonic or antihectic myrrh mixture of Dr. Griffith. The sulphate of iron is decomposed by the carbonate of potassa, with the production of sulphate of potassa and protocarbonate of iron; while the excess of the alkaline carbonate forms a saponaceous compound with the myrrh. The mixture is at first of a greenish colour, which it loses upon exposure to the air, in consequence of the conversion of the protoxide of Iron of the protocarbonate into the red or peroxide. It may, however, be kept for some time without change, if the vessel in which it is contained be well closed; but the best plan is to prepare it only when it is wanted for use. The finest pieces of myrrh in lump should be selected, and rubbed down for the occasion with a little of the rose water, as the powdered myrrh of the shops is often impure, and does not make a good mixture.

It is a good tonic in debility of the digestive organs, especially when attended with derangement of the menstrual function. Hence it is used with advantage in chlorosis and hysterical affections. It is also much employed in the hectic fever of phthisis and chronic catarrh. It is contra-indicated by the existence of inflammation of the gastric mucous membrane. The dose is one or two fluidounces two or three times a day. W.

MISTURA GUAIACI. *Lond.* *Mixture of Guaiac.*

"Take of Guaiacum Gum-resin *a drachm and a half;* Refined Sugar *two drachms;* Mucilage of Gum Arabic *two fluidrachms;* Cinnamon Water *eight fluidounces.* Rub the Guaiac with the Sugar, then with the mucilage, and to these, while rubbing, add gradually the Cinnamon Water." *Lond.*

From one to three tablespoonfuls of this mixture may be given for a dose, and repeated two or three times a day, or more frequently. W.

MISTURA MOSCHI. *Lond.* *Musk Mixture.*

"Take of Musk, Gum Arabic, in powder, Refined Sugar, each, a *drachm;* Rose Water *six fluidounces.* Rub the Musk with the Sugar, then with the Gum, adding gradually the Rose Water." *Lond.*

The musk should be thoroughly rubbed with the gum and sugar before the addition of the water. The mixture will be more permanent if made with twice the quantity of gum directed. The dose is a fluidounce. W.

MORPHIA.

Preparations of Morphia.

MORPHIA. *U.S.* *Morphia.*

"Take of Opium, sliced, *a pound;* Distilled Water *six pints;* Alcohol *a gallon;* Water of Ammonia *six fluidounces.* Macerate the Opium with four pints of the Distilled Water, in a glass vessel, for six days, frequently stirring; then filter through paper. Wash the residue with the remainder of the Water, and filter as before. Mix the filtered liquors, and add first five pints of the Alcohol, and afterwards three fluidounces of the Water of Ammonia, previously mixed with half a pint of the Alcohol. After twenty-four hours, pour in the rest of the Water of Ammonia, mixed, as before, with half a pint of the Alcohol, and set the liquor aside for a day, that crystals may form. To purify these, boil them with the remainder of the Alcohol till they are dissolved, filter the solution while hot, and set it aside to crystallize." *U.S.*

The process for procuring morphia will be better understood by a previous acquaintance with the properties and chemical relations of this principle.

Morphia crystallizes in the form of small, colourless, shining crystals, which appear to be rectangular prisms, and contain 6.33 per cent. of water. It is inodorous and bitter. Exposed to a moderate heat it loses the crystalline form, becoming white and opaque. At a higher temperature it melts, forming a yellowish liquid, which becomes white and crystalline upon cooling. Heated in the open air it burns with a bright flame. It is insoluble in cold water, soluble in rather less than 100 parts of water at 212°, slightly soluble in cold alcohol, and freely so in boiling alcohol, which precipitates it upon cooling. It is dissolved also by the fixed and volatile oils, but very slightly if at all by ether. Its solution restores the blue colour of litmus paper reddened by acids, and turns the yellow of turmeric to brown. With the acids it forms salts, which are generally soluble; and are decomposed by the alkalies. The solutions of potassa and soda are also capable of dissolving morphia, which is precipitated slowly on exposure to the air, in consequence of the absorption of carbonic acid. Aqua ammoniæ has to a certain extent the same solvent power; and hence the necessity, in precipitating morphia by this alkali, not to employ it in great excess. Morphia and its salts, by the contact of nitric acid, assume a blood-red colour, which ultimately changes to yellow. When added to a solution of iodic acid, or an acidulous iodate, they redden the liquid and set iodine free. (*Serullas.*) According to Robinet, they assume a fine blue colour with the salts of the peroxide of iron, especially the permuriate. Morphia is precipitated from its solutions, according to Dublanc, by the infusion of galls, but not by pure gallic acid. (*Journ. de Pharm.* xvi. 429.) Wittstock, on the contrary, states that the salts of morphia are not disturbed by the infusion of galls when entirely pure; but yield a precipitate if contaminated with the smallest proportion of narcotin. (*Berzelius, Traité de Chimie*, v. 132.) The ultimate constituents of morphia, are oxygen, hydrogen, carbon, and nitrogen. Liebig gives 10.33 and 75.38 as the mutually saturating quantities of sulphuric acid and anhydrous morphia; which makes the equivalent of this alkali 292.6.

Various processes for preparing morphia have been proposed. In most of them the morphia is extracted from the opium either in the state of meconate, or in combination with some acid added to the menstruum; is precipitated from its solution by ammonia or magnesia; and is then purified by the agency of alcohol, or by repeated solution in a dilute acid and precipitation. The processes may be considered under three heads; 1st, those in which ammonia is employed as the precipitant, and alcohol as the agent of purification; 2d, those in which magnesia is used instead of ammonia; and 3d, those in which the alkali is obtained pure without the agency of alcohol.

1. Sertürner made an infusion of opium in distilled water, precipitated the morphia by ammonia in excess, dissolved the precipitate in dilute sulphuric acid, precipitated anew by ammonia, and purified by solution in boiling alcohol and crystallization.

The process of M. Hottot, considerably followed in France, is a modification of that of Sertürner. It is as follows: "Take of commercial opium 1000 parts; macerate it in sufficient cold water to exhaust it; unite the infusions; evaporate till the liquor is at 2° Baumé; pour into it when half cooled sufficient ammonia to render the liquid neutral or slightly alkaline, about 8 parts [10 parts of the aqua ammoniæ of the U.S. Pharmacopœia]; allow the fatty matter to subside; decant, and add anew 64 parts of liquid ammonia [about 85 parts of the aq. am. of the U.S. Pharm.]; set aside the liquor for 12 hours; throw the precipitate which forms upon a filter; wash it with cold water; then treat it with 3000 parts of alcohol of 34° Baumé, and 64 parts of animal charcoal; heat the mixture in a water-bath, and filter it while boiling hot. When the liquor cools the morphia will be precipitated in crystals." (*Journ. de Pharm.* x. 479.) The alcohol may be purified by distillation, and an additional quantity of morphia may thus be obtained. In this process, the object of the first addition of ammonia is to separate the fatty matter, which might otherwise embarrass the subsequent steps of the operation. The necessity for a second solution in alcohol, or a solution in diluted sulphuric acid and precipitation, is thus avoided; but it has been asserted that considerable morphia is associated with the fatty matter, and that loss is thereby incurred.

The process of the U.S. Pharmacopœia is an improvement upon the above, and is essentially the same with that of Dr. Edward Staples, published in the Journal of the Philadelphia College of Pharmacy, Vol. 1. p. 15. Without repeating a description of the process, we shall make such remarks upon its several steps, as appear to us likely to be of practical advantage. The employment of water as the solvent is justified by the almost universal practice. It is true, that Sertürner sometimes employed dilute acetic acid, and Vogel states that the product thus obtained is much greater than when water alone is used. Dr. Staples, also, recommends diluted vegetable acids in the treatment of opium of medium quality. But when the opium is properly comminuted, either by being reduced to a coarse powder when dry, or by being finely sliced, in its ordinary state, water alone will be found sufficiently to extract the morphia, by a protracted digestion, such as that directed in the Pharmacopœia. The acids have this disadvantage, that they dissolve more of the narcotina than pure water, and thus render the ultimate product more impure; for the narcotina which is originally taken up continues associated with the morphia in all the subsequent steps of the process. It has been proposed to expose the opium to fermentation with water and yeast, in order to facilitate the extraction of the morphia. By this plan M. Blondeau succeeded in procuring more of the alkaline principle than he could obtain by the ordinary mode; and his results were confirmed by the experiments of MM. Robiquet and Guibourt. According to these latter chemists, no alcohol is produced during the fermentation, which appears to act merely by disengaging morphia from the combinations in which it naturally exists, and which tend to counteract the solvent power of the menstruum. Alcohol has been proposed as the solvent by M. Guillermond, but it is liable to the objection that it dissolves also the resin, a portion of which is afterwards precipitated with the morphia and embarrasses the process. Much of the resin, however, may be separated by distilling most of the alcohol from the tincture, and then adding water. The resin is precipitated, and the liquor may now be treated in the same manner as the aqueous infusion. On the whole, the officinal mode of extraction will probably be found most satisfactory; and should the opium not be exhausted, maceration in successive portions of water may be resorted to and the mixed liquors reduced by evaporation to the quantity ordered in the Pharmacopœia. The solution of opium having been prepared, the next object is to decompose the meconate or other salt of morphia, according as water alone, or a diluted acid has been employed as the menstruum. For this purpose water of ammonia is added, which seizes the acid and precipitates the vegetable alkali; but much colouring matter will be thrown down along with the latter, occasioning some trouble to separate it, unless measures are taken to obviate this effect. The object is gained by mixing the infusion with alcohol, previously to the addition of the ammonia, and by employing the water of ammonia itself in connexion with alcohol, as directed in the Pharmacopœia. This is the peculiarity and chief merit of the process of Dr. Staples. By the presence of the alcohol in all parts of the liquor, the colouring matter is dissolved as soon as it is separated by the ammonia, and the morphia is thus precipitated in a much purer state. The advantage of adding the ammonia in separate portions is, that the morphia being thus more slowly disengaged, can be more completely deprived of its impurities by the alcohol of the mixure, than if the whole were liberated at once. It is necessary to be careful that the ammonia be not in great excess, as it has the property, under these circumstances, of dissolving the morphia in some degree, and will therefore lessen the product, while waste is incurred by its own unnecessary consumption. The quantity of water of ammonia ordered by the Pharmacopœia is too great, if it be used of the proper officinal strength (sp. gr. 0.944). Very little more should be added than is sufficient to saturate the acid present. Four fluidounces will be found abundantly sufficient for this purpose. But the water of ammonia of the shops is often much below the officinal standard, and this should always be attended to in the process. Alcohol is mixed with the ammonia before it is added, in order that every particle of the separated morphia may come in contact with the particles of this fluid, and thus have the opportunity of being deprived of colouring matter. The crystals of morphia obtained by this first operation have a light yellowish colour, and are much purer than when no alcohol is added to the infusion before the precipitation by ammonia. According to Dr. Staples, opium yields from 10 to 12½ per cent. of these crystals. Their purification by solution in boiling alcohol, is the concluding step of the operation. The liquid, on cooling, deposites the morphia in a crystalline state and nearly free from colour. As cold alcohol retains a portion of the morphia in solution, it should not be employed in too large a quantity. Alcohol somewhat reduced by water, is preferable to the highly rectified spirit; as it is less capable of holding the morphia in solution when cold. It is sufficiently strong for the purpose at 25° Baumé (sp. gr. 0.9032). The impure morphia remaining in the alcohol may be obtained by distilling off the latter, and when sufficiently accumulated, may be purified by a separate operation. The crystals of morphia may also be purified by solution in dilute sulphuric acid, digestion with animal charcoal deprived of earthy matter, filtration, and precipitation by ammonia. If alcohol be added to the solution previously to the ammonia, the digestion with animal charcoal may be dispensed with, as the alcohol retains the colouring matter.

2. The process in which magnesia is employed instead of ammonia to precipitate the morphia is that of Robiquet. It is as follows. Select the dryest opium, divide it into small pieces, and macerate it with cold water for six days; then separate the infusion, and knead the residuary mass with a fresh portion of water, in order that all the soluble parts may be extracted. Unite the liquors; add magnesia in the proportion of 5 parts to 100 of the opium used, and boil for fifteen minutes. The magnesia decomposes the meconate of morphia, uniting with the acid, and separating the morphia, which is precipitated with the excess of the earth, an insoluble submeconate of magnesia, and colouring matter. Collect the precipitate upon a filter, and having washed it with water, allow it to drain and dry; then remove it from the filter, reduce it to powder, and digest it with a gentle heat in alcohol of 22° Baumé (sp. gr. 0.9212). Decant the solution, and repeat the digestion in fresh portions of alcohol till this liquid ceases to extract any thing from the precipitate. Most of the colouring matter is thus removed. Place the residue upon a filter and allow it to drain; then remove it, treat it with strong boiling alcohol, and filter the alcoholic solution while boiling hot. Upon cooling, the solution deposites the morphia. Treat the impure residuary mass several times in the same manner with fresh portions of alcohol. After the deposition of the morphia, the mother liquors may be made to furnish a fresh supply by evaporation at a low temperature. If the morphia, thus procured, be not colourless, it may be rendered so by boiling in alcohol with a small portion of pure animal charcoal, filtering the liquid while hot, and allowing it to crystallize.

The process of Robiquet occupies a longer time, requires the consumption of a larger proportion of alcohol, and is attended with a greater loss of morphia, in consequence of the frequent washings, than the processes in which ammonia is employed as the precipitant. Some one of the latter, therefore, is generally preferred.

3. A process for extracting morphia without the employment of alcohol was devised by MM. Henry Jun. and Plisson, but is too tedious for practical use. The process of Drs. Gregory and Robertson of Edinburgh, by which the muriate of morphia is first procured, is more convenient, and has been adopted, to a considerable extent, in Europe. The following account of it is from the last edition of Turner's Chemistry. "The aqueous solution of opium is concentrated in a vessel of tinned iron, or other evaporator, to the consistence of a thin syrup, when a slight excess of chloride of calcium, neutral and quite free from iron, is added; the mixture is boiled for a few minutes, and then poured into an evaporating basin. When cold, the

hydrochlorates [muriates] are taken up in water, which is added until a copious separation of resinous flocks ensues, leaving the insoluble meconate and sulphate of lime with a good deal of colouring matter. The clear liquid is again evaporated to a syrupy consistence, a little marble being added to ensure perfect neutrality, the warm fluid is poured off the sediment into a clean capsule, and is well stirred during crystallization. The mass is then put into a stout cloth, and the liquid part, containing chloride of calcium [muriate of lime], the hydrochlorate [muriate] of narcotina, and colouring matter, is pressed out from the crystallized hydrochlorate [muriate] of morphia: this impure salt is redissolved in water at 70°, filtered through cloth, mixed with a little fresh chloride of calcium, crystallized, and compressed as before. It is taken up in hot water, digested for about 24 hours with animal charcoal, filtered, evaporated, crystallized, and squeezed in cloth as on former occasions; but in this part of the process a little free hydrochloric [muriatic] acid may be added with advantage, as it holds in solution any remaining colouring matter, and renders the crystallization of the hydrochlorate [muriate] of morphia more perfect. The pure salt is then dried at a temperature of 150°, and amounts on the average to 10 per cent. of the opium used, corresponding to 9.43 per cent. of crystallized morphia." The muriate of morphia thus obtained is much used in Scotland as a substitute for opium. It has, however, been proved by Robiquet to contain a portion of muriate of codeia, though, perhaps, not in sufficient quantity to interfere materially with its operation. This impurity may be separated by precipitating morphia from a solution of the muriate by means of ammonia, the codeia being left in solution. Morphia procured by this process is more free from narcotina, than that which results from either of the others described.

Various other processes, or modifications of those above described, have been proposed; but none which, in our opinion, combines the advantages of economy of time and richness of product equally with that of Dr. Staples.

Morphia, obtained in the ordinary manner, contains a considerable proportion of narcotina. It is highly probable that this ingredient exercises no influence, either beneficial or injurious, upon the operation of the morphia; but as the contrary has been supposed, various methods have been employed for separating it. The simplest and easiest is to submit the mixture to the action of sulphuric ether, which dissolves the narcotina and leaves the morphia. The agency of dilute acids, particularly the muriatic, may also be resorted to. As morphia is more soluble in this acid than narcotina, it will be exclusively dissolved, provided the acid be very much diluted, and added in quantities barely sufficient to saturate this base. The morphia may then be obtained by the addition of water of ammonia to the solution. Another mode is to dissolve the mixed bases in strong acetic acid, (of 7° Baumé or sp. gr. 1.0511, for example,) and expose the solution to heat. The narcotina is precipitated, and the morphia remaining in solution may be precipitated by diluting the liquid and adding ammonia. (See *Journ. de Pharm.* xvii. p. 640.) Wittstock advises one of the following methods. Dissolve the impure morphia in dilute muriatic acid, evaporate to the point of crystallization, and strongly express the crystals, which consist solely of the muriate of morphia, the narcotina being retained in the mother waters:—or, saturate the muriatic solution with common salt, which will render the liquor milky, and cause the narcotina to separate after some days; then precipitate the morphia by ammonia:—or, pour into the diluted muriatic solution a weak ley of caustic potassa, which, if in slight excess, will dissolve the morphia at the moment of its separation, while the narcotina is precipitated; then immediately filter the liquor, and separate the morphia by neutralizing the alkali. If the potassa be in considerable excess, a small portion of the narcotina is redissolved. (*Berzelius, Traité de Chimie.*)

The quantity of pure morphia which Turkey opium is capable of affording, varies from nine per cent. or less, to fourteen per cent., according to the quality of the drug; but much less is often obtained, in consequence of the incomplete exhaustion of the opium, or the loss in the process for preparing it.

Medical Properties. There can be no doubt that morphia is the chief, if not the exclusive narcotic principle of opium, from which, however, it differs somewhat in its mode of action. Whether the difference arises from the peculiar state of combination in which morphia exists in opium, or from other narcotic principles being associated with it, has not been determined; but the former would seem to be the probable cause, from the circumstance, that long before the discovery of this alkali, preparations of opium were habitually used, in which the properties of the medicine were somewhat similarly modified by the agency of vinegar, lemon-juice or, other vegetable acid. In consequence of its insolubility in water, morphia in its pure state is less certain in its effects than some of its saline compounds; as the mode and degree of its action must, in some measure, depend on the presence or absence of acid in the stomach, and perhaps on the peculiar character of the acid. Its salts are therefore always preferred. The acetate, sulphate, and muriate, have been employed. Between these there is a great similarity of action, and what may be said of one, in regard to its therapeutical effects, will equally apply to the others. They have the anodyne, soporific, and diaphoretic properties of opium; but are less stimulant, less disposed to constipate the bowels, and less apt to leave behind them headach, nausea, or other unpleasant effect. They are usually also more acceptable to the irritated stomach, and will often be retained, when opium or its tincture would be rejected. They are applicable to all cases where the object is to relieve pain, quiet restlessness, promote sleep, or allay nervous irritation in any shape; but are less efficient than opium in the suppression of morbid discharges, and as stimulants in low forms of disease. We have found them especially useful in the mania arising from intemperance. A great advantage which they possess, is the convenience of their external application to blistered surfaces, and the certainty of their effects when thus applied. In cases which do not admit of the internal use of opium or its preparations, the acetate or sulphate of morphia, sprinkled, in triple the ordinary dose, upon a blistered surface denuded of the cuticle, will be found to exercise upon the system all the influence it is capable of exerting when taken into the stomach. Applied in this manner, these salts are peculiarly useful in relieving violent neuralgic pains, and controlling obstinate sickness of the stomach. When intended to act on the system through the medium of the skin, they should be applied preferably to the epigastrium; when to act locally, as near the affected part as possible. When given in doses nearly, but not quite sufficient to produce sleep, they sometimes give rise to a very troublesome condition of the brain, amounting almost to delirium; but this always subsides spontaneously, or vanishes immediately upon the increase of the dose.

In over-doses, morphia and its salts produce the symptoms of narcotic poisons, though not perhaps in the same degree with a quantity of opium, equivalent in anodyne effect. The toxicological treatment is precisely the same as in the case of laudanum. (See *Opium.*)

As the proportion of acid necessary to neutralize morphia is very small, the dose of the alkali is the same as that of its salts. One-sixth of a grain may be considered equivalent to a grain of opium of the medium strength.

The acetate and sulphate of morphia are officinal; and processes are given for their preparation, under distinct heads. The *muriate* may be prepared by saturating dilute muriatic acid with morphia, evaporating, crystallizing, and pressing the crystals in bibulous paper to separate the narcotina which remains in the mother liquor. It may also be prepared directly from opium by the process of Drs. Gregory and Robertson already described. (See page 909.)

Off. Prep. Morphiæ Acetas, *U.S.;* Morphiæ Sulphas, *U.S.* W.

MORPHIÆ ACETAS. *U.S.* *Acetate of Morphia.*

"Take of Morphia, in powder, *an ounce;* Distilled Water *half a pint;* Acetic Acid *a sufficient quantity.* Mix the Morphia with the Water; then carefully drop in the Acid, constantly stirring, until the Morphia is saturated and dissolved. Evaporate the solution by means of a water-bath, to the consistence of syrup; lastly, dry the Acetate of Morphia with a gentle heat, and rub it into powder." *U.S.*

Acetic acid is employed in the process in preference to vinegar, because it can leave no impurity in the resulting salt. The solution of the morphia in the water is an indication that it is saturated. A small excess of acid is attended with no inconvenience, as it is subsequently driven off by the heat. Care is requisite not to employ too great a heat in the evaporation, as the acetate is readily decomposed, a portion of the acetic acid escaping, and leaving an equivalent portion of uncombined morphia. With attention to arrest the evaporation at a certain point, the acetate may be obtained in the state of crystals; but the crystallization is attended with some difficulty, and evaporation to dryness is almost universally preferred. Some recommend to dissolve the morphia in boiling alcohol, instead of suspending it in water, previously to the addition of the acetic acid. A less heat is thus required in the evaporation, and impurities in the morphia may often be detected, as they are apt to be insoluble in alcohol. To ascertain, in this case, whether the morphia is saturated, it is necessary to employ litmus paper, the blue colour of which should not be restored, if previously reddened by an acid. If the morphia used in preparing the acetate contain narcotina, it will be best to employ as the solvent distilled vinegar, or diluted acetic acid of the same strength, and to favour its solvent power by the application of heat. Under these circumstances it dissolves only the morphia, leaving the narcotina nearly or quite untouched. (See notice by *William Hodgson Jun.*, in the *Journ. of the Phil. Col. of Pharm.* vol. v. p. 35.)

Acetate of morphia crystallizes in the form of slender needles united in fasciculi. It is readily dissolved by water, and less easily by alcohol. As ordinarily obtained, however, by evaporation to dryness, it is not entirely soluble in water, a portion of it being uncombined morphia. To render it soluble, all that is necessary is to add a little distilled vinegar.

From an eighth to a quarter of a grain may be given for a dose, and repeated, if necessary, in order to obtain the anodyne and soporific effect of the medicine. One-sixth of a grain is about equivaleut to a grain of opium. It may be given in pill or solution. It is frequently employed externally, sprinkled on blistered surfaces, to obtain its effects upon the system. W.

MORPHIÆ SULPHAS. *U.S.* *Sulphate of Morphia.*

"Take of Morphia, in powder, *an ounce;* Distilled Water *half a pint;* Diluted Sulphuric Acid *a sufficient quantity.* Mix the Morphia with the Water; then carefully drop in the acid, constantly stirring, till the Morphia is saturated and dissolved. Evaporate the solution, by means of a water-bath, so that crystals may form when it cools. Dry the crystals upon bibulous paper." *U.S.*

In this process, the morphia is known to be saturated when it is wholly dissolved by the water. To ascertain whether the acid is added in excess, litmus paper may be resorted to. If the morphia employed contain narcotina, this will remain in the mother liquor, and will not contaminate the product. The mother liquor remaining after the first crystallization may be evaporated, so as to obtain a fresh supply of the sulphate; but if the morphia was not originally quite pure, the second product will contain the impurities, and should not be used till it has undergone further preparation. When impure morphia is employed, the mother liquor should be mixed with alcohol, or boiled with washed animal charcoal and filtered, and then decomposed by ammonia, which will precipitate the morphia. This may then be converted into sulphate in the manner directed by the Pharmacopœia.

Another mode of obtaining sulphate of morphia, is to dissolve the alkali in boiling alcohol of 36° Baumé (sp. gr. 0.8428), saturate it while hot with sulphuric acid, add animal charcoal previously washed with muriatic acid, boil for a few minutes, and filter the solution while at a boiling temperature. Upon cooling, it deposites most of the sulphate; and the remainder may be obtained by evaporating the mother liquor.

The sulphate of morphia crystallizes in beautifully white, minute, feathery crystals, which are soluble in twice their weight of boiling water. They contain, according to Liebig, in 100 parts, 14.29 of water, 10.33 of sulphuric acid, and 75.38 of morphia. By exposure to a heat of 248° F. they lose 9.66 parts of the water, but cannot be deprived of the remainder without decomposition.

The dose of the sulphate of morphia is from an eighth to a quarter of a grain, which may be given in pill or solution.

Off. Prep. Liquor Morphiæ Sulphatis. W.

LIQUOR MORPHIÆ SULPHATIS. *U.S. Solution of Sulphate of Morphia.*

"Take of Sulphate of Morphia *eight grains;* Distilled Water *half a pint.* Dissolve the Sulphate of Morphia in the Distilled Water." *U. S.*

The sulphate of morphia as found in the shops, particularly that imported from France, is not always entirely soluble in water. This sometimes, perhaps, arises from adulterations; but more frequently, in all probability, from the mode in which the sulphate is prepared. In the process of the French Codex for the preparation of this salt, the quantity of water directed for the suspension of the morphia is insufficient to hold the sulphate when it is formed in solution; and the consequence is, that upon the addition of sulphuric acid, the crystallization of the sulphate takes place before the whole of the morphia has been saturated by the acid. With the resulting salt, therefore, a portion of uncombined morphia is necessarily mixed; and this is probably the cause of the incomplete solubility of the sulphate of morphia alluded to. This explanation is rendered still more probable by the fact, that the addition of a little sulphuric acid usually remedies the defect and renders the whole soluble. Pure sulphate of morphia is readily and entirely soluble in cold water.

This solution is very convenient, by enabling the physician to prescribe a minute dose, which, in consequence of the great energy of the preparations of morphia, is very often necessary. It has the advantage that it may be kept for a very considerable length of time unchanged. The full dose for an adult is from one to two fluidrachms, containing from an eighth to a quarter of a grain of the sulphate. W.

MUCILAGINES.

Mucilages.

Mucilage, in the ordinary acceptation of the term, and in the sense in which it is employed in the U.S. Pharmacopœia, is an aqueous solution of gum or of substances closely allied to it. As used by the British Colleges it appears to signify any bland, viscid, aqueous, vegetable solution, resembling that of gum in sensible properties. W.

MUCILAGO ACACIÆ *U.S., Lond.* MUCILAGO ACACIÆ ARABICÆ. *Ed.* MUCILAGO GUMMI ARABICI. *Dub.* *Mucilage of Gum Arabic.*

"Take of Gum Arabic, in powder, *four ounces;* Boiling Water *half a pint.* Add the Water gradually to the Gum, rubbing them together, till the mucilage is produced." *U. S., Lond.*

The *Edinburgh College* directs one part of gum Arabic, in powder, to two parts of boiling water; the *Dublin College,* four ounces of the former, in coarse powder, to four fluidounces of the latter; both Colleges order the ingredients to be digested, with frequent agitation, till the gum is dissolved, and the resulting mucilage to be strained through linen.

Straining through linen is necessary to separate the foreign substances which are often mixed with gum Arabic. This mucilage is semitransparent, almost colourless if prepared from good gum, viscid, tenacious, of a feeble, peculiar odour, and nearly tasteless. If the solution of gum should be coloured, it may be rendered colourless by the addition of a concentrated solution of chlorine; and, by boiling for about half an hour so as to drive off the chlorine and muriatic acid, it may be rendered fit for use. (*Guérin.*) By keeping, mucilage becomes sour in consequence of the spontaneous generation of acetic acid; and this happens even though it be enclosed in well stopped bottles. But, according to M. Guérin, the aqueous solution of pure gum undergoes no change in vacuo. Mucilage is employed chiefly in the formation of pills, and for the suspension or diffusion of insoluble substances in water.

Off. Prep. Mistura Cretæ, *Dub.;* Mistura Guaiaci, *Lond.;* Potio Carbonatis Calcis, *Ed.* W.

MUCILAGO AMYLI. *Lond., Ed., Dub.* *Mucilage of Starch.*

"Take of Starch *three drachms* [six drachms, *Dub.*]; Water *a pint* [a pound, *Ed.*]. Rub the Starch with the Water gradually added; then boil till a mucilage is produced." *Lond., Ed., Dub.*

This Mucilage has an opaline appearance, and gelatinous consistence, and is much used as a vehicle for laudanum and other active remedies given in the form of enema. In consequence of its demulcent properties, it may be usefully employed as an enema in irritation and inflammation of the mucous coat of the rectum and large intestines. Its unpleasant flavour, when it is prepared from ordinary starch, precludes its employment by the mouth. W.

MUCILAGO GUMMI TRAGACANTHÆ. *Dub.* MUCILAGO ASTRAGALI TRAGACANTHÆ. *Ed.* *Mucilage of Tragacanth.*

"Take of Tragacanth, in powder, *two drachms;* Water *eight fluidounces.* Macerate in a covered vessel till the gum is dissolved; then strain the mucilage through linen." *Dub.*

"Take of Tragacanth, in powder, *two drachms;* Boiling Water *eight* *ounces*. Macerate for twenty-four hours, then triturate the Gum carefully that it may be dissolved, and strain the mucilage through linen." *Ed.*

A part only of tragacanth is soluble in water. The remainder swells up and forms a soft tenacious mass, which may be mechanically mixed with water, but does not form a proper solution. Hence the trituration directed by the Edinburgh College is necessary to complete the incorporation of the ingredients. The mucilage is thick and very viscid, but not permanent, as the water separates from the insoluble portion of the tragacanth on standing. It is chiefly used in making pills and troches. In consequence of its great tenacity, it may be advantageously employed for the suspension of heavy insoluble substances, such as the metallic oxides, in water. W.

OLEA DESTILLATA.

Distilled Oils.

For an account of the general properties of the volatile, essential, or distilled oils, the reader is referred to the head of *Olea Volatilia* in the first part of this work. The following are the different officinal directions for preparing them.

OLEA DESTILLATA. *U. S.*

"Put the substance from which the Oil is to be extracted into a retort or other vessel suitable for distillation, and add enough Water to cover it; then distil into a large refrigeratory. Separate the Distilled Oil from the Water which comes over with it.

"In this manner prepare OIL OF ANISE, from Anise; OIL OF CARAWAY, from Caraway; OIL OF WORMSEED, from Wormseed; OIL OF FENNEL, from Fennel-seed; OIL OF PARTRIDGE-BERRY, from Partridge-berry [leaves]; OIL OF PENNYROYAL [Oleum Hedeomæ], from Pennyroyal; OIL OF JUNIPER, from Juniper [berries]; OIL OF LAVENDER, from Lavender [flowers]; OIL OF PEPPERMINT, from Peppermint; OIL OF SPEARMINT, from Spearmint; OIL OF HORSEMINT, from Horsemint; OIL OF ORIGANUM, from Origanum [Marjoram]; OIL OF PIMENTO, from Pimento; OIL OF ROSEMARY, from Rosemary [tops]; OIL OF SASSAFRAS, from Bark of Sassafras Root." *U. S.*

OLEA DESTILLATA. *Lond.*

"OIL of ANISE, of CHAMOMILE, of CARAWAY, of JUNIPER, of LAVENDER, of PEPPERMINT, of SPEARMINT, of ORIGANUM, of PIMENTO, of PENNYROYAL [Pulegium], of ROSEMARY.

"The seeds of Anise and Caraway, the flowers of Chamomile and Lavender, the berries of Juniper and Pimento, the tops of Rosemary, and the fresh herb of the other plants are to be employed. Put any of these into an alembic, and add sufficient Water to cover it; then distil the Oil into a large refrigeratory. Let the Water which distils over with the Oils of Caraway, Peppermint, Spearmint, Pimento, and Pennyroyal be kept for use." *Lond.*

OLEA VOLATILIA. *Ed.*

"Only so much Water is to be added to the substance as will be sufficient to prevent it from being burnt when distilled. The distillation is to be commenced after due maceration, and the Oil is, lastly, to be separated from the water.

"In this manner are prepared the VOLATILE OIL of CHAMOMILE, from the flowers; of JUNIPER, from the bruised berries; of SAVINE, from the leaves; of LAVENDER, from the flowers; of SASSAFRAS, from the bruised root; of PEPPERMINT, from the herb; of PIMENTO, from the bruised fruit; of ORIGANUM, from the herb; of ANISE, from the seeds; of ROSEMARY, from the tops." *Ed.*

OLEA ESSENTIALIA. *Dub.*

"OIL of ANISEED, of CARAWAY, of FENNEL, from the seeds dried with a medium heat; of SASSAFRAS, from the bark and wood; of JUNIPER, of PIMENTO, from the berries; of LAVENDER, from the flowers; of PEPPERMINT, of SPEARMINT, of ORIGANUM, of PENNYROYAL, of ROSEMARY, of RUE, from the leaves and flowers of the plant while in flower; of SAVINE, from the leaves.

"Put the substance, previously macerated in Water, into an alembic; then by means of the vapour of boiling water, distil into a receiver. Separate by a proper apparatus, the Oil which floats on the surface, or sinks to the bottom, according as it is lighter or heavier than water. In distilling the seeds of Caraway and Fennel, the leaves of Peppermint, Spearmint, and Pennyroyal, and the berries of Pimento, the liquor which comes over with the oil is to be kept for use in the manner directed under the head of Distilled Waters." *Dub.*

The substances from which the volatile oils are extracted, may be employed either in the recent or dried state. Certain flowers, however, such as orange flowers and roses, must be used fresh, or preserved with salt, as they afford little or no oil after exsiccation. Most of the aromatic herbs also, as peppermint, spearmint, pennyroyal, and marjoram, are usually distilled while fresh, and are directed in this state by the London College; although it is thought by some, that when moderately dried, they yield a larger and more grateful product. Dried substances, before being submitted to distillation, require to be macerated in water till they are thoroughly penetrated by this fluid; and to facilitate the action of the water, it is necessary, that when of a hard or tough consistence, they should be properly comminuted by slicing, shaving, rasping, bruising, or other similar mechanical operation.

The water which is put with the subject of distillation into the alembic, answers the double purpose of preventing the decomposition of the vegetable matter by regulating the temperature, and of facilitating the volatilization of the oil, which, though in most instances it readily rises with the vapour of boiling water, requires when distilled alone, a considerably higher temperature, and is at the same time liable to be partially decomposed. Some oils, however, will not ascend readily with steam at 212°; and in the distillation of these it is customary to use water saturated with common salt, which does not boil under 230°. Others again may be volatilized with water at a temperature below the boiling point; and as heat exercises an injurious influence over the oils, it is desirable that the distillation should be effected at as low a temperature as possible. To prevent injury from heat it has been recommended to suspend the substance containing the oil in a basket, or to place it upon a perforated shelf, in the upper part of the alembic, so that it may be penetrated by the steam, without being in direct contact with the water. Another mode of effecting the same object, is to distil *in vacuo.* Dr. Duncan states, that the most elegant volatile oils he had ever seen were prepared in this manner by Mr. Barry, the inventor of the process.

The quantity of water added is not a matter of indifference. An excess above what is necessary, acts injuriously by holding the oil in solution, when the mixed vapours are condensed; and, if the proportion be very large, it is possible that no oil whatever may be obtained separate. On the contrary, if the quantity be too small, the whole of the oil will not be distilled; and there will be danger of the substance in the alembic adhering to the sides of the vessel, and thus becoming burnt. Enough water should always be added to cover the solid material, and prevent this latter accident. Dried plants require more water than those which are fresh and succulent. The whole amount of materials in the alembic should not exceed three-fourths of its capacity; as otherwise there would be danger of the liquor boiling over. The form of the alembic has a considerable influence over the quantity of water distilled, which depends more upon the extent of surface than the amount of liquid submitted to evaporation. By employing a high and narrow vessel, we may obviate the disadvantage of an excess of water. The broad shallow alembic, suitable for the distillation of alcohol and the spirituous liquors, will not answer so well in this case. Sometimes the proportion of oil contained in the substance employed is so small, that it is wholly dissolved in the water distilled, even though the proportion of the liquid in the alembic is not greater than is absolutely essential. In this case it is necessary to redistil the same water several times from fresh portions of the plant till the quantity of oil exceeds its solvent power. This process is called *cohobation.*

The more volatile oils pass with facility along with the steam into the neck of the common still; but some which are less volatile are apt to condense in the head, and thus return into the alembic. For the distillation of the latter, a still should be employed with a large and very low head, having a rim or gutter around its internal circumference, into which the oils may be received as they condense, and thence pass into the neck. As, after the distillation of any one oil, it is necessary that the apparatus should be thoroughly cleansed before being used for the preparation of another, it is better that the condensing tube should be straight, than spiral as in the ordinary still. It should be recollected, moreover, that certain oils, such as those of anise and fennel, become solid at a comparatively high temperature; and that in the distillation of these, the water employed for refrigeration should not be below 42° F.

The mixed vapours are condensed into a milky liquid, which is collected in a receiver, and after standing for some time separates into a clear solution of the oil in water, and into the oil itself, the latter floating on the surface, or sinking to the bottom, according as it is lighter or heavier than water. The distillation should be continued so long as the fluid which comes over has this milky appearance.

The last step in the process is to separate the oil from the water. For this purpose the *Florence receiver* may be used. This is a conical glass vessel, broad at the bottom, and narrow towards the top, and, very near its base, furnished with a tubulure or opening, to which is adapted, by means of a pierced cork, a bent tube so shaped as to rise perpendicularly to seven-eighths of the height of the receiver, then to pass off from it at right angles, and near the end to bend downwards. The condensed liquid being admitted through the opening in the top of the receiver, the oil separates, and rising to the top, occupies the upper narrow part of the vessel, while the water remains at the bottom and enters the tube affixed to the receiver. When the surface of the liquid attains in the receiver a higher level than the top of the tube, the water will necessarily begin to flow out through the latter, and may be received in bottles. The oil thus accumulates so long as the process continues; but it is evident that the plan is applicable only to the oils lighter than water. For the heavier oils, cylindrical vessels may be employed, to be renewed as fast as they are filled. But as all the water cannot be removed by these plans, it is necessary to resort to some other method of effecting a complete separation. An instrument called a *separatory* is usually employed for this purpose. It consists of a glass funnel, bulging at the top, where it is furnished with a stopper, and prolonged at the bottom into a very narrow tube. (See figure, page 693.) The lower opening being closed, the mixed liquids are introduced, and allowed to stand till they separate. The orifice at the bottom is then opened, and the stopper at top being a little loosened so as to admit the air, the heavier liquid slowly flows out; and may be separated to the last drop from the lighter, which floats above it. If the oil is heavier than water, it passes out of the separatory, if lighter, it remains within. Another mode of separating the oil, is to introduce into the vessel containing the two liquids, one end of a cord of cotton, the other end hanging out and terminating in a suitable receptacle beneath the level of that immersed in the liquid. The oil at top passes through the cord, and may thus be wholly removed. The last drops may be collected by pressing the cord between the fingers.

The water saturated with oil should be preserved for future distillations, as it can now dissolve no more of the oil, and will therefore yield a larger product.

When first procured, the oil has a disagreeable empyreumatic odour, from which it may be freed by allowing it to stand for some days in vessels loosely covered with paper. It should then be introduced into small opaque bottles, which should be well stopped, so as to exclude the air.

The volatile oils have the medical properties of the plants from which they are derived; and as their remedial application has been mentioned under the heads of these plants respectively, it will be unnecessary to treat of it in this place. They may be administered dropped on a lump of sugar; or triturated with at least ten times their weight of sugar, forming an *oleo-saccharum*, and then dissolved in water; or made into an emulsion with water, sugar, and gum Arabic. They are frequently kept dissolved in alcohol under the name of *essences*. W.

OLEUM ANISI. *U.S.*, *Lond.*, *Dub.* OLEUM VOLATILE PIMPINELLÆ ANISI. *Ed.* *Oil of Anise.*

Recluz obtained from fresh anise seeds from 2.125 to 2.48 per cent. of oil; from the dried, 3.125 per cent. The oil employed in this country is almost all imported. It is colourless or yellowish, with the peculiar odour and taste of the seed. At 50° it crystallizes in flat tables, and does not melt under 62°. Its. sp. gr. is variously stated from 0.9768 to 0.9903. Berzelius gives it 0.9857 at 77° F. It is soluble in all proportions in alcohol of 0.806; but alcohol of 0.840 dissolves at 77° only 42 per cent. It consists of two oils, one solid at ordinary temperatures and heavier than water (*stearoptene*), the other liquid and more volatile (*eleoptene*). It is said to be sometimes adulterated with spermaceti, wax, or camphor. The first two may be detected by their insolubility in cold alcohol, the last by its odour. The dose of the oil is from five to fifteen drops. Its comparative mildness adapts it to infantile cases. The *oil of star aniseed* (*oleum badiani*), which resembles it in flavour, is frequently substituted for it in this country.

Off. Prep. Syrupus Sarsaparillæ, *U.S.*; Tinctura Opii Camphorata, *U.S.*, *Dub.* W.

OLEUM ANTHEMIDIS. *Lond.* OLEUM VOLATILE ANTHEMIDIS NOBILIS. *Ed.* *Oil of Chamomile.*

This is never prepared, and little used, in this country. Baumé obtained thirteen drachms of the oil from eighty two pounds of the flowers. It has the peculiar smell of chamomile, with a pungent somewhat aromatic taste.

When recently distilled it is of a sky-blue colour, which changes to yellow on exposure. The sp. gr. of the English oil is said in be 0.9083. It has sometimes been used in spasm of the stomach, and as an adjunct to purgative medicines. The dose is from five to fifteen drops.

On the continent of Europe, an oil extracted from the *Matricaria Chamomilla* is employed under the name of oil of chamomile. It is dark blue, thick, and nearly opaque, becoming brown and unctuous by time. It has the odour of the plant from which it is derived, and an aromatic taste. W.

OLEUM CARI. *U.S.* Oleum Carui. *Lond., Dub.* *Oil of Caraway.*

This oil is prepared to a considerable extent by our distillers. The fresh seeds yield on an average about 4.7 per cent. (Recluz); but the product is very variable. The oil of caraway is somewhat viscid, of a pale yellow colour, with the odour and taste of the seeds. Its sp. gr. is 0.946 according to Baumé, 0.931 according to Brande. It is much used to impart flavour to medicines, and to correct their nauseating and griping effects. The dose is from one to ten drops.

Off. Prep. Confectio Scammoneæ, *Lond., Dub.;* Electuarium Sennæ, *Dub.;* Pilulæ Aloës Compositæ, *Lond., Dub.* W.

OLEUM CHENOPODII. *U.S.* *Oil of Wormseed.*

This oil is peculiar to the United States. It is of a light yellow colour when recently distilled, but becomes deeper yellow, and even brownish by age. It has in a high degree the peculiar flavour of the plant. Its sp. gr. is 0.908. It is used as an anthelmintic, in the dose of from four to eight drops for a child, repeated morning and evening for three or four days, and then followed by a brisk cathartic. W.

OLEUM FŒNICULI. *U.S.* Oleum Fœniculi Dulcis. *Dub.* *Oil of Fennel.*

Fennel seeds yield about 2.5 per cent. of oil. That used in this country is imported. It is colourless or yellowish, with the odour and taste of the seeds. Its sp. gr. is 0.997. It congeals below 50° into a crystalline mass, separable by pressure into a solid and liquid oil (*stearoptene* and *eleoptene*), the former heavier than water, and less volatile than the latter, which rises first when the oil is distilled. As found in the shops, therefore, the oil of fennel is not uniform; and Dr. Montgomery found that a specimen which he examined did not congeal at 22°. The dose is from five to fifteen drops. W.

OLEUM GAULTHERIÆ. *U.S.* *Oil of Partridge-Berry.*

This oil is known only in the United States. It is directed by the Pharmacopœia to be prepared from the leaves of the *Gaultheria procumbens;* but the whole plant is usually employed. It is supposed to exist also in the bark of the *Betula lenta*, the root of the *Polygala paucifolia*, and the roots and stems of the *Spiræa ulmaria*, *Spiræa lobata*, and *Gaultheria hispidula*, which have its peculiar flavour. The oil of partridge-berry has a brownish-yellow colour, a sweetish, slightly pungent, peculiar taste, and a very agreeable characteristic odour, by which it may be readily distinguished from all other oils. It is the heaviest of the known essential oils, having the sp. gr. 1.17. (*Journ. of the Phil. Col. of Pharm.* iii. 199.) This affords an easy method of ascertaining its purity. It is used chiefly on account of its pleasant flavour, to cover the taste of other medicines.

Off. Prep. Syrupus Sarsaparillæ, *U.S.* W.

OLEUM HEDEOMÆ. *U.S. Oil of Pennyroyal.*

This, though analogous in properties to the European oil of pennyroyal, is derived from a distinct plant—the *Hedeoma pulegioides*—peculiar to North America. It has a light yellow colour, with the odour and taste of the herb. Its sp. gr. is 0.948. It may be used as a remedy in flatulent colic and sick stomach, to correct the operation of nauseating or griping medicines, and to impart flavour to mixtures. The dose is from two to ten drops. W.

OLEUM JUNIPERI. *U.S., Lond., Dub.* OLEUM VOLATILE JUNIPERI COMMUNIS. *Ed.* *Oil of Juniper.*

The proportion of oil which juniper berries afford is stated differently by different authors, from 0.78 to 5 per cent. The greatest quantity obtained by Recluz was 2.34 parts from 100. The berries are most productive when bruised. The oil of juniper consumed in this country is brought from Europe. It is colourless, or of a light greenish-yellow, with a terebinthinate odour, and a hot acrid taste. Its sp. gr. is 0.911. It is not very soluble in alcohol. The oil of turpentine is often fraudulently added, but may be detected by the specific gravity of the mixture, which is considerably less than that of the unadulterated oil of juniper.

This oil is stimulant, carminative, and diuretic; and may be employed advantageously in debilitated dropsical cases, in connexion with other medicines, especially with digitalis. It is this oil which imparts to Holland gin its peculiar flavour and tendency to the kidneys. The dose is from five to fifteen drops two or three times a day, and may be considerably increased. W.

OLEUM LAVANDULÆ. *U.S., Lond., Dub.* OLEUM VOLATILE LAVANDULÆ SPICÆ. *Ed.* *Oil of Lavender.*

Dried lavender flowers yield on an average about 1.5 per cent. of a very fluid, lemon-yellow oil, having the fragrance of the flowers, and an aromatic, burning taste. That met with in commerce has the sp. gr. 0.898 at 68° F., which is reduced to 0.877 by rectification. (*Berzelius.*) According to Brande, the sp. gr. of the oil obtained from the whole herb is 0.9206. Alcohol of 0.830 dissolves the oil of lavender in all proportions; that of 0.887 only 42 per cent. (*Berzelius.*) Proust states, that when allowed to stand in imperfectly stopped bottles, it lets fall a crystalline deposite (*stearoptene*), which he considers identical with camphor, and which often amounts to one-fourth of the weight of the oil. It is said that the portion of oil first distilled is most agreeably fragrant, and is often kept separate, and sold at a higher price. The oil of lavender is used chiefly as a perfume, though possessed of carminative and stimulant properties, and sometimes useful in cases of nervous languor and headach. The dose is from one to five drops.

The *oil of spike* is procured from the broad-leaved variety of the lavender, which grows wild in Europe, the *Lavandula Spica* of De Candolle. Its odour is less fragrant than that of the common oil of lavender, and is somewhat analogous to that of the oil of turpentine, with which it is said to be often adulterated. It is much used by artists in the preparation of varnishes.

Off. Prep. Spiritus Ammoniæ Succinatus, *Lond.* W.

OLEUM MENTHÆ PIPERITÆ. *U.S., Lond.* OLEUM VOLATILE MENTHÆ PIPERITÆ. *Ed.* OLEUM MENTHÆ PIPERITIDIS. *Dub.* *Oil of Peppermint.*

Peppermint varies exceedingly in the quantity of oil which it affords.

Four pounds of the fresh herb yield, according to Baumé, from a drachm and a half to three drachms of the oil. The product is generally less than one per cent. This oil is largely distilled in the United States. It is of a greenish-yellow colour, a strong aromatic odour, and a warm, camphorous, very pungent taste, succeeded, when air is admitted into the mouth, by a sense of coolness. Its sp. gr. is stated differently from 0.907 to 0.920. Upon long standing it deposites a *stearoptene*, considered by Proust as identical with camphor. According to Giese, it is only the oil distilled from the herb gathered when in flower and dried, that yields this crystalline precipitate. Berzelius states, that at—8° F. it deposites small capillary crystals.

The oil of peppermint is stimulant and carminative, and is much used in flatulence, nausea, spasmodic pains of the stomach and bowels, and as a corrigent or adjuvant of other medicines. The dose is from one to three drops, and is most conveniently given rubbed up with sugar and then dissolved in water. The oil is also very frequently employed in the form of *essence of peppermint*, prepared by dissolving two fluidounces in a pint of alcohol, and given upon sugar in the dose of ten or twenty drops.

Off. Prep. Aqua Menthæ Piperitæ, *U.S.;* Pilulæ Rhei Compositæ, *Ed.;* Pilulæ Sulphatis Ferri Comp., *Ed.;* Spiritus Menthæ Piperitæ, *Lond.*, *Dub.* W.

OLEUM MENTHÆ VIRIDIS. *U.S.*, *Lond.*, *Dub.* OLEUM VOLATILE MENTHÆ VIRIDIS. *Ed.* *Oil of Spearmint.*

According to Lewis, ten pounds of spearmint yield an ounce of oil; by others the product is stated not to exceed one part from five hundred. The oil is largely distilled in this country. It is greenish when recently prepared, but becomes red with age, and ultimately almost of a mahogany colour. Its flavour is analogous to that of the oil of peppermint, but is less agreeable and less pungent. Its sp. gr., according to Lewis, is 0.975, according to Brande 0.9394. It is used for the same purposes as the oil of peppermint, in the dose of from two to five drops. An *essence of spearmint* is prepared by dissolving two fluidounces of the oil in a pint of alcohol, and may be given in the quantity of from twenty to forty drops, upon a lump of sugar.

Off. Prep. Aqua Menthæ Viridis, *U.S.*, *Lond.*, *Dub.;* Infusum Menthæ Compositum, *Dub.;* Spiritus Menthæ Viridis, *Lond.*, *Dub.* W.

OLEUM MONARDÆ. *U.S.* *Oil of Horsemint.*

This is prepared by our distillers from the fresh herb of the *Monarda punctata*. It has a reddish-amber colour, a fragrant odour, and a warm, very pungent taste. Applied to the skin it acts as a powerful rubefacient, quickly producing heat, pain, redness, and even vesication. This property of the oil was made known to the profession by Dr. Atlee of Philadelphia, who employed it externally with advantage in low forms of typhus fever, cholera infantum, chronic rheumatism, and other affections in which rubefacients are indicated. In ordinary cases it should be diluted before being applied. It may be given internally as a stimulant and carminative, in the dose of two or three drops mixed with sugar and water. W.

OLEUM ORIGANI. *U.S.*, *Lond.*, *Dub.* *Oil of Origanum.*

This is obtained from the common marjoram, *Origanum vulgare*, and is frequently called *oil of marjoram*. The plant varies exceedingly in the proportion which it affords. The mean product may be stated at from four to six parts from a thousand. The recent oil, when properly prepared, is of a yellow colour; but if too much heat is used in the distillation, it is said to be reddish, and it acquires the same tint by age. It has the odour of the plant, and a hot acrid taste. Its sp. gr., according to Lewis, is 0.940, according to Brande 0.909. It is sometimes used as an external irritant, and to allay the pain of toothach, by being introduced, on lint or cotton, into the cavity of a carious tooth. It is not employed internally.

Off. Prep. Linimentum Saponis Camphoratum, *U.S.* W.

OLEUM VOLATILE ORIGANI MARJORANÆ. *Ed.* *Oil of Sweet Marjoram.*

It is somewhat doubtful, whether the Edinburgh College did not intend to direct, under this title, the oil of marjoram (*Oleum Origani*); at least the terms are considered as identical in their signification by the authors of the British Dispensatories. The oils of the two plants, however, are entirely distinct. The sweet marjoram yields when distilled from 2.5 to 6 parts of oil out of 1000 of the plant. This oil is of a lemon-yellow colour, light, and camphorous, and deposites upon long standing a substance supposed to be identical with camphor. It is not used in this country. W.

OLEUM PIMENTÆ. *U.S.*, *Lond.*, *Dub.* OLEUM VOLATILE MYRTI PIMENTÆ. *Ed.* *Oil of Pimento.*

The berries yield from 1 to 4 per cent. of oil, which, as found in the shops, has a brownish-red colour, and the odour and taste of pimento, though warmer and more pungent. It is said, when freshly distilled, to be colourless or yellowish. Nitric acid reddens it. Bonastre states that it combines with salifiable bases like the oil of cloves. Its sp. gr. is 1.021. It may be given for the same purposes with the other aromatic stimulant oils. The dose is from three to six drops.

Off. Prep. Emplastrum Aromaticum, *Dub.* W.

OLEUM PULEGII. *Lond.*, *Dub.* *Oil of European Pennyroyal.*

About 1 part of this oil on an average is obtained from 100 parts of the plant. When freshly distilled it is yellowish, but becomes reddish by age. Its sp. gr. is, according to Lewis, 0.978, to Brande 0.939. It possesses medical properties similar to those of the oil of peppermint; but is moldes used in this country. The dose is from one to five drops.

Off. Prep. Aqua Pulegii, *Lond.*, *Dub.*; Spiritus Pulegii, *Lond.*, *Dub.*

OLEUM ROSMARINI. *U.S.*, *Lond.* OLEUM VOLATILE RORISMARINI OFFICINALIS. *Ed.* OLEUM RORISMARINI. *Dub.* *Oil of Rosemary.*

The fresh leaves of rosemary yield, according to Baumé, 26 per cent. of oil; but the product is stated very differently by different authors. This oil is colourless, with an odour similar to that of the plant, though less agreeable. Its sp. gr. is 0.911, but is reduced to 0.8886 by rectification. It is soluble in all proportions in alcohol of 0.830; but requires for solution at 64°, forty parts of alcohol of the sp. gr. 0.887. (*Berzelius.*) Kept in bottles imperfectly stopped, it deposites a *stearoptene*, which is considered identical with camphor, and the proportion of which, according to Proust, amounts sometimes to one-tenth of the oil. Bucholz states that it affords camphor when digested with from one half its weight to an equal weight of potassa, and distilled. It is said to be sometimes adulterated with the oil of turpentine, which may be detected by mixing the suspected liquid with an equal volume of pure alcohol. The oil of rosemary is dissolved, and that of turpentine left. This oil is possessed of stimulant properties, but is employed chiefly as an ingredient of rubefacient liniments. The dose is from three to six drops.

Off. Prep. Alcohol Ammoniatum Aromaticum, *U.S., Ed.;* Linimentum Saponis Camphoratum, *U.S.;* Spiritus Rosmarini, *U.S., Lond., Dub.;* Tinctura Saponis Camphorata, *U.S., Ed.;* Tinctura Saponis et Opii, *Ed.* W.

OLEUM RUTÆ. *Dub.* *Oil of Rue.*

Rue yields a very small proportion of a yellow or greenish oil, which becomes brown with age. It has the strong unpleasant odour of the plant, and an acrid taste. According to Dr. A. T. Thomson it congeals at 40°, but Dr. Montgomery found it to remain liquid at 28° F. It is stimulant and supposed to be antispasmodic; and has been given in hysteria, convulsions, and amenorrhœa. The dose is from two to five drops. W.

OLEUM SABINÆ. *Dub.* OLEUM VOLATILE JUNIPERI SABINÆ. *Ed.* *Oil of Savine.*

Savine is very abundant in volatile oil. The fresh leaves yield, according to Hoffmann and Murray, between 15 and 16 per cent.; the dried are much less productive. The oil is yellow, limpid, light, strongly odorous, and of an exceedingly acrid taste. It is stimulant, emmenagogue, and actively rubefacient; and may be given for the same purposes as the plant in substance. It has been much employed empyrically in amenorrhœa, and with a view to produce abortion, and in some instances with fatal effects. The dose is from two to five drops. W.

OLEUM SASSAFRAS. *U.S., Dub.* OLEUM VOLATILE LAURI SASSAFRAS. *Ed.* *Oil of Sassafras.*

The proportion of oil yielded by the root of sassafras is variously stated from 1.25 to 2 per cent. The bark of the root, directed by the U.S. Pharmacopœia, would afford a larger quantity. This oil is of a yellow colour, becoming reddish by age. It has the fragrant odour of sassafras, with a warm pungent aromatic taste. It is among the heaviest of the volatile oils, having the sp. gr. 1.094. According to Bonastre, it separates, by agitation with water, into two oils, one lighter, the other heavier than water. Berzelius states that the first is often nothing more than oil of turpentine existing as an adulteration in the oil of sassafras. Nitric acid colours it red, and fuming nitric acid inflames it more readily than most other oils. It has the useful property of dissolving caoutchouc. When kept for a long time it deposites transparent crystals, having the same odour as the liquid oil. It is stimulant, carminative, and supposed to be diaphoretic; and may be employed for the same purposes with the bark from which it is derived. The dose is from two to ten drops.

Off. Prep. Syrupus Sarsaparillæ, *U.S.* W.

OLEUM SUCCINI. *U.S., Ed., Dub.* *Oil of Amber.*

"Take of Amber, in powder, *any quantity*. Put the Amber, previously mixed with an equal weight of sand, into a glass retort, which is to be only half filled; then distil, by means of a sand-bath, with a gradually increasing heat, an acid liquor, an oil, and a concrete acid impregnated with oil. Separate the oil from the other matters, and preserve it in well stopped bottles." *U.S.*

The unrectified oil of amber is not among the preparations directed by the *London College.* The *Edinburgh* and *Dublin Colleges* obtain it by the same process by which they procure succinic acid. (See *Acidum Succinicum.*)

The amber in this process undergoes decomposition, and affords, among other products, an empyreumatic oil which floats in the receiver upon the surface of an acid liquor. The heat requisite for the complete decomposition of the amber cannot be supported by a glass retort; and in order that all the oil which it is capable of yielding may be collected, the distillation should be performed in a tubulated iron or earthenware retort, which may be placed immediately upon the fire. The sand is added to prevent the amber from swelling too much. The oil may be separated from the acid liquor by means of the separating funnel. As first procured, it is a thick, very dark coloured liquid, of a peculiar strong empyreumatic odour. In this state it is occasionally employed as a liniment; but for internal use it should always be rectified. W.

OLEUM SUCCINI RECTIFICATUM. *U.S., Dub.* OLEUM SUCCINI. *Lond.* OLEUM SUCCINI PURISSIMUM. *Ed.* *Rectified Oil of Amber.*

"Take of Oil of Amber *a pint;* Water *six pints.* Distil them from a glass retort, till four pints of the Water shall have passed over into the receiver; then separate from the Water the Oil which has been distilled, and preserve it in well stopped bottles." *U.S.*

The *Edinburgh College* employs one part of oil of amber and six of water; the *Dublin*, a pound of the former and six pints of the latter; both distil until two-thirds of the water has passed into the receiver, and then separate the oil.

"Put amber into an alembic, and distil from a sand-bath, with a heat gradually increased, an acid liquor, an oil, and a salt contaminated with oil; then distil the oil a second and a third time." *Lond.*

By successive distillations the oil of amber is rendered thinner and more limpid, till at length it is obtained colourless. The first portions which distil are less coloured than those which follow, and may be separated for keeping, while the remainder is submitted to another distillation. For practical purposes, however, the oil is sufficiently pure when once redistilled, as directed in the processes of the U.S., Edinburgh, and Dublin Pharmacopœias. As usually found in the shops, the rectified oil is of a light yellowish-brown or amber colour. When quite pure it is colourless, as fluid as alcohol, of sp. gr. 0.758 at 75°, and boils at 186°. It has a strong, peculiar, unpleasant odour, and a hot, acrid taste. It imparts these properties in some degree to water without being perceptibly dissolved. It is soluble in eight parts of alcohol of the sp. gr. 0.847 at 55°, in five parts of the sp. gr. 0.825, and in all proportions in absolute alcohol. The fixed oils unite with it. On exposure to the light and air, it slowly changes in colour and consistence, becoming ultimately black and solid.

Medical Properties and Uses. Rectified oil of amber is stimulant and antispasmodic; and occasionally promotes the secretions, particularly that of urine. It has been employed with advantage in amenorrhœa, and in various spasmodic and convulsive affections, as tetanus, epilepsy, hysteria, hooping cough, and infantile convulsions from intestinal irritation, &c. The dose is from five to fifteen drops, diffused in some aromatic water by means of sugar and gum Arabic. Externally applied, the oil is rubefacient, and is considerably employed as a liniment in chronic rheumatism and palsy, and in certain spasmodic disorders, as hooping cough and infantile convulsions. In the latter affection it should be rubbed along the spine, and is highly recommended by Dr. Parrish of Philadelphia, mixed with an equal measure of laudanum and diluted with three or four parts of olive oil and of brandy.

Off. Prep. Spiritus Ammoniæ Succinatus, *Lond.* W.

OLEUM TEREBINTHINÆ RECTIFICATUM. *Lond., Dub.* OLEUM VOLATILE PINI PURISSIMUM. *Ed.* *Rectified Oil of Turpentine.*

"Take of Oil of Turpentine *a pint;* Water *four pints.* Distil the Oil." *Lond.*

"Take of Oil of Turpentine *one part;* Water *four parts.* Distil as long as any Oil comes over." *Ed.*

"Take of Oil of Turpentine *two pints;* Water *four pints.* Distil a pint and a half of the Oil." *Dub.*

The oil of Turpentine becomes impure by exposure, in consequence of the absorption of oxygen and the production of resin. From this it may be freed by distillation, as above directed, or by the agency of alcohol. (See *Oleum Terebinthinæ.*) The process for distilling it is attended with some inconvenience, in consequence of the great inflammability of the vapour, and its rapid formation, which causes the liquid to boil over. In this country, the apothecary can almost always purchase the oil sufficiently pure for medical use without the necessity of rectifying it. The presence of a small proportion of resin does not interfere with its efficiency as a medicine. W.

PILULÆ.

Pills.

These are small globular masses of a size convenient for swallowing. They are well adapted for the administration of medicines which are unpleasant to the taste or smell, or insoluble in water, and do not require to be given in large doses. Deliquescent substances should not be made into pills, and those which are efflorescent should be previously deprived of their water of crystallization. Care should also be taken not to combine materials, the mutual reaction of which may result in a change of form.

Some substances have a consistence which enables them to be made immediately into pills. Such are the softer extracts and certain gum-resins; and the addition of a little water to the former, and a few drops of spirit to the latter, will give them the requisite softness and plasticity, if previously wanting. Substances which are very soft, or in the liquid state, are formed into the pilular mass by incorporation with dry and inert powders, such as crumb of bread, wheat flour, starch, and powdered gum Arabic. Powders must be mixed with soft solid bodies, as extracts, confections, soap, &c., or with tenacious liquids, as syrup, molasses, honey, or mucilage. Heavy metallic powders are most conveniently made into pills with the former; light vegetable powders with the latter. Mucilage is very often used; but pills made with it are apt when kept to become hard and of difficult solubility in the liquors of the stomach, and if metallic substances are mixed with it, the mass does not work well. A mixture of syrup and powdered gum Arabic is not subject to the same inconveniences, and is an excellent material for the formation of pills. Many powders require only the addition of water. Such are all those which contain ingredients capable of forming an adhesive or viscid solution with this liquid. Care should always be observed, that the matter added be not incompatible with the main ingredients of the pill.

The materials should be accurately mixed together, and beat in a mortar till formed into a perfectly uniform and plastic mass. This should be of such a consistence, that the pills may preserve their form, without being so hard as to resist the solvent power of the gastric liquors. As pills often become very hard by time, it is convenient, in some instances, to keep the mass in a state fit to be divided when wanted for use. This may be done by wrapping it in bladders, putting it in covered pots, and occasionally moistening it as it becomes dry.

The mass, having been duly prepared, is made into pills by rolling it with a spatula into a cylinder of precisely the same thickness throughout, and of a length corresponding to the number of pills required. It is then divided as equally as possible by the hand, or more accurately by a machine made for the purpose. The pills receive a spherical form by being rolled between the fingers. In order to prevent their adhesion to one another, or to the sides of the vessel in which they may be placed, it is customary to agitate them with some dry powder, which gives them an external coating, that serves also to conceal their taste. For this purpose, carbonate of magnesia, starch, or powdered liquorice root may be used. Carbonate of magnesia is sometimes incompatible with one of the ingredients of the pills, starch is almost too light, and liquorice root will, as a general rule, be found the best. The powder of *Lycopodium* is much employed on the continent of Europe; and it was formerly the custom to give the pill a coating of gold or silver leaf.

Though the U.S. Pharmacopœia, in every instance, orders the mass to be divided into pills; yet it should be understood rather as indicating the number of pills to be made from a certain quantity of the mass when particular directions are not given by the physician, than as requiring the division to be made immediately after the materials have been mixed. It will generally be found convenient by the apothecary to keep a portion of the mass undivided. W.

PILULÆ ALOES. *U.S.* PILULÆ ALOETICÆ. *Ed.* *Aloetic Pills.*

"Take of Aloes, in powder, Soap, each, *an ounce.* Beat them with water so as to form a mass, to be divided into two hundred and forty pills." *U.S.*

The *Edinburgh College* directs equal quantities of aloes and soap to be beat with simple syrup into a mass fit for forming pills.

The soap, in this formula, not only serves to impart a proper pilular consistence to the aloes, but is thought to qualify its operation, and diminish its liability to irritate the rectum. Five pills, containing ten grains of aloes, may be given with a view to their purgative effect; but the preparation is usually employed as a laxative in cases of habitual costiveness, in the quantity of one, two, or three pills, taken before breakfast, before dinner, or at bedtime. W.

PILULÆ ALOES COMPOSITÆ. *Lond.*, *Dub.* *Compound Pills of Aloes.*

"Take of Socotrine Aloes [Hepatic Aloes, *Dub.*], in powder, *an ounce;* Extract of Gentian *half an ounce;* Oil of Caraway *forty minims;* Simple Syrup *a sufficient quantity.* Beat them together, till they are thoroughly incorporated." *Lond.*

A reaction takes place between the aloes and extract of gentian when rubbed together, which renders the mass so soft as sometimes to require the addition of a light powder. The use of syrup is therefore unnecessary and improper. This combination is well adapted as a laxative to the costiveness of sedentary and dyspeptic persons. The dose is from five to twenty grains, according to the degree of effect desired.* W.

---

* The following is the formula for the aloetic pills usually called *dinner pills, or Lady Webster's pills.* They are the *pilulæ stomachicæ* of the fifth edition of the Paris Codex, A.D. 1758. Take of the best Aloes six drachms; Mastich and Red Roses, each, two

PILULÆ ALOES ET ASSAFŒTIDÆ. *U.S., Ed.* *Pills of Aloes and Assafetida.*

"Take of Aloes, in powder, Assafetida, Soap, each. *half an ounce.* Beat them with water so as to form a mass, to be divided into one hundred and eighty pills. *U.S.*

The *Edinburgh College* takes equal parts of Socotrine aloes, assafetida, and soap, and beats them into a mass with mucilage of gum Arabic.

These pills are peculiarly adapted, by the stimulant and carminative properties of the assafetida, to cases of costiveness attended with flatulence and debility of the digestive organs. Each pill contains about four grains of the mass. From two to five may be given for a dose. W.

PILULÆ ALOES ET MYRRHÆ. *U.S., Ed.* PILULÆ ALOES CUM MYRRHA. *Lond., Dub.* *Pills of Aloes and Myrrh.*

"Take of Aloes, in powder, *two ounces;* Myrrh, in powder, *an ounce;* Saffron *half an ounce;* Syrup *a sufficient quantity.* Beat the whole together so as to form a mass, to be divided into four hundred and eighty pills." *U.S.*

The directions of the *Edinburgh* Pharmacopœia correspond with the above, Socotrine aloes being particularly indicated. Those of the *London* and *Dublin* Pharmacopœias differ only in the proportion of saffron, which is doubled, Socotrine aloes being directed by the former, and hepatic aloes by the latter.

This composition has been long in use, and is generally known by the name of *Rufus's pills.* It is employed as a warm stimulant cathartic in debilitated states of the system, attended with constipation and retention or suppression of the menses. From three to six pills, or from ten to twenty grains of the mass may be given for a dose. W.

PILULÆ AMMONIARETI CUPRI. *Ed.* *Pills of Ammoniaret of Copper.*

"Take of Ammoniaret of Copper, in fine powder, *sixteen grains;* Crumb of Bread *four scruples;* Water of Carbonate of Ammonia *a sufficient quantity.* Beat them into a mass, to be divided into thirty-two equal pills. *Ed.*

This is a convenient form for administering ammoniated copper. One pill, containing half a grain of the preparation of copper, may be given night and morning; and the dose gradually increased to five or six pills. W.

PILULÆ ASSAFŒTIDÆ. *Assafetida Pills.*

"Take of Assafetida *an ounce and a half;* Soap *half an ounce.* Beat them with water so as to form a mass, to be divided into two hundred and forty pills." *U. S.*

drachms; Syrup of Wormwood sufficient to form a mass, to be divided into pills of three grains each. Common syrup may be substituted for the syrup of wormwood. One or two of these pills taken shortly before a meal, will usually produce one free evacuation.

The Philadelphia College of Pharmacy has adopted formulæ for the compound aloetic preparations commonly called *Hooper's* and *Anderson's pills*, of which the following are copies.

"*Hooper's female pills.* ℞ Aloes Barbadensis ℥viij., Ferri Sulphatis Exsiccati ℥ij., ʒiss., *vel* Ferri Sulphatis Crystal. ℥iv., Extracti Hellebori Nigri ℥ij., Myrrhæ, ℥ij., Saponis ℥ij., Canellæ in pulv. tritæ ℥j., Zingiberis in pulv. trit. ℥j.—Beat them well together into a mass with water, and divide into pills, each containing two and a half grains." *Journ. of the Phil. Col. of Pharm.* v. 25.

"*Anderson's Scots' Pills.* ℞ Aloes Barbadensis ℥xxiv., Saponis ℥iv., Colocynthidis ℥j., Gambogiæ ℥j., Olei Anisi f℥ss. Let the aloes, colocynth, and gamboge be reduced to a very fine powder, then beat them and the soap with water into a mass, of a proper consistence to divide into pills, each containing three grains." *Ibid.*

Each of these pills contains three grains of the gum-resin. They are a very convenient form for administering assafetida, the unpleasant odour and taste of which render it very offensive in the liquid state. W.

PILULÆ CATHARTICÆ COMPOSITÆ. *U.S.* *Compound Cathartic Pills.*

"Take of Compound Extract of Colocynth *half an ounce;* Extract of Jalap, in powder, Mild Chloride of Mercury [Calomel], each, *three drachms;* Gamboge, in powder, *two scruples.* Mix the powders together; then with water form them into a mass, which is to be beat with the Extract of Colocynth, and divided into one hundred and eighty pills." *U. S.*

This cathartic compound was first made officinal in the last edition of the U.S. Pharmacopœia. It was intended to combine smallness of bulk with efficiency and comparative mildness of purgative action, and a peculiar tendency to the biliary organs. Such an officinal preparation was much wanted in this country, in which bilious fevers and other complaints attended with congestion of the liver and portal circle generally, so much abound. The object of smallness of bulk was accomplished by employing extracts and the more energetic cathartics; that of a peculiar tendency to the liver, by the use of calomel; and that of efficiency with mildness of operation, by the union of several powerful purgatives. It is a fact abundantly proved by experience, that drastic cathartics become milder by combination, without losing any of their purgative power. Nor is it difficult, in this case, to reconcile the result of observation with physiological principles. Cathartic medicines act on different parts of the alimentary canal and organs secreting into it. In small doses, both the irritation which they occasion and their purgative effect are proportionably lessened. If several are administered at the same time, each in a diminished dose, it is obvious that the combined purgative effect of all will be experienced, while the irritation, being feeble in each part affected, and diffused over a larger space, will be less sensible to the patient, and will more readily subside. In the compound cathartic pills, most of the active purgatives in common use are associated together in proportions corresponding to their respective doses, so that an excess of any one ingredient is guarded against, and violent irritation from this cause prevented. The name of the preparation may at first sight seem objectionable, as it might be applied to any compound pills possessing cathartic properties; but when it is considered that the ingredients cannot all be expressed in the title, and no one is sufficiently prominent to give a designation to the whole, and that the preparation is intended as the representative of numerous cathartics, and calculated for a wide range of application, the name will not be considered an inexcusable deviation from ordinary medical nomenclature.

Three of the pills, containing $10\frac{2}{3}$ grains of the mass are a dose for an adult. In this quantity are four grains of compound extract of colocynth, three of extract of jalap, three of calomel, and two-thirds of a grain of gamboge. A single pill will generally be found to operate as a mild laxative. In a full dose, the preparation acts vigorously on the bowels, producing bilious stools, generally without much pain or disorder of the stomach. It may be employed in most instances where a brisk cathartic is required; but is particularly applicable to the early stages of bilious fevers, to hepatitis, jaundice, and all those derangements of the alimentary canal or of the general health which depend on congestion of the portal circle. W.

PILULÆ COLOCYNTHIDIS COMPOSITÆ. *Ed. Dub.* *Compound Pills of Colocynth.*

"Take of Socotrine Aloes, Scammony, each, *eight parts;* Pulp of Colocynth *four parts;* Oil of Cloves, Sulphate of Potassa, each, *one part.* Reduce the Aloes and Scammony, with the Sulphate, to powder; then mix in the Colocynth rubbed to a very fine powder, and the Oil; lastly, beat the whole into a proper mass with Mucilage of Gum Arabic." *Ed.*

"Take of Hepatic Aloes, Scammony, each, *an ounce;* Pulp of Colocynth *half an ounce;* Castile Soap *two drachms;* Sulphate of Potassa, Oil of Cloves, each, *a drachm;* Molasses *a sufficient quantity.* Reduce the Aloes and Scammony to powder with the Sulphate of Potassa; then mix the Pulp of Colocynth and the Oil; and lastly, rub all together into a mass with the Soap and Molasses." *Dub.*

The sulphate of potassa, in these formulæ, is intended to promote the more complete division of the aloes and scammony. The preparation is actively cathartic in the dose of from eight to sixteen grains. W.

PILULÆ COPAIBÆ. *U. S.* *Pills of Copaiba.*

Take of Copaiba *two ounces;* Magnesia, recently prepared, *a drachm.* Mix them, and set the mixture aside till it concretes into a pilular mass, which is to be divided into two hundred pills." *U. S.*

When copaiba is mixed with pure magnesia, it gradually loses its fluid consistence, forming at first a soft tenacious mass, and ultimately becoming dry, hard, and brittle. The quantity of magnesia, and the length of time requisite for the production of this change, vary with the condition of the copaiba, being greater in proportion to the fluidity of this substance, or, in other words, to the amount of volatile oil which it contains. The quantity of magnesia directed by the Pharmacopœia, one-sixteenth of the weight of the copaiba, is sufficient to solidify the latter, as it is often found in the shops, in the course of six or eight hours; but when the copaiba is fresh, or has been kept in closely stopped bottles, and retains, therefore, nearly the whole of its volatile oil, it is necessary either to augment the proportion of magnesia, or to expose the mixture for a much longer time, or to diminish the volatile oil of the copaiba by evaporation. According to M. Fauré, the magnesia combines chemically with the resin, but in relation to the volatile oil, acts merely as an absorbent; for when the solidified mass is submitted to the action of boiling alcohol, a part is dissolved, abandoning the magnesia with which it was mixed, while the resin combined with another portion of the earth remains undissolved. (*Journ. de Pharm.* xvii. 105.) In the preparation of the pills, care should be taken to divide the mass before it has become too hard.

The advantage of this preparation is, that the copaiba is brought to the state of pill with little increase of its bulk. Each pill contains nearly five grains of copaiba, and from two to six may be taken for a dose twice or three times a day. W.

PILULÆ FERRI COMPOSITÆ. *U.S., Lond., Dub.* *Compound Pills of Iron.*

"Take of Myrrh, in powder, *two drachms;* Carbonate of Soda, Sulphate of Iron, each, *a drachm;* Syrup *a sufficient quantity.* Rub the Myrrh with the Carbonate of Soda; then add the Sulphate of Iron, and again rub them; lastly, beat them with the Syrup so as to form a mass, to be divided into eighty pills." *U.S.*

The directions of the British Colleges are essentially the same as the above. The *London* and *Dublin Colleges* order a drachm of brown sugar without syrup; but the reaction of the materials in our climate does not always produce sufficient moisture to give the mass a pilular consistence. The direction for dividing the mass into pills is peculiar to our Pharmacopœia.

This preparation is closely analogous to the Mistura Ferri Composita in properties and composition. It is a good emmenagogue and antihectic tonic. From two to six pills may be given at a dose, three times a day. W.

PILULÆ GALBANI COMPOSITÆ. *Lond., Dub.* PILULÆ ASSÆFŒTIDÆ COMPOSITÆ. *Ed.* *Compound Pills of Galbanum.*

"Take of Galbanum *an ounce;* Myrrh, Sagapenum, each, *an ounce and a half;* Assafetida *half an ounce;* Simple Syrup *a sufficient quantity.* Beat them together till they are thoroughly incorporated." *Lond.*

The *Dublin College* gives the same directions, substituting molasses for the syrup. The *Edinburgh College* takes of assafetida, galbanum, and myrrh, each, *eight parts,* and of rectified oil of amber *one part;* and beats them into a mass with simple syrup.

This compound is given as an antispasmodic and emmenagogue in chlorosis and hysteria. The dose is from ten to twenty grains. W.

PILULÆ GAMBOGIÆ COMPOSITÆ. *Ed., Dub.* PILULÆ CAMBOGIÆ COMPOSITÆ. *Lond.* *Compound Pills of Gamboge.*

"Take of Gamboge, in powder, *a drachm;* Socotrine Aloes, in powder, *a drachm and a half;* Ginger, in powder, *half a drachm;* Soap *two drachms.* Mix the powders together; then add the Soap, and beat the whole together till they are thoroughly incorporated." *Lond.*

The *Dublin* formula differs from the above only in the use of hepatic instead of Socotrine aloes, and in the addition of molasses to impart more readily the pilular consistence.

The *Edinburgh College* takes of gamboge, Socotrine aloes, and compound powder of cinnamon (*aromatic powder*), each, *a drachm,* and of soap *two drachms;* and proceeds in the manner ordered by the London College.

This is an active purgative pill; and may be given in the dose of ten or fifteen grains. The formula is that of Dr. George Fordyce simplified. W.

PILULÆ HYDRARGYRI. *U.S., Lond., Ed., Dub.* *Mercurial Pills. Blue Pills.*

"Take of Purified Mercury *an ounce;* Confection of Roses *an ounce and a half;* Liquorice Root, in powder, *half an ounce.* Rub the mercury with the Confection till all the globules disappear; then add the Liquorice Root and beat the whole into a mass, to be divided into four hundred and eighty pills." *U.S.*

The process of the *London College* is the same with the above, one quarter only of the quantity of materials being used. The *Dublin* process differs from the London only in substituting extract of liquorice root for the root itself. Neither of these Colleges orders the mass to be divided into pills.

"Take of Purified Mercury, Conserve of Red Roses, each, *an ounce;* Starch *two ounces.* Triturate the Mercury with the Conserve, in a glass mortar, till the globules disappear, adding occasionally a little Mucilage of Gum Arabic; then add the Starch and with a little water beat the whole into a mass, to be immediately divided into four hundred and eighty equal pills." *Ed.*

This preparation is very generally known by the name of *blue pill.* Made according to the directions of the U.S., London, and Dublin Pharmacopœias, it contains one grain of mercury in three of the mass; according to those of the Edinburgh, one grain in four. As the pill of our Pharmacopœia contains three grains of the mass, and that of the Edinburgh four grains, the two may be considered equivalent, each having one grain of the metal.

The condition of the mercury in this preparation is a point which has not yet been satisfactorily determined. There is no doubt that by far the greater portion is in the state of minute mechanical division, and not chemically altered. Some maintain that the whole of the metal is in this state, others, that a small portion is converted during the trituration into the black or protoxide of mercury, and that this is the ingredient upon which the activity of the pill depends. The oxidation is attributed partly to the influence of the air upon the surface of the metal, greatly extended by the separation of its particles; partly to the action of the substance used in the trituration. All agree that the efficacy of the preparation is proportionate to the extinction of the mercury, in other words, to the degree in which the metallic globules disappear. This extinction may be effected by trituration with various substances, and manna, syrup, honey, liquorice, mucilage, soap, and guaiac have been recommended, among others, for this purpose; but the confection of roses has been adopted in all the Pharmacopœias, as affording greater facilities and being less liable to objection than any other. The mercury is known to be completely extinguished, when, upon rubbing a small portion of the mass with the end of the finger upon a piece of paper or glass, no metallic globules appear. The powdered liquorice root is added in order to give the due degree of consistence to the mass. The Edinburgh College prefers starch for this purpose, as being less liable to become mouldy when the pills are kept. As the trituration requires to be continued a considerable length of time, and renders the process very laborious, it is customary in Great Britain to prepare the mass by machinery; and at Apothecaries' Hall, in London, the trituration is effected by the agency of steam. The machine there employed consists of "a circular iron trough for the reception of the materials, in which revolve four wooden cylinders, having also a motion on their axis." Much of the *mercurial pill* employed in this country is imported from England.

Medical Properties and Uses. These pills are among the mildest of the mercurial preparations, being less liable than most of the others to act upon the bowels, and exercising the peculiar influence of the remedy upon the system with less general irritation. They are much employed for producing the sialagogue and alterative action of mercury. For the former purpose, one pill may be given two or three times a day; and if the case is urgent, the dose may be increased. Even this preparation sometimes disturbs the bowels. It should then be given combined with a small proportion of opium, or in very minute doses, as half a grain or a grain of the mass repeated every hour or two through the day, so as to allow of its absorption before a sufficient quantity has been administered to act as an irritant. With a view to the alterative effect of the preparation upon the digestive organs, one pill may be given every night, or every other night, at bedtime, and followed in the morning, if the bowels should not be opened, by a small dose of some laxative medicine. The *blue mass* may frequently be administered with advantage, suspended in water by the intervention of thick mucilage; and it forms an excellent addition to the chalk mixture in diarrhœa, particularly that of children, when the biliary secretion is deficient, or otherwise deranged. W.

PILULÆ HYDRARGYRI CHLORIDI MITIS. *U.S.* *Pills of Mild Chloride of Mercury. Calomel Pills.*

"Take of Mild Chloride of Mercury [Calomel] *half an ounce;* Gum Arabic, in powder, *a drachm;* Syrup *a sufficient quantity.* Mix together the Chloride of Mercury and the Gum; then beat them with the Syrup so as to form a mass, to be divided into two hundred and forty pills." *U.S.*

This is a convenient form for administering calomel, of which one grain is contained in each pill. Soap, which was directed in the preparation of this pill in the first edition of the Pharmacopœia, is objectionable on account of its chemical incompatibility with calomel. Mucilage of gum Arabic alone does not form a sufficiently plastic mass; but gum and syrup united, as in the officinal formula, answer admirably well, forming a mass which is easily made into pills, and which readily yields to the solvent power of the stomach. W.

PILULÆ HYDRARGYRI SUBMURIATIS COMPOSITÆ. *Lond.* PILULÆ SUB-MURIATIS HYDRARGYRI COMPOSITÆ. *Ed.* PILULÆ CALOMELANOS COMPOSITÆ. *Dub.* *Compound Pills of Submuriate of Mercury. Compound Calomel Pills.*

"Take of Submuriate of Mercury [Calomel], Precipitated Sulphuret of Antimony, each, *two drachms;* Guaiac, in powder, *half an ounce;* Rectified Spirit *half a drachm.* Rub the Submuriate of Mercury with the Precipitated Sulphuret of Antimony, then with the Guaiac, and add the Spirit to give the proper consistence." *Lond.*

The *Edinburgh* and *Dublin Colleges* agree with the above proportions, but employ only half the quantity of materials, and, for the half drachm of rectified spirit, substitute—the former, a sufficient quantity of mucilage of gum Arabic, the latter, of molasses.

We prefer the name "Compound Calomel Pills" of the Dublin Pharmacopœia; as, though not scientific, it is not, like the others, chemically incorrect. The preparation was originally introduced to the notice of the profession of Dr. Plummer, who found it useful as an alterative, and upon whose authority it was at one time much employed under the name of *Plummer's Pills.* The combination is well adapted to the treatment of chronic rheumatism, and of scaly and other eruptive diseases of the skin, especially when accompanied with a syphilitic taint. Four grains of the mass contain about one grain of calomel. From three to six grains or more may be given morning and evening. W.

PILULÆ OPII. *U.S.* PILULÆ SAPONIS CUM OPIO. *Lond., Dub.* PILULÆ OPIATÆ. *Ed.* *Pills of Opium.*

"Take of Opium, in powder, *a drachm;* Soap, *twelve grains.* Beat them with water so as to form a mass, to be divided into sixty pills." *U.S.*

The *London* and *Dublin Colleges* direct *half an ounce* of opium and *two ounces* of hard soap, to be beat together till thoroughly incorporated. The *Edinburgh College* takes *one part* of opium, *seven parts* of extract of liquorice, and *two parts* of pimento; and having beat the opium and soap into a pulp, adds the pimento, previously powdered, and forms the whole into a mass.

The object of these preparations is different. The process of the U.S. Pharmacopœia is designed merely to furnish a convenient formula for putting opium into the pilular form, preferable to the mode sometimes practised of making the pills directly from the unpowdered mass of opium as found in commerce. The soap answers no other purpose than to give a due consistence, and is therefore in small proportion. Each pill contains a grain of opium.

The processes of the British Colleges are designed to afford a preparation, in which the opium, bearing a small proportion to the whole amount of ingredients, may be conveniently administered, by a division of the pilular mass, in small fractions of a grain. The additions in the Edinburgh preparation, while they dilute the opium, serve also to cover its taste. The name adopted by the London and Dublin Colleges is not appropriate, as opium, though in small proportion as to quantity, is yet the ingredient of greatest importance, and that which gives character to the pill. The London and Dublin preparation contains one grain of opium in five of the mass, that of Edinburgh one grain in ten. W.

PILULÆ QUINIÆ SULPHATIS. *U.S.* *Pills of Sulphate of Quinia.*

"Take of Sulphate of Quinia *an ounce;* Gum Arabic, in powder, *two drachms;* Syrup *a sufficient quantity.* Mix together the Sulphate of Quinia and the Gum; then beat them with the Syrup so as to form a mass, to be divided into four hundred and eighty pills." *U.S.*

Each pill contains a grain of sulphate of quinia, and twelve are equivalent to an ounce of good Peruvian bark. W.

PILULÆ QUINIÆ SULPHATIS IMPURI. *U. S.* *Pills of Impure Sulphate of Quinia.*

"Take of Impure Sulphate of Quinia *an ounce.* Beat it with water so as to form a mass, to be divided into two hundred and forty pills." *U.S.*

Each pill contains two grains of the impure sulphate, and may be considered as equivalent in medical power, to one grain of the pure sulphate of quinia. W.

PILULÆ RHEI COMPOSITÆ. *U.S., Ed.* *Compound Pills of Rhubarb.*

"Take of Rhubarb, in powder, *an ounce;* Aloes, in powder, *six drachms;* Myrrh, in powder, *half an ounce;* Oil of Peppermint *half a fluidrachm;* Syrup of Orange Peel *a sufficient quantity.* Beat the whole together so as to form a mass, to be divided into two hundred and forty pills." *U.S.*

The *Edinburgh College* employs the same ingredients, in the same proportions; but specifies the Socotrine aloes as the variety to be used, and does not divide the mass into pills.

This is a warm tonic laxative, useful in costiveness with debility of stomach. From two to four pills, or from ten to twenty grains of the mass, may be taken twice a day. W.

PILULÆ SCILLÆ COMPOSITÆ. *Lond., Dub.* PILULÆ SCILLITICÆ. *Ed.* *Compound Pills of Squill.*

"Take of Squill Root, fresh dried and powdered, *a drachm;* Ginger Root, in powder, Hard Soap, each, *three drachms;* Ammoniac, in powder, *two drachms.* Mix the powders together; then beat them with the Soap, and add as much Simple Syrup as may be sufficient to give the proper consistence." *Lond.*

The *Dublin College* employs the same ingredients, but adds the ammoniac without previously powdering it, and gives the due consistence by molasses, instead of simple syrup. The *Edinburgh College* takes of powdered squill *a scruple*, powdered ammoniac, cardamom, and liquorice, each, *a drachm;* and forms them into a mass with simple syrup.

This is a stimulant expectorant compound, depending for its virtues chiefly on the squill, and applicable to the treatment of chronic affections of the bronchial mucous membrane. From five to ten grains may be given three or four times a day. The preparation should be made when wanted for immediate use, as the squill which it contains is liable to be injured by keeping. W.

PILULÆ E STYRACE. *Dub.* *Storax Pills.*

"Take of Purified Storax *three drachms;* Turkey Opium, Saffron, each, *a drachm.* Beat them together till they are thoroughly mixed." *Dub.*

In these pills the storax and saffron are added merely to conceal the taste and smell of the opium, as the name of the pills is intended to conceal their real character. This contrivance is esteemed necessary; as some individuals have a prejudice against the use of opium, which reason cannot overcome. Five grains of the mass contain a grain of opium. W.

PILULÆ SUBCARBONATIS SODÆ. *Ed.* *Pills of Subcarbonate of Soda.*

Take of Dried Sub-Carbonate of Soda [carbonate of soda] *four parts;* Hard Soap *three parts.* Beat them into a mass with Simple Syrup." *Ed.*

The carbonate of soda being efflorescent, should always be deprived of its water of crystallization before being made into pills. This form of administering it may sometimes be advantageously resorted to, when the palate or stomach rejects the solution. W.

PILULÆ SULPHATIS FERRI COMPOSITÆ. *Ed.* *Compound Pills of Sulphate of Iron.*

"Take of Sulphate of Iron, in powder *an ounce;* Extract of Chamomile *an ounce and a half;* Oil of Peppermint *a drachm.* Beat them into a mass with Simple Syrup." *Ed.*

This is a good tonic pill, applicable to most complaints in which chalybeates are administered. About two grains of the sulphate are contained in a pill of five grains. W.

PLUMBUM.

Preparations of Lead.

LIQUOR PLUMBI SUBACETATIS. *U.S., Lond.* PLUMBI SUBACETATIS LIQUOR. *Dub.* *Solution of Subacetate of Lead.*

"Take of Acetate of Lead, Semivitrified Oxide of Lead, each, *eight ounces;* Distilled Water *two pints.* Mix in a glass vessel, and boil for twenty minutes; then filter through paper." *U. S.*

"Take of Semivitrified Oxide of Lead *two pounds;* Diluted Acetic Acid [Distilled Vinegar] *a gallon.* Mix and boil down to six pints, constantly stirring; then set the liquor by that the dregs may subside, and filter." *Lond.*

"Take of Semivitrified Oxide of Lead *one part;* Distilled Vinegar *twelve parts.* Boil together in a glass vessel until eleven parts of the fluid remain, then let the liquor rest, and when the impurities have subsided, let it be filtered." *Dub.*

Crystallized acetate of lead consists of one equivalent of acetic acid 51.48, one of protoxide of lead 111.6, and three of water 27=190.08. Litharge as usually found in the shops is an impure protoxide of lead. When a solution of the former is boiled with the latter, a large quantity of the protoxide is dissolved, and a subacetate of lead is formed which remains in solution. The precise composition of the subacetate varies with the proportions of acetate of lead and of litharge employed. When the quantity of the latter exceeds that of the former by one-half or more, the acetic acid of the acetate unites, according to the highest chemical authorities, with two additional equivalents of protoxide, forming a trisacetate; when the two substances are mixed in proportions corresponding to their equivalent numbers, that is, in the proportion of 190.08 of salt to 111.6 of oxide, or 10 to 6 nearly, only one additional equivalent of protoxide unites with the acid, and a diacetate of lead, according to Dr. Thomson, is produced. As the quantity of litharge directed in the U.S. Pharmacopœia, is intermediate between these proportions, it is probable that the solution which results, contains both the diacetate and trisacetate. The litharge should be employed in the state of very fine powder, and, according to Thenard, should be previously calcined in order to decompose the carbonate of lead, which it always contains in greater or less proportion, and which is not dissolved by the solution of the acetate. We have found by experiment, that the solution is diminished about four fluidounces by the boiling, and that when prepared it has the sp. gr. 1.285 at 60°.

The processes of the London and Dublin Colleges also result in the production of a subacetate of lead, one equivalent of the acetic acid of the vinegar combining directly with two equivalents of the protoxide of the litharge, to form a diacetate. That a trisacetate is not produced may be inferred from the fact ascertained by Dr. Barker, that distilled vinegar dissolves only about one-twelfth of its weight of the litharge, which is not nearly sufficient to afford three equivalents of protoxide to one of the acid. Besides, according to Phillips and Duncan, the resulting salt has been proved by the analysis of Dr. Bostock to be composed of one equivalent of acid and two of base. The quantity of litharge directed by the London College is much larger than necessary, not one-half of it being dissolved by the distilled vinegar. The strength of the solution necessarily varies with the strength of the vinegar, and this is an objection against the British processes, to which ours is not equally liable. We are told by Phillips, that the sp. gr. of the solution prepared with distilled vinegar of 1.007 is 1.220, with that of 1.009 is 1.309; while Dr. Barker states the specific gravity of the saturated solution prepared by himself with distilled vinegar, to be only 1.118 at 68°. Common vinegar yields a dark brown solution, and is therefore not employed.

Properties. The solution of subacetate of lead of the U.S. Pharmacopœia is colourless, that of the British Colleges has a pale greenish-straw colour, arising from impurities in the distilled vinegar. Its taste is sweetish and astringent. When concentrated by evaporation, it deposites on cooling crystalline plates, which, according to Dr. Barker, are flat rhomboidal prisms with dihedral summits. It has an alkaline reaction, tinging the syrup of violets green, and reddening turmeric paper. One of its most striking properties is the extreme facility with which it is decomposed. Carbonic acid throws down a white precipitate of carbonate of lead, and this happens by mere exposure to the air, or by mixture even with distilled water, if this has had an opportunity of absorbing carbonic acid from the atmosphere. It affords precipitates also with the alkalies, alkaline earths, and their carbonates, with sulphuric and muriatic acids free or combined, with hydrosulphuric acid and the hydrosulphates, and, according to Thenard, with solutions of all the neutral salts. Solutions of gum, tannin, most vegetable colouring principles, and many animal substances, produce with it precipitates consisting of the substance added and oxide of lead. It should be kept in well stopped bottles.

Medical Properties and Uses. This solution is astringent and sedative; but is employed only as an external application. It is highly useful in inflammation arising from sprains, bruises, burns, blisters, &c., to which it is applied by means of linen cloths, which should be removed as fast as they become dry. It always, however, requires to be diluted. From four fluidrachms to a fluidounce, added to a pint of distilled water, forms a solution sufficiently strong in ordinary cases of external inflammation. When applied to the skin denuded of the cuticle, the solution should be still weaker, as constitutional effects might result from the absorption of the lead. Paralysis is said to have been produced by its local action; but we have not witnessed such an effect. The solution has the common name of *Goulard's extract*, derived from a surgeon of Montpellier by whom it was introduced into notice. W.

LIQUOR PLUMBI SUBACETATIS DILUTUS. *U.S., Lond.* PLUMBI SUBACETATIS LIQUOR COMPOSITUS. *Dub. Diluted Solution of Subacetate of Lead. Lead-water.*

"Take of Solution of Subacetate of Lead *a fluidrachm;* Distilled Water *a pint.* Mix them." *U.S.*

The *London* and *Dublin* processes differ from the above only in adding a fluidrachm of proof spirit to the other ingredients.

This preparation is convenient, as in consequence of the subsidence of the carbonate of lead usually formed on the dilution of the strong solution, it enables the apothecary to furnish clear lead-water when it is called for. The strength, however, is hardly sufficient for the ordinary purposes to which lead-water is applied. The Paris Codex directs two drachms of the strong solution to a pound of distilled water, and an ounce of alcohol of 22° Baumé; and thus forms the *vegeto-mineral water* of Goulard. The minute proportion of proof spirit added by the British Colleges can have no sensible effect. W.

POTASSA.

Preparations of Potassa.

LIQUOR POTASSÆ. *U. S., Lond.* AQUA POTASSÆ. *Ed.* POTASSÆ CAUSTICÆ AQUA. *Dub. Solution of Potassa.*

"Take of Carbonate of Potassa *a pound;* Lime, fresh burnt, *half a pound;* Boiling Distilled Water *a gallon.* Dissolve the Carbonate of Potassa in two pints of the Water, and add the remainder to the Lime. Mix the hot liquors; then set the mixture aside in a covered vessel, and when cold strain it through a cotton cloth. If effervescence be produced upon the addition of a diluted acid, more lime should be added, and the liquor again strained. A pint of this solution should weigh sixteen ounces." *U. S., Lond.*

"Take of recently burnt Lime *eight ounces;* Sub-Carbonate of Potassa *six ounces:* Boiling Water *twenty-eight ounces.* Pour upon the Lime, in an iron or earthen vessel, twenty ounces of the Water. After the ebullition has ceased, immediately add the Salt, dissolved in eight ounces of the Water; and having thoroughly mixed the materials, cover the vessel until they cool. When the mixture has cooled, stir it well, and pour it into a glass funnel, the throat of which is obstructed with a piece of clean linen. Cover the upper orifice of the funnel and insert its tube into another glass vessel, so that the Water of Potassa may gradually drop, through the linen, into the lower vessel. As soon as it ceases to drop, pour into the funnel some ounces of water, but cautiously, so that it may swim above the matter in the funnel. The Water of Potassa will again begin to drop; and the affusion of water is to be repeated in the same manner, until three pounds have dropped, which will happen in the space of two or three days. Then mix the superior and inferior parts of the liquor together by agitation, and keep it in a well stopped bottle." *Ed.*

Take of Carbonate of Potassa from Pearlash, fresh-burnt Lime, each, *two parts;* Water *fifteen parts.* Sprinkle one part of the Water, previously heated, on the Lime, placed in an earthen vessel; and when it is slaked, mix the salt with it immediately, and then add the remainder of the Water. When the mixture has cooled, put it into a well stopped bottle, and shaking it frequently, keep it for three days. When the Carbonate of Lime has subsided, decant the supernatant liquor, and keep it in green glass bottles, well stopped. The specific gravity of this solution is 1.080." *Dub.*

The object of these processes is to separate carbonic acid from the carbonate of potassa, so as to obtain the alkali in a caustic state. This is effected by hydrate of lime; and the chemical changes which take place are most intelligbly explained by supposing the occurrence of a double decomposition. The lime of the hydrate of lime, by its superior affinity, combines with the carbonic acid, and precipitates as carbonate of lime; while the water of the hydrate unites with the potassa, and remains in solution as the hydrate of potassa. The proportion indicated by theory for this decomposition would be 69.27 of the carbonate to 28.5 of lime, or one equiv. of each; but in practice it is found necessary to use an excess of lime. In the U.S. and London process, the alkaline salt is treated with half its weight of lime, in the Dublin formula with its own weight; and in the Edinburgh, with one and a third times its weight; proportions, even the lowest of which exceeds the theoretical quantity. From the experiments of Dr. Barker it appears, that the carbonate of potassa, to be fully decomposed, requires at least five-sixths of its weight of lime, with the aid of a sufficient quantity of water to promote the chemical reaction. Hence it may be inferred, that the medium proportion of lime ordered by the Dublin College is the most eligible in practice. The Edinburgh proportion is certainly excessive; and any defect in the preparation, arising out of the deficient action of the lime in the U.S. and London formula, is remedied by the direction to add more lime, in case the solution, as first obtained, should effervesce with acids. The disadvantages of using an excess of lime are the necessity of employing larger vessels, on account of the bulk of the materials, and the loss of a portion of alkaline solution which is retained by the spongy residuum. The proportion of water employed has a decided influence on the result. If the water be deficient in quantity, the decomposing power of the lime, on account of its sparing solubility, will be lessened; and more of it will be required to complete the decomposition of the carbonate, than if the solutions had been more dilute. The quantity ordered in the U.S. and London formula is ample, being more than ten times the weight of the alkaline salt employed, but is deficient in the Edinburgh process. The plan of agitation and decantation, pursued by the Dublin College, is better than straining or filtration; as these latter operations give rise to a longer exposure to the air, and consequently increase the liability of the solution to absorb carbonic acid. Filtration, however, may be performed, so as to prevent the contact of any air, except that contained in the filtering apparatus itself, by pursuing the method described at page 692. The direction of the Dublin College to keep the solution of potassa in green glass bottles is judicious; as white glass is slightly acted on.

As the solution of potassa is frequently made by the operative chemist in considerable quantities, the following details as to the best mode, according to Berzelius, of conducting the process, may not be without their use. Dissolve one part of carbonate of potassa in from seven to twelve parts of water, in a bright iron vessel, and decant the solution after it has become clear by standing. Boil the solution in an iron vessel, and while it is boiling, add, at intervals small quantities of slaked lime reduced to a thin paste with water; allowing the solution to boil a few minutes after each addition. One and a half parts of pure lime will be more than sufficient to decompose one part of the carbonate. When about half the hydrate of lime has been added, take out about a teaspoonful of the boiling solution, and after dilution, and filtration through paper, test it by adding it to some nitric acid, or by mixing it with an equal bulk of lime-water. If the solution has not been completely freed from carbonic acid, the first reagent will cause an effervescence, and the second a milky appearance; in either of which events the addition of the lime must be continued as before, until the above mentioned tests give negative indications. In performing this operation, two advantages are gained by keeping the solution constantly boiling. One is that the carbonate of lime formed is in this way rendered granular and heavy, and more disposed to subside; and the other, that it prevents the precipitated carbonate from coalescing into a mass at the bottom of the vessel, an occurrence which causes the ebullition, when subsequently renewed, to take place imperfectly and by jerks.

Properties, &c. Solution of potassa is a limpid, colourless liquid, of an oleaginous appearance, without smell, and having a very acrid and caustic taste. It acts rapidly on animal and vegetable substances, and when rubbed between the fingers produces a soapy feel, in consequence of a partial solution of the cuticle. It dissolves gum, resins, and extractive matter, and, by union with oily and fatty bodies, forms soap. The officinal solution is never perfectly pure, but contains either some undecomposed carbonate, or free lime, in addition to minute portions of sulphate and muriate of potassa, silica, and alumina, impurities usually present in the carbonate of potassa obtained from pearlash, which is used in its preparation. Undecomposed carbonate may be detected in the manner explained in the preceding paragraph, and free lime, by the production of a milky appearance on the addition of a few drops of carbonate of potassa, which serves to precipitate the lime as a carbonate. It is incompatible with acids, acidulous salts, and all metallic and earthy preparations held in solution by an acid; as also with all ammoniacal salts, and with calomel and corrosive sublimate. This solution, as it is intended for medicinal employment, should be of uniform strength. The weight which a pint of it is directed to have in the U.S. and London Pharmacopœias, indicates a sp. gr. of 1.056. The Dublin solution is ordered to be of the sp. gr. 1.08; while the density of the Edinburgh preparation is not designated. These solutions are quite dilute; for, according to a table given by Dalton, a solution having the sp. gr. 1.06, contains only 4.7 per cent. of the alkali. On account of its strong attraction for carbonic acid, the solution of potassa should be carefully preserved from the contact of the air. B.

Medical Properties and Uses. Solution of potassa is antacid, diuretic, and antilithic. It has been much employed in calculous complaints, under the impression that it has the property of dissolving urinary concretions in the kidneys and bladder; but experience has proved that the stone once formed cannot be removed by remedies internally administered, and the most that the alkaline medicines can effect, is to correct that disposition to the superabundant secretion of uric acid, or the insoluble urates, upon which gravel and stone often depend. For this purpose, however, the carbonated alkalies are preferable to caustic potassa, as they are less apt to irritate the stomach, and to produce injurious effects when long continued. It has been proposed to dissolve calculi by injecting immediately into the bladder the solution of potassa in a tepid state, and so much diluted that it can be held in the mouth; but this mode of employing it has not been found to answer in practice. This solution has also been highly recommended in lepra, psoriasis, and other cutaneous affections; and is said to have proved peculiarly useful in scrofula; but in all these cases it probably acts simply by its antacid property, and is not superior to the carbonate of potassa or of soda. Externally it has been used in a diluted state as a stimulant lotion in rachitis and arthritic swellings, and concentrated, as an escharotic in the bite of rabid or venomous animals. The dose is from ten to thirty minims, repeated two or three times a day, and gradually increased in cutaneous affections to one or two fluidrachms; but the remedy should not be too long continued, as it is apt to debilitate the stomach. It may be given in sweetened water or some mucilaginous fluid. Veal broth and table beer have been recommended as vehicles; but the fat usually present in the former, would be liable to convert it into soap, and the acid in the latter would neutralize it. In dyspeptic cases it may be associated with the simple bitters.

It is employed pharmaceutically in the preparation of the Precipitated Sulphuret of Antimony, and by the Dublin College in forming the Black Oxide of Mercury.

Off. Prep. Potassa, *U.S.*, *Lond.*, *Ed.*, *Dub.;* Potassa cum Calce, *Lond.*, *Ed.*, *Dub.;* Potassii Iodidum, *U.S.* W.

POTASSA. *U.S. Ed.* POTASSA FUSA. *Lond.* POTASSA CAUSTICA. *Dub.* *Potassa.* *Caustic Potassa.*

"Take of Solution of Potassa *a gallon.* Evaporate the water in a clean iron vessel, over the fire, till ebullition ceases, and the Potassa melts. Pour this into suitable moulds." *U.S.*

The *London* formula is the same as the above, except that it directs that the melted potassa should be "poured out upon an iron plate into pieces of a proper form."

"Take of Solution of Potassa *any quantity.* Evaporate it in a very clean covered iron vessel, until, on the ebullition ceasing, the saline matter flows gently like oil, which happens before the vessel becomes red hot. Then pour it out on a clean iron plate, and before it hardens, cut it into small pieces, which are immediately to be put into a well stopped bottle." *Ed.*

"Take of Water of Caustic Potassa *any quantity.* Evaporate it over the fire in a perfectly clean silver or iron vessel, until the ebullition shall have ceased, and the saline matter, on increasing the heat, shall remain perfectly at rest in the vessel. Pour out the liquified Potassa on a silver or iron plate, and, whilst concreting, cut it into pieces of a proper size, which are immediately to be introduced into a well stopped bottle. The operator should carefully avoid the drops which are ejected from the vessel during the evaporation." *Dub.*

The concrete alkali obtained by these processes, is a hydrate of potassa, sufficiently pure for medical purposes. The solution of the alkali freed from carbonic acid having been obtained by another formula, (see *Liquor Potassæ,*) the formation of the present preparation requires merely the evaporation of this solution, until the whole of its uncombined water is driven off. The evaporation is required to be performed in metallic vessels, as those of glass or earthenware are acted on by the alkali; and it should be completed as quickly as possible to abridge the period during which the solution would be liable to absorb carbonic acid from the atmosphere. When poured out on a metallic plate, the cake just as it concretes may be marked with a knife in the directions in which it is to be divided; and when cold, it readily breaks in those directions. A better plan, however, is to run the fused alkali, as directed in the U.S. formula, into suitable moulds. These should be made of iron and have a cylindrical shape, which is the most convenient form of the alkali for the use of the surgeon. Green glass bottles with ground stoppers are the best adapted for preserving this preparation; as white flint glass is slightly acted on.

Properties, &c. In its officinal impure form, potassa has usually a dingy gray or green colour, occasionally a bluish tint, and the peculiar odour of slaking lime. It is extremely caustic and very deliquescent, and dissolves in less than its weight of water. It is also readily soluble in alcohol. When exposed to a low red heat it melts, and at bright redness is volatilized. On account of its deliquescent property, and its strong attraction for carbonic acid, it requires to be kept in very accurately stopped bottles. In the state here described, the alkali always contains combined water as a part of its composition. It contains also several impurities, such as sulphate of potassa, chloride and peroxide of potassium, peroxide of iron, lime, and a portion of the alkali itself still in a carbonated state. It may be freed from these impurities by digesting it in alcohol, which will take up only the pure hydrated alkali, evaporating the alcoholic solution to dryness, and fusing the dry mass obtained. *Pure hydrate of potassa*, when thus procured, is usually called *alcoholic potassa.* It is generally in the form of flat white pieces, which are dry, hard, and brittle, and extremely caustic. Its other properties are similar to those of the impure hydrate above described. It may be discriminated from the other fixed alkalies (soda and lithia) by affording, when in solution, a crystalline precipitate (cream of tartar) with an excess of tartaric acid, and a yellow one with muriate of platinum. The officinal potassa, apart from impurities, consists of one equiv. of dry potassa 47.15 and one of water 9=56.15. Dry potassa is formed of one equiv. of potassium 39.15 and one of oxygen 8=47.15. (See *Potassium.*) B.

Medical Properties and Uses. This is the old *causticum commune acerrimum*, or strongest common caustic. It is a very powerful escharotic, quickly destroying the life of the part with which it comes in contact, and extending its action to a considerable depth beneath the surface. In this latter respect, it differs from the nitrate of silver or lunar caustic, to which it is, therefore, preferred for the purposes of forming issues and opening abscesses. It is sometimes used for removing stricture of the urethra; but in consequence of its tendency to spread, it may, unless carefully applied, produce such a destruction of the lining membrane, as to open a passage for the urine into the cellular membrane, and thus involve the patient in danger. The most convenient mode of employing the caustic for the formation of an issue, is to apply to the skin a piece of linen spread with adhesive plaster, having a circular opening in its centre corresponding to the intended size of the issue, and then to rub upon the skin within the opening a piece of the caustic previously moistened at one end. The application is to be continued till the life of the part is destroyed, when the caustic should be carefully washed off by a wet sponge or wet tow, or neutralized by vinegar. The preparation is also employed for forming solutions of potassa of definite strength, whether for medicinal or pharmaceutic use. A solution of one drachm and a half of caustic potassa in two fluidounces of distilled water, is highly recommended by Dr. Hartshorne, as an application to the spine in tetanus. It may be applied by means of a sponge attached to the end of a stick, which should be drawn quickly along the back from the nape of the neck to the sacrum. It produces a very powerful rubefacient effect.

The U.S. Pharmacopœia employs caustic potassa in the preparation of the black oxide of mercury. W.

POTASSA CUM CALCE. *Lond., Ed.* POTASSA CAUSTICA CUM CALCE. *Dub.* *Potassa with Lime.*

"Take of Solution of Potassa *three pints;* fresh-burnt Lime *a pound.* Boil down the Solution of Potassa to a pint; then add the Lime, previously slaked with water, and mix them thoroughly." *Lond.*

"Take of Water of Potassa *any quantity.* Evaporate it to one-third in a covered iron vessel; then mix with it as much newly slaked and powdered lime as will bring it to the consistence of a solid paste, which is to be preserved in a well stopped bottle." *Ed.*

"Evaporate Water of Caustic Potassa to one-fourth; then add as much fresh-burnt Lime, in powder, as will form a mass of the proper consistence, which is to be preserved in a well stopped bottle." *Dub.*

In making this preparation, the alkaline solution is so far concentrated, as that, upon the addition of the lime, and the cooling of the mixture, the whole becomes a granular mass, consisting of the mixed hydrates of potassa and lime. Potassa with lime, like the officinal potassa, is only used as a caustic; but it is more manageable than the latter preparation, owing to the presence of the lime, which renders it milder and slower in its operation, and also less deliquescent, and, therefore, less liable to spread beyond the part intended to be affected. This preparation was formerly called *causticum commune mitius*, or milder common caustic. B.

POTASSÆ CARBONAS. *U.S.* POTASSÆ SUBCARBONAS. *Lond.* SUB-CARBONAS POTASSÆ. *Ed.* POTASSÆ CARBONAS E LIXIVO CINERE. *Dub.* *Carbonate of Potassa. Subcarbonate of Potassa. Carbonate of Potassa from Pearlash.*

"Take of Impure Carbonate of Potassa [pearlash], in powder, *three pounds;* Water *two pints and a half* [boiling Water three pints and a half, *Lond.*]. Dissolve the Impure Carbonate of Potassa in the Water, and filter the solution; then pour it into a clean iron vessel, and evaporate the Water over a gentle fire till the solution thickens; lastly, remove it from the fire, and stir it constantly with an iron spatula, till the salt granulates." *U.S., Lond.*

"Subcarbonate [Carbonate, *U.S.*] of Potassa may be obtained in a similar manner from Tartar, previously burnt till it becomes of an ash colour." *Note to the Lond. formula.*

"Expose Impure Sub-Carbonate of Potassa [pearlash], in a crucible, to a red heat; then triturate it well with an equal weight of water. Pour the solution, after the impurities have subsided, into a very clean iron pot, and boil it to dryness; stirring the salt assiduously towards the end of the process, to prevent it from adhering to the vessel." *Ed.*

"Take of Pearlash, in coarse powder, cold Water, each, *one part.* Mix them by trituration, and macerate for a week, in a wide vessel, with occasional agitation. Then filter the lixivium, and evaporate it to dryness in a very clean silver or iron vessel. Towards the end of the evaporation, stir the saline mass constantly with an iron spatula. In this manner, having reduced it to a coarse powder, preserve it in close vessels. If the Pearlash is not sufficiently pure, roast it in a crucible until it becomes white, before dissolving it in the Water." *Dub.*

The object of the above processes is to purify the impure carbonate of potassa, or pearlash. This generally contains certain insoluble impurities, as well as small portions of sulphate and silicate of potassa, and chloride of potassium, as explained under another head. (See *Potassæ Carbonas Impurus.*) By dissolving it in a due proportion of water, and filtering the solution, the insoluble impurities are got rid of, as well as the greater part of the foreign salts, which being much less soluble than the carbonate of potassa, are excluded by the superior affinity of this salt for the water. The proper way of conducting the purification is to mix the impure carbonate with an equal weight of *cold* water, and to allow the mixture to stand for a day or two, stirring it frequently to promote the action of the water. The clear liquor, obtained by decantation or filtration, is then evaporated to dryness. The U.S., Edinburgh, and Dublin processes are conducted very much in this way; cold water being employed, and equal weights of alkali and water being used in the Edinburgh and Dublin formulæ, and nearly equal weights in the process of the U.S. Pharmacopœia. The London College has committed an error in ordering a larger proportion of water, and in directing it to be boiling. The prolonged contact of the water with the salt, and the occasional stirring of the mixture ordered by the Dublin College, are useful directions. In no case should the undissolved residue be washed with a fresh portion of water, as, by such a proceeding, the foreign salts, which it is the object of the process to separate, would be dissolved. Iron or silver vessels are directed, because these metals are not acted on by the alkali, while glass is attacked by it. Mr. Phillips says copper vessels are generally preferred, and may be used without inconvenience. In granulating the salt by stirring, it is better to keep it on the fire until the process is finished, than to remove it at the moment it thickens.

According to Berzelius, a more productive process for purifying pearlash, though the salt is not so pure as when obtained by the process just described, is to dissolve the impure salt in more than its weight of water, to evaporate the solution till it has the density of 1.52, and then to put it in a cool place, that the foreign salts, principally muriate and sulphate of potassa, may crystallize. The solution is then decanted, and evaporated to dryness.

Properties, &c. Carbonate of potassa, as found in the shops, is in the form of a coarse white granular powder, having a nauseous, alkaline taste, and acting as an alkali on vegetable colours. It is very soluble in water, dissolving in its weight of that liquid; but is insoluble in alcohol. It is extremely deliquescent, and hence, a porton of it exposed to the air for some time, attracts so much water as completely to dissolve into an oily liquid, called by the older chemists, *oleum tartari per deliquium.* On account of this property, carbonate of potassa should be kept in bottles with accurately ground stoppers. If exposed, in its usual state, to a red heat, it retains its carbonic acid, but loses from ten to fifteen per cent. of water, which appears to be hygrometric, and not chemically combined. It should be completely soluble in water, and any insoluble residue is indicative of impurity. The usual impurities are some earthy matter, and about three per cent. of the muriate and sulphate of potassa, with a little silica in the state, probably, of silicated potassa; but the presence of these substances in so small an amount does not interfere with its medical efficacy. It is incompatible with acids and acidulous salts, muriate and acetate of ammonia, lime-water and muriate of lime, sulphate of magnesia, alum, tartar emetic, nitrate of silver, ammoniated copper and ammoniated iron, sulphate of iron and tincture of muriate of iron, calomel and corrosive sublimate, acetate and subacetate of lead, and sulphate of zinc. It is not decomposed by the tartrate of iron and potassa, and, therefore, may be associated with it in prescriptions.

Composition. Carbonate of potassa, as obtained by evaporation to dryness, is an anhydrous salt, consisting of one equiv. of carbonic acid 22.12, and, one of potassa 47.15=69.27. As it is neutral in composition, the name by which it is designated in the U.S. and Dublin Pharmacopœias is strictly correct. The possession of an alkaline reaction cannot justify its being called a *sub*carbonate; since, on the same ground, the bicarbonate would be a subcarbonate, as it possesses an alkaline reaction also. B.

Medical Properties and Uses. Purified pearlash is the form of carbonate of potassa usually employed in this country, where it is frequently, though incorrectly, called *salt of tartar*, the latter name being strictly applicable to the purer carbonate, obtained by decomposing cream of tartar. It is occasionally used as an antacid in dyspepsia, as a diuretic in dropsy, and as an antilithic in gravel attended with red deposites from the urine; but the purpose to which it is most commonly applied is the formation of the *neutral mixture* and *effervescing draught*. (See page 395.) It is worthy of observation, that its solution, on exposure to the air, or on the addition of an acid, deposites flocculi consisting of hydrate of silica, resulting from the decomposition of the silicated potassa, which is always present as an impurity. The spontaneous deposition of silica is owing to the absorption of carbonic acid. Carbonate of potassa is also used with much advantage in some cases of jaundice, in which it probably operates by entering the circulation and directly exciting the hepatic function. The dose is from ten to thirty grains, given in some aromatic water sweetened with sugar.

POTASSÆ CARBONAS PURISSIMUS. *U.S.* SUB-CARBONAS POTASSÆ PURISSIMUS. *Ed.* POTASSÆ CARBONAS E TARTARI CRYSTALLIS. *Dub.* *Purest Carbonate of Potassa. Carbonate of Potassa from Crystals of Tartar. Salt of Tartar.*

"Take of Supertartrate of Potassa [cream of tartar] *two pounds;* Nitrate of Potassa *a pound.* Rub them separately into powder; then mix, and throw them into a brass vessel heated nearly to redness, that they may undergo combustion. From the residue prepare the Purest Carbonate of Potassa, in the manner directed for the Carbonate." *U. S.*

"Take of Impure Super-Tartrate of Potassa [crude tartar] *any quantity.* Wrap it up in moist bibulous paper, or put it into a crucible, and having surrounded it with live coals, burn it into a black mass. Reduce this to powder, and expose it, in an open crucible, to the action of a moderate fire, until it becomes white, or at least of an ash colour; care being taken that it do not melt. Then dissolve it in warm water, strain the solution through a linen cloth, and evaporate it in a clean iron vessel, diligently stirring it towards the end of the process with an iron spoon to prevent the matter from adhering to the bottom of the vessel. A very white salt will remain, which is to be left a little longer on the fire, until the bottom of the vessel becomes nearly red. Lastly, when the salt has grown cold, keep it in well stopped glass vessels." *Ed.*

"Take of Crystals of Tartar *any quantity.* Heat them to redness in a silver crucible, loosely covered, until they cease to emit vapours. Reduce the residue to a coarse powder, and roast it for two hours in the same crucible, without a cover, stirring it frequently; then boil it with twice its weight of water for a quarter of an hour, and after the requisite subsidence, pour off the clear liquor. Repeat this three times. Filter the mixed solutions, and evaporate them in a silver vessel. Granulate the residual salt by frequently stirring it while it is becoming dry, and then heat it to dull redness. Before it is perfectly cold, take it out of the vessel, and preserve it in well stopped bottles." *Dub.*

The product of the above processes is a carbonate of potassa, purer than that described under the preceding head. In the U.S. formula the salts employed undergo decomposition by the deflagration to which they are subjected; the tartaric and nitric acids are totally decomposed, and sufficient carbonic acid is formed, as one of the products of their decomposition, to saturate the common base of the two salts, and thus to generate carbonate of potassa. This, however, is mixed with a portion of redundant charcoal, which gives the product a black colour; and from its colour and use in this state it was formerly called *black flux*. It is freed from carbonaceous matter by being treated in the manner directed for purifying the carbonate obtained from pearlash.

The Edinburgh and Dublin Colleges form this carbonate by incinerating the supertartrate without nitre. The tartaric acid, which consists of hydrogen, carbon, and oxygen, is decomposed, and gives rise, among other products, to carbonic acid, which combines with the potassa. The matter, after ignition, contains, besides carbonate of potassa, certain impurities derived from those pre-existing in the supertartrate. These are carbonate of lime, arising from the decomposition of tartrate of lime, alumina, silica, and minute portions of the oxides of iron and manganese; and being all insoluble in water, are left behind when the mass is acted on by that liquid, the alkaline carbonate alone being taken up. The insoluble matter is greater in the incinerated mass of the Edinburgh process than in that of the Dublin; as crude tartar is employed in the former, while crystals of tartar are used in the latter.

The London College does not recognise a separate preparation under the name of "purest carbonate of potassa," but gives the formula for obtaining it as an additional method for preparing their "subcarbonate of potassa." (See *preceding article.*)

Properties, &c. Carbonate of potassa obtained from tartar differs from the same salt procured from pearlash, only in containing fewer impurities. It was formerly called *salt of tartar*, in allusion to its source; but at present, the same name is familiarly applied to any carbonate of potassa of good quality, without reference to its mode of preparation. It may, indeed, be very much doubted whether the real salt of tartar is often kept in our shops; the carbonate as purified from pearlash being generally substituted for it, and answering every medicinal purpose that could be expected from the use of the purer salt.

Medical Properties and Uses. These are precisely the same with those of the carbonate of potassa described in the preceding article.

Off. Prep. Aqua Super-Carbonatis Potassæ, *Ed.;* Carbonas [Bicarbonas] Potassæ, *Ed.;* Liquor Potassæ Arsenitis, *U.S.*, *Lond.*, *Ed.*, *Dub.;* Potassæ Acetas, *Dub.;* Potassæ Carbonatis Aqua, *Dub.* B.

LIQUOR POTASSÆ CARBONATIS. *U.S.* LIQUOR POTASSÆ SUBCARBONATIS. *Lond.* POTASSÆ CARBONATIS AQUA. *Dub.* *Solution of Carbonate of Potassa. Solution of Subcarbonate of Potassa.*

"Take of Carbonate of Potassa *a pound;* Distilled Water *twelve fluidounces.* Dissolve the Carbonate of Potassa in the Water, and filter the solution through paper." *U.S.*, *Lond.*

"Take of Carbonate of Potassa from Crystals of Tartar *one part;* Distilled Water *two parts.* Dissolve and filter. The specific gravity of this solution is 1.320." *Dub.*

This is simply a solution of carbonate of potassa in water, and furnishes a convenient form for the administration of this salt. The U.S. and London process gives a liquid of the sp. gr. 1.446. The Dublin process differs in using the purer form of the carbonate, and in furnishing a solution considerably weaker. This solution should be colourless and inodorous, and possess the general alkaline qualities of the salt from which it is formed. The dose of the U.S. solution is from ten minims to a fluidrachm, sufficiently diluted with water or some bland liquid.

B.

POTASSÆ BICARBONAS. *U.S.*, *Dub.* POTASSÆ CARBONAS. *Lond.* CARBONAS POTASSÆ. *Ed.* *Bicarbonate of Potassa.*

"Take of Solution of Carbonate of Potassa [Solution of Subcarbonate of Potassa, *Lond.*] *a gallon.* Pass Carbonic Acid through the Solution, in a suitable vessel, till it is fully saturated; then filter, and evaporate the filtered liquor, that crystals may form, taking care that the heat does not exceed one hundred and twenty degrees. Pour off the liquor, and dry the crystals upon bibulous paper. Carbonic Acid is obtained from Hard Carbonate of Lime [White Marble, *Lond.*], by the addition of Dilute Sulphuric Acid." *U.S.*, *Lond.*

"Take of Purest Sub-Carbonate of Potassa [salt of tartar] *two parts;* Water *three parts.* Dissolve the salt in the Water, and, in a suitable apparatus, pass through it a stream of Carbonic Acid Gas. Filter the solution when it ceases to absorb acid, and afterwards evaporate it with a heat not exceeding one hundred and eighty degrees, so that crystals may form. Carbonic Acid is easily obtained from equal weights of Carbonate of Lime in powder, and Sulphuric Acid diluted with much water." *Ed.*

"Take of Carbonate of Potassa from Pearlash *one part;* Distilled Water *two parts.* Dissolve, and expose the solution, in a suitable apparatus, to a current of Carbonic Acid Gas, evolved from white marble by the action of dilute Muriatic Acid, until the liquid becomes turbid. Then filter it, and again expose it to the stream of Carbonic Acid Gas, until the alkali is saturated. Lastly, put the solution in a cool place, that it may form crystals, which are to be dried without heat, and kept in a well stopped bottle." *Dub.*

In these processes, the *regular* carbonate of potassa, consisting of one equiv. of acid and one of base, erroneously called a subcarbonate by the London and Edinburgh Colleges, is combined with an additional equivalent of carbonic acid. The combination is effected by passing a stream of this acid through a solution of the carbonate, so long as it is absorbed. The solution employed is directed of different strengths. In the U.S. and London formula, the officinal solution of the carbonate being ordered, the salt and water exist in nearly equal parts; in the Edinburgh formula, they are to each other as 2 to 3, and in the Dublin, as 1 to 2. The Edinburgh differs from the other Pharmacopœias in using the purest form of the officinal carbonate for forming the solution. The saturation is best performed on a small scale in a Wolfe's apparatus, with wide connecting tubes to prevent their being obstructed by the crystals; and on a large scale, in strong vessels, into which the carbonic acid may be driven by means of a forcing pump. During the progress of the saturation, the greater part of the silica which may happen to be associated with the alkali as an impurity, is precipitated; and hence the solution generally becomes turbid. It is to remove this earth that filtration is directed.

The processes of the different Pharmacopœias appear to have several defects. Both Mr. Phillips and Mr. Brande are of opinion that the carbonate should be dissolved in at least five times its weight of water, a quantity of menstruum requisite to accommodate the comparatively sparing solubility of the bicarbonate. The disadvantages of using too little water, are that some sesquicarbonate is apt to be generated, and that the bicarbonate is inconveniently precipitated, in the form of a crystalline deposite, in the progress of the operation. Hence it is that in the two first processes quoted, so far from evaporation being necessary, as directed by them, to form crystals, there is a deficiency of water in the product to hold the crystals already formed in solution. The Dublin process is less obnoxious to this objection; as a larger proportion of water is used, and no heat applied. The true principles which should regulate the strength of the alkaline solution, is to have sufficient water to prevent the premature crystallization of the solution, and yet so much as to render evaporation with much heat necessary to bring it to the crystallizing point. The evaporation, when performed, must be done at a gentle heat; as at a high temperature the salt loses one-fourth of its carbonic acid and becomes a sesquicarbonate.

According to Mr. Phillips, muriatic acid is preferable to sulphuric, for disengaging the carbonic acid from the carbonate of lime; inasmuch as the former generates a soluble salt, while the latter, by giving rise to the insoluble sulphate of lime, interferes with the rapid and complete decomposition of the calcareous salt. This writer also suggests that the muriate of lime may be decomposed by sulphuric acid so as to recover the muriatic acid for future employment. In small operations, there can be no doubt that the muriatic acid, diluted with twice its bulk of water, is most convenient; but whenever the carbonic acid gas is required in large quantities, the comparative cheapness of sulphuric acid will always give it the preference; and the clogging effect of the resulting sulphate of lime may be in a great measure obviated by the use of a proper agitator.

According to Berzelius, the cheapest method of obtaining the bicarbonate of potassa is to suspend a concentrated solution of the purified carbonate, contained in a stoneware dish, within a cask over a liquid undergoing the vinous fermentation. The alkali is thus surrounded by an atmosphere of carbonic acid, and by absorbing it, becomes bicarbonate in the course of five or six weeks, and crystallizes. The distillers particularly are enabled with great facility to prepare this salt by suspending the alkaline solution, over the wort, in the fermenting tun. The salt in powder called *sal æratus*, which is made in the New England States and perhaps elsewhere, is, we believe, prepared in this way. It is, however, not a perfect bicarbonate.

Properties, &c. Bicarbonate of potassa is in the form of white inodorous crystals, permanent in the air, and having the shape of flat irregular eight-sided prisms with two-sided summits. It has a slightly alkaline taste, and acts but feebly on vegetable colours. It dissolves in four times its weight of cold water, and in five-sixths of its weight of boiling water, by which it is partially converted into sesquicarbonate. It is very sparingly soluble in alcohol. Exposed to a low red heat, it loses half its carbonic acid, and returns to the state of carbonate, which, when thus obtained, is free from silica, and otherwise very pure. Dissolved in nitric acid, it should give a clear solution, the transparency of which is not disturbed by nitrate of silver, or carbonate of soda. When perfectly saturated, its solution does not precipitate a solution of sulphate of magnesia. With this exception, its incompatibles are nearly the same as those of the carbonate; but calomel is not decomposed by it; and it produces a white precipitate with corrosive sublimate, instead of the brick-red one caused by the regular carbonate. It consists of two equiv. of carbonic acid 44.24, one of potassa 47.15, and one of water 9=100.39. It is, therefore, properly a *bicarbonate*, not a *carbonate* as it is called by the London and Edinburgh Colleges. By an unfortunate confusion in nomenclature, the name "carbonate of potassa" is used in two senses in the different Pharmacopœias; and as this circumstance may cause some perplexity, we subjoin the following tabular statement, which shows at one view the exact import of the different officinal names.

Nature.	*U.S. and Dublin.*	*London.*	*Edinburgh.*
Ordinary carbonate.	Potassæ Carbonas.	Potassæ Subcarbonas.	Sub-Carbonas Potassæ.
Saturated carbonate.	Potassæ Bicarbonas.	Potassæ Carbonas.	Carbonas Potassæ.

Thus it is perceived that the term "carbonate of potassa" means the *ordinary carbonate* when used in the U.S. and Dublin Pharmacopœias, and the *saturated carbonate*, when employed by the London and Edinburgh Colleges.

The medical properties of this salt are the same as those of the carbonate, to which it is preferable on account of its milder taste, and greater acceptability to the stomach. The dose is from twenty grains to a drachm. B.

AQUA SUPER-CARBONATIS POTASSÆ. *Ed. Water of Super-Carbonate of Potassa.*

"Take of Water *ten pounds;* Purest Sub-Carbonate of Potassa [salt of tartar] *an ounce.* Dissolve, and expose the solution to a stream of Carbonic Acid gas, arising from Carbonate of Lime, in powder, Sulphuric Acid, each, *three ounces*, Water *three pounds*, gradually and cautiously mixed.

"The chemical apparatus invented by Dr. Nooth is well adapted for this preparation. But if a larger quantity of the liquor is required, an apparatus must be used capable of producing sufficient pressure. The solution should be kept in well stopped bottles." *Ed.*

This preparation may be considered as a bicarbonate of potassa dissolved in carbonic acid water; for from the great excess of carbonic acid present, the alkali probably passes into the state of bicarbonate. It is, however, altogether superfluous, in consequence of the general introduction into the shops of carbonic acid water (artificial Seltzer water), which may be readily employed for dissolving any desired proportion of the alkaline carbonate here employed, with the result of forming a much brisker preparation. This solution has the general sparkling qualities and acidulous taste of carbonic acid water; the alkaline taste of the carbonate being covered in a great measure by the large excess of carbonic acid. It is intended merely to furnish a grateful form for the administration of the carbonate of potassa. (See *Aqua Acidi Carbonici.*) B.

POTASSÆ NITRAS PURIFICATUM. *Dub. Purified Nitrate of Potassa.*

"Take of Nitrate of Potassa *one part.* Dissolve it in *two parts* of boiling Water, filter the solution, and set it aside, so that on cooling crystals may form." *Dub.*

The purified nitre of commerce is sufficiently pure for medicinal purposes; so that this formula of the Dublin College is entirely unnecessary. The properties of nitre, and the manner in which it is purified, have been fully explained under another head. (See *Potassæ Nitras.*)

Off. Prep. Æther Nitrosus, *Dub.* B.

SULPHAS POTASSÆ CUM SULPHURE. *Ed.* *Sulphate of Potassa with Sulphur.*

"Take of Nitrate of Potassa, in powder, and of Sublimed Sulphur, *equal weights.* Mix them well together, and inject the mixture, by small portions at a time, into a red-hot crucible. When the deflagration is over, allow the salt to cool, and place it in a glass vessel well stopped." *Ed.*

When the mixture, indicated in this formula, is thrown into a red-hot crucible, each successive portion melts, and the sulphur floats on the surface of the nitre with an appearance like a brown oil, burns vividly, and gives rise to a copious evolution of sulphurous acid gas. The product of the deflagration is a white friable mass, intermixed apparently with undecomposed sulphur.

The nature of this preparation has not been determined. On the supposition that it is a sulphate of potassa, mixed with a certain portion of sulphur, as the Edinburgh name implies, its formation may be thus explained. By the combined influence of the sulphur, and of the heat employed, the nitric acid of the nitre is totally decomposed, and is thus enabled to furnish sufficient oxygen to convert a portion of the sulphur into sulphuric acid, which, as soon as formed, combines with the base of the nitre, to form the sulphate of potassa. This is left mixed with a portion of sulphur, which has escaped combustion; but the greater part of the latter undergoes ordinary combustion, and is dissipated as sulphurous acid fumes.

Supposing the saline matter to be a sulphate containing a little free sulphur, this combustible is evidently used in great excess; but whether this excess is necessary to obtain the exact preparation desired by the Edinburgh College, it is not easy to determine. The late Dr. Duncan ascertained that the product amounted only to four-tenths of the materials employed. It is, therefore, smaller than it ought to be, even supposing that the residue consisted of nothing but sulphate of potassa.

Dr. Duncan was of opinion that the preparation under consideration cannot be viewed as a sulphuretted sulphate, and for the following satisfactory reasons. In the first place, it is more soluble in water than sulphate of potassa, and forms a yellowish solution, the water leaving undissolved only a small residue of a black colour, which is not sulphur. In the second place, it exhales during solution a sulphureous smell, and its taste is sulphureous. These facts seem to show that a small portion of sulphite of potassa is present in the preparation, or, at least, some sulphurous acid in a state of loose combination.

Properties, &c. This salt has an acid and sulphureous taste, and an acid reaction with test paper. When pulverized, it yields a pale yellowish-white powder. It is soluble in eight times its weight of cold water. It is, however, not a uniform preparation; different specimens, apparently prepared with equal care, exhibiting some points of difference in properties. It was called by the earlier chemists *sal polychrestus Glaseri.* Its other properties coincide generally with those of sulphate of potassa, which may be considered as its basis.

Medical Properties and Uses. The medical effects of this preparation differ but little, if at all, from those of sulphate of potassa. Its action on the system is stated by Dr. Duncan to resemble that of the sulphureous mineral waters which contain a portion of neutral salt. The dose is from half a drachm to a drachm. B.

POTASSÆ BISULPHAS. *Dub.* POTASSÆ SUPERSULPHAS. *Lond.* *Bisulphate of Potassa. Supersulphate of Potassa.*

"Take of Commercial Sulphuric Acid *two parts;* Carbonate of Potassa from Pearlash *a sufficient quantity;* Water *six parts.* Mix one part of the Sulphuric Acid with the Water, and saturate the mixture with the Carbonate of Potassa; then add the other part of the Acid to the liquor and evaporate it, so that on cooling crystals may form." *Dub.*

"Take of the salt which remains after the distillation of Nitric Acid *two pounds;* Boiling Water *four pints.* Mix, that the salt may dissolve, and filter. Then boil down the solution to one-half, and set it aside that crystals may form. Pour off the liquid, and dry the crystals on bibulous paper." *Lond.*

The Dublin process for forming this supersalt is more precise than the London, but at the same time less economical. The object being to obtain a salt, containing twice as much sulphuric acid as exists in the neutral sulphate, it is plain that by dividing the acid employed into two equal parts, and saturating one of these parts with potassa, the resulting neutral sulphate must be converted into a bisulphate by the addition of the other part. In explaining the London formula, it is only necessary to recall to the reader's attention, a part of the explanations given under the head of *Nitric Acid.* It was there stated, that for the proper decomposition of nitre, for the purpose of obtaining nitric acid, it was necessary to use two equiv. of sulphuric acid to one of the salt. Consequently, the salt which remains after the distillation of nitric acid is really a bisulphate, and only requires to be dissolved, and the solution filtered and duly evaporated, in order that it may be freed from accidental impurities and brought to the state of crystals. The quantity of water ordered by the London College is excessive, and causes a waste of time and fuel to dissipate it by subsequent evaporation. Two pints of water instead of four, would probably form a solution of the proper medium strength, and this reduction would supersede the necessity of subsequent evaporation. If the solution is evaporated to a pellicle, the salt, on cooling, concretes into a mass; and if it be too dilute, the excess of acid remains in the water, and sulphate of potassa is obtained.

Properties, &c. Bisulphate of potassa is a white salt, usually presenting the form of minute prismatic crystals, and having an extremely acid taste. It is soluble in twice its weight of cold water, and in less than its weight of boiling water. Alcohol does not dissolve it, but when added to an aqueous solution, precipitates the neutral sulphate. Exposed to the air, it effloresces slightly on the surface, and when moderately heated, it readily melts, and runs like oil. At a red heat, it loses water and its excess of acid, and is reduced to the state of neutral sulphate. From its excess of acid, it acts precisely as an acid on the carbonates, causing them to effervesce. It is incompatible with alkalies, earths, and their carbonates, and with many of the metals and most oxides. This salt was formerly called *sal enixum.* It consists of two equiv. of sulphuric acid 80.2, one of potassa 47.15, and two of water 18=145.35. The name of the Dublin College is, therefore, most precise.

Medical Properties and Uses. The bisulphate of potassa unites aperient properties with those of sulphuric acid, and may be given in cases of constipation with languid appetite, such as very often occurs in convalescence from acute diseases. Dr. Paris states that it forms a grateful adjunct to rhubarb. It answers, also, according to Dr. Barker, for preparing an aperient effervescing draught at little expense. Equal weights, a drachm for instance, of the bisulphate of potassa and carbonate of soda, may be dissolved separately, each in two fluidounces of water, then mixed, and taken in the state of effervescence. The dose of the bisulphate is one or two drachms. B.

POTASSÆ SULPHURETUM. *U.S., Lond., Dub.* SULPHURETUM POTASSÆ. *Ed.* *Sulphuret of Potassa.*

"Take of Sulphur *an ounce;* Carbonate of Potassa *two ounces.* Rub the Carbonate of Potassa, previously dried, with the Sulphur; melt the mixture, in a covered crucible, over the fire; then pour it out, and when cold, put it into a bottle, which is to be well stopped." *U.S.*

"Take of Washed Sulphur *an ounce;* Subcarbonate of Potassa *two ounces.* Rub them together, and place the mixture over the fire, in a covered crucible, until they unite." *Lond.*

"Take of Sub-Carbonate of Potassa *two parts;* Sublimed Sulphur *one part.* Rub them together, and put them into a large coated crucible, and having fitted on the cover, surround it cautiously with live coals, so that at length the mixture shall melt. Keep the mass in a very close phial." *Ed.*

"Take of Carbonate of Potassa *four parts;* Sublimed Sulphur *one part.* Having previously mixed them, put them in a crucible, fit a cover to it, and expose them to a heat gradually raised until they unite. Keep the Sulphuret in a well stopped bottle." *Dub.*

When carbonate of potassa is melted with an excess of sulphur, the carbonic acid is expelled. Three-fourths of the potassa are decomposed; its oxygen, by uniting with a part of the sulphur, generates sulphuric acid, which, by union with the undecomposed potassa, produces sulphate of potassa; while the potassium forms with the remaining sulphur a sulphuret of potassium, with more or less excess of sulphur. Thus the preparation under consideration, formerly called *hepar sulphuris* or *liver of sulphur*, is not a sulphuret of potassa, but a mixture of sulphate of potassa and sulphuret of potassium, with excess of sulphur. In the first three formulæ given above, the sulphur is melted with twice its weight of the carbonate; in the Dublin formula, with four times its weight. Berzelius says that the true *hepar* is formed by melting 100 parts of the carbonate with at least 94 of sulphur, and that the sulphuret of potassium formed contains five equiv. of sulphur to one of metal. These proportions give a great excess of sulphur, compared with those adopted in the Pharmacopœias. The ratio of the sulphur is smallest in the Dublin Pharmacopœia, in which it has been reduced to one-fourth the quantity directed in the edition of 1807. This proportion is evidently too small, and yet we are assured by Dr. Barker, that the present Dublin mode of preparing this compound is much preferable to the old one. Upon the whole, however, it seems probable that the proportion adopted by the other Pharmacopœias is most eligible; and we are the more inclined to this opinion, as it is recommended by M. Henry of Paris. The use of a large crucible, as directed by the Edinburgh College, is proper; as otherwise the extrication of the carbonic acid is apt to cause the fused mass to swell up so as to overflow. When the fusion is completed, the mass should be poured out on a marble slab, and as soon as it concretes, should be broken into pieces, and immediately transferred to a well stopped bottle.

The different Pharmacopœias use the carbonate of potassa from pearlash; but this is considered by some authorities as not sufficiently pure. In the process of M. Henry, which is stated to be the best that has yet been devised, the purest carbonate of potassa is employed. His formula is as follows. Mix two parts of real salt of tartar with one of roll sulphur reduced to powder, and put the mixture into flat-bottomed matrasses, which should be only two-thirds filled by it. These are placed on a sand-bath, at equal distances, and the fire is applied, so as, at first, to produce only a gentle heat, which is afterwards increased. Care must be taken that the necks of the matrasses do not become obstructed. The heat is continued, until the matter is brought to the state of tranquil fusion, when it is allowed to cool. The mass obtained is compact, smooth, and of a fine yellow colour, and is broken into pieces and preserved in close bottles.

Properties, &c. Sulphuret of potassa, when properly prepared, is a hard and brittle substance, having a nauseous, alkaline, and bitter taste. Its colour is liver-brown, and hence its former name of *hepar sulphuris.* It is inodorous when dry, but emits a slightly fetid smell when moist, owing to the extrication of a small portion of hydrosulphuric acid gas. It is completely soluble in water, forming a liquid of a deep orange colour. During its solution, the sulphuret of potassium, by means of the elements of water, becomes changed into hydrosulphate of potassa. By exposure to the air it attracts moisture, and the same change takes place more slowly. The solution is decomposed by the mineral acids, which combine with the potassa, extricate hydrosulphuric acid, and precipitate the excess of sulphur in the state of hydrate. It is also incompatible with the solutions of most of the metals, which are precipitated either as sulphurets or hydrosulphates. When this preparation is kept in bottles imperfectly stopped, it becomes white on the surface, in consequence of the oxidation of the elements of the sulphuret of potassium, which is thereby converted into sulphate of potassa. B.

Medical Properties and Uses. The sulphuret of potassa is said to be diaphoretic. It acts, moreover, as an antacid, and produces the general effects of sulphur upon the system. By some it is maintained to be sedative, and directly to reduce the action of the heart. The complaints in which it has been most advantageously employed are chronic rheumatism and gout, and various cutaneous affections. It has been given with less benefit in painters' colic, asthma, and chronic catarrh, and acquired a short-lived reputation as a remedy in croup, after the publication of the essay to which the prize offered by Napoleon for the best dissertation on this disease was awarded. It is said, in some cases of cancer, to have assisted the palliative operation of hemlock. In consequence of its property of forming insoluble sulphurets when mixed with the metallic salts, it has been proposed as an antidote for some of the mineral poisons, such as corrosive sublimate, arsenious acid, the salts of copper, and the preparations of lead. Orfila, however, has proved that it does not prevent the effects of these poisons, but on the contrary is itself highly poisonous when given in large doses. According to this author, it occasions death by corroding the stomach, and depressing the powers of the nervous system. Dissolved in water it has proved very efficacious as an external application in cutaneous diseases, and in scabies is an almost certain remedy. It may be used for this purpose in the form of lotion, bath, or ointment. For a lotion it may be dissolved in water in the proportion of from fifteen to thirty grains to the fluidounce, and for a bath, the same quantity or rather more may be added to a gallon of water. A very small proportion of muriatic or sulphuric acid may in either case be added to the solution.

The dose of the sulphuret of potassa is from two to ten grains, repeated several times a day, and given in pill with liquorice, or in solution with syrup. In infantile cases of croup, from one to four grains were given every three or four hours. W.

POTASSÆ SULPHURETI AQUA. *Dub.* *Water of Sulphuret of Potassa.*

"Take of Washed Sulphur *one part;* Water of Caustic Potassa *eleven parts.* Boil for ten minutes, and filter through paper. Keep the liquor in well stopped bottles. The specific gravity of this solution is 1.117." *Dub.*

When sulphur is boiled with a solution of caustic potassa, a part of the water is decomposed, and its elements, by uniting to separate portions of sulphur, give rise to hyposulphurous and hydrosulphuric acids, which, by combining with the alkali, form a hyposulphite and hydrosulphate of potassa in solution. Accordingly, this preparation is not a solution of sulphuret of potassa, as it is called by the Dublin College; neither is it identical with an aqueous solution of the preceding preparation, though its name would naturally lead to that supposition.

Properties, &c. This liquid has an unctuous feel and a deep orange colour. It is decomposed by acids, which cause an effervescence of hydrosulphuric acid,and a milky appearance from the precipitation of sulphur. Upon exposure to the air it is gradually converted into a solution of the sulphate of potassa. It has the same medical properties as the last preparation; and is used internally and externally for the most part in cutaneous eruptions. The dose is from ten minims to a fluidrachm, diluted with water, and given two or three times a day. When used as a bath it imparts an orange colour to the skin. B.

POTASSÆ TARTRAS. *U.S., Lond., Dub.* TARTRAS POTASSÆ, *Ed. Tartrate of Potassa. Soluble Tartar.*

"Take of Carbonate of Potassa *sixteen ounces;* Supertartrate of Potassa [cream of tartar] in powder, *three pounds;* Boiling Water *a gallon.* Dissolve the Carbonate of Potassa in the Water; then gradually add the Supertartrate of Potassa, until effervescence ceases. Filter the solution through paper; then evaporate it till a pellicle forms, and set it aside to crystallize. Pour off the water, and dry the crystals upon bibulous paper." *U. S.*

The *London* formula is essentially the same with the above, which was copied from it with some slight changes in phraseology.

"Take of Sub-Carbonate of Potassa *one part;* Super-Tartrate of Potassa *three parts,* or *a sufficient quantity;* boiling Water *fifteen parts.* Dissolve the Sub-Carbonate in Water, and gradually add to the solution the Super-Tartrate of Potassa in fine powder, so long as it excites effervescence, which generally ceases before three times the weight of the Sub-Carbonate has been added; then filter the solution when cold through paper, and after due evaporation set it aside to crystallize." *Ed.*

"Take of Carbonate of Potassa from Pearlash *five parts;* Bitartrate of Potassa [cream of tartar] *fourteen parts;* boiling Water *forty-five parts.* Add the Bitartrate of Potassa, in very fine powder, to the Carbonate of Potassa, dissolved in the Water. Filter the solution through paper, and evaporate it, so that on cooling crystals may form." *Dub.*

In these processes, the excess of acid in the supertartrate is saturated by the potassa of the carbonate, the carbonic acid is extricated with effervescence, and the neutral tartrate of potassa is obtained. On account of the greater solubility of the carbonate than the supertartrate, the former is taken in a stated quantity and dissolved, and the latter is added to the solution formed to full saturation. As the salts are mixed in this order, the case may be considered as one in which a definite portion of carbonate of potassa in solution is saturated by the excess of acid of the supertartrate; and this manner of viewing the reaction comes to the same thing. As the cream of tartar is sucessively added, the mutual action of the salts should be promoted by constant stirring; and the addition should be continued so long as effervescence takes place, which is a better mode of proceeding than to add any specified quantity of the supersalt; since, from its variable quality, it is impossible to adjust precisely the proportion applicable to all cases. It is necessary that the solution should be exactly neutral, or a little alkaline; and hence, if inadvertently too much cream of tartar is added, the proper state may be restored by adding a little of the alkaline carbonate. When the saturation has been completed, the solution is filtered to separate the tartrate of lime, which appears in white flocks, and which is always present in cream of tartar as an impurity. The evaporated liquor should then be placed in *warm* earthenware vessels, to ensure a slow refrigeration; and after remaining at rest for several days, the crystals begin to form. In order that the crystallization should proceed favourably, it is necessary, according to Baumé, that the solution should be somewhat alkaline. Iron vessels should not be used in any part of the process; as this metal is apt to discolour the salt.

The proportions of the carbonate to the supertartrate taken in the different formulæ, are somewhat different. In the U. S. and London process, the salts are to each other as 5 to 11.25; in the Edinburgh, as 5 to 15, and in the Dublin as 5 to 14. The equivalent quantities coincide most nearly with the proportions of the Dublin College.

Tartrate of potassa is sometimes made in the process for preparing tartaric acid. When thus obtained, the excess of acid in the supertartrate is neutralized by means of carbonate of lime; which generates an insoluble tartrate of lime, and leaves the neutral tartrate in solution, from which it may be obtained by evaporation and crystallization. (See *Acidum Tartaricum.*)

Properties, &c. Tartrate of potassa, prepared according to the officinal processes, is in the form of white crystals, which are slightly deliquescent, and usually have the shape of irregular six-sided prisms with dihedral summits. Its taste is cooling and bitterish. It dissolves in its weight of cold water, and in much less boiling water, and is soluble in 240 parts of boiling alcohol. Exposed to heat, it undergoes fusion, swells up, blackens, and is decomposed; being converted into carbonate of potassa. For medicinal use, it should always be crystallized; but as it ordinarily occurs in the shops, it it is in a white granular powder, obtained by evaporating the solution to dryness, while it is constantly stirred. In this state it is said to require four times its weight of water for solution. It is never purposely adulterated, but if it be obtained by evaporation to dryness, it is liable to contain an excess either of carbonate or of supertartrate of potassa, when it will have an alkaline or acid reaction. It is decomposed by all the strong acids, and many acidulous salts, which cause the precipitation of minute crystals of supertartrate of potassa, by abstracting one equiv. of alkali from two of the salt. It is composed of one equiv. of tartaric acid 66.48, and one of potassa 47.15=113.63. According to Berzelius, the crystals contain no water of crystallization.

Medical Properties and Uses. Tartrate of potassa is a mild cooling purgative, operating, like most of the neutral salts, without much pain, and producing watery stools. It is applicable to febrile diseases, and is occasionally combined with senna, the griping effects of which it has a tendency to obviate. The dose is from a drachm to an ounce, according to the degree of effect desired. B.

POTASSII IODIDUM. *U. S.* POTASSÆ HYDRIODAS. *Dub.* *Iodide of Potassium. Hydriodate of Potassa.*

"Take of Solution of Potassa *two pints*, Iodine *a sufficient quantity.* Apply a gentle heat to the Solution, and add by degrees sufficient Iodine to saturate the Potassa, and to impart a brown colour to the liquid. Then pass Hydrosulphuric Acid through the solution, in a proper vessel, till it loses its brown colour, and retains the odour of the Acid. Filter through paper, and having poured hot water upon the residue, again filter. Boil the filtered liquors for a short time that the Hydrosulphuric Acid may be driven off; then, if sulphur has been precipitated, remove it, and saturate any acid that may be present with the Solution of Potassa. Lastly, boil the liquor to dryness. Hydrosulphuric Acid is obtained from Sulphuret of Iron, by the addition of Sulphuric Acid diluted with four times its weight of water." *U. S.*

"Take of Iodine *one part;* Sulphuret of Iron, in coarse powder, *five parts;* Sulphuric Acid *seven parts;* Distilled Water *forty-eight parts;* Water of Carbonate of Potassa *a sufficient quantity;* Rectified Spirit *six parts.* Mix the Iodine by trituration with sixteen parts of the water, and put the mixture into a glass vessel. Pour the Acid, previously diluted with thirty-two parts of the Water, on the Sulphuret, contained in a matrass; and by means of a tube adapted to the neck of the matrass, and reaching to the bottom of the vessel containing the Iodine and Water, transmit the gas through the mixture, until the Iodine entirely disappears. Filter the liquor, and immediately evaporate it, by a superior heat, to one-eighth part, and again filter it. Then gradually add as much Water of Carbonate of Potassa, as will be sufficient to saturate the acid, which is known by the cessation of the effervescence. Then expose the mixture to heat, until the residual salt is dry and of a white colour. On this pour the Spirit, and dissolve by the aid of heat. Lastly, from the remaining salt, pour off the solution, evaporate it to dryness, and keep the residuum in a close vessel." *Dub.*

By these processes, hydriodate of potassa is obtained in solution, which by evaporation to dryness becomes iodide of potassium. The U.S. process is that recommended in 1825 by Dr. Turner of London. On adding iodine in slight excess to a warm solution of potassa, water is decomposed; and by its elements uniting with separate portions of iodine, iodic and hydriodic acids are generated, which by combining with the alkali, form severally the iodate and hydriodate of potassa in solution. In the next step of the process, the hydrosulphuric acid gas furnishes hydrogen to the elements of the iodic acid, and converts it into hydriodic acid and water, while the sulphur of the gas is precipitated, and is removed by filtration. The solution thus becomes one exclusively of hydriodate of potassa, and, upon being evaporated to dryness, yields iodide of potassium, in consequence of the hydriodate losing the elements of water. Should the solution at first contain an excess of iodine, the hydrosulphuric acid will convert this also into hydriodic acid, which would remain in excess; and hence the direction is given to saturate any superabundant acid with solution of potassa before evaporating to dryness.

The process which Berzelius recommends as the best, on account of its economy, resembles the one just described, and is as follows. Dissolve iodine in caustic potassa, until the liquid begins to be coloured. Then evaporate it sufficiently to cause the iodate to crystallize, and boil the mother water containing the hydriodate to dryness, so as to obtain the iodide of potassium, which must be fused, in order to convert any iodate of potassa present into iodide. Berzelius states, that the solution of the mixed iodic salts may be at once evaporated to dryness, and the dry mass fused, so as to obtain iodide of potassium, without first separating the iodate by crystallization; but that the process when thus conducted is liable to the objection, that, during the fusion, the mass bubbles up, and portions of it are thrown out of the vessel, giving rise to a loss.

In the Dublin process, a stream of hydrosulphuric acid gas being passed through water in which iodine is diffused, the gas becomes decomposed, its sulphur is precipitated, and its hydrogen, by combining with the iodine, generates hydriodic acid, which remains in solution. The sulphur being separated by filtration, and the solution duly concentrated, the acid is converted into hydriodate of potassa by saturating it with carbonate of potassa, the carbonic acid of which, by being extricated, causes the effervescence. By evaporation to dryness, the hydriodate in solution becomes the iodide of potassium. But lest it should be contaminated with iodate or carbonate of potassa, the dry mass is directed to be digested with a portion of rectified spirit (alcohol), which takes up the iodide of potassium, and leaves these salts behind. The alcoholic solution of the pure iodide is then evaporated to dryness, and is thus obtained in the solid state.

This process is not so eligible as that of the U.S. Pharmacopœia; as it requires the previous formation of hydriodic acid, and the use of alcohol. An easier process, according to Dr. Turner, than either of these, is to add iodine to the officinal sulphuret of potassa in solution, (which in this state may be considered as a hydrosulphate of potassa,) as long as sulphur is precipitated. The iodine, by its superior affinity, replaces the sulphur, and thus converts the hydrosulphate into the hydriodate of potassa. The chief objection to this process is that the product is contaminated with sulphate of potassa, an impurity always present in the officinal sulphuret.

The following process by MM. Baup and Caillot is stated by Chevallier to be generally followed in France, and to give a whiter product than any other. Introduce into a matrass or capsule 50 parts of distilled water and 10 of iodine, and add gradually 5 parts of bright iron filings. Heat the mixture gently, and stir it occasionally, until, from being of a deep brown colour, it becomes colourless, and then filter. By the reaction of the materials, a hydriodate of iron is formed in solution. This is then heated nearly to the boiling point, and accurately saturated by means of carbonate of potassa, the alkali of which forms a hydriodate in solution, and precipitates the oxide of iron. By a new filtration, separate the oxide of iron, and evaporate the filtered liquor to a pellicle in a porcelain capsule. By the cooling of the solution, crystals of iodide of potassium will be formed, which are to be washed with a little water, drained, and dried on bibulous paper with a gentle heat. The same salt may be obtained also, by a similar process to the above, merely substituting zinc for the iron.

Properties. Iodide of potassium is a deliquescent salt, of an opaque white colour, and acrid and slightly bitter taste. It generally crystallizes in cubes, but by careful evaporation may be obtained in pyramids. It is soluble in about two-thirds of its weight of cold water, and is converted in the act of dissolving into hydriodate of potassa. It dissolves freely also in alcohol, and when a hot saturated alcoholic solution is allowed to cool, it deposites the salt in crystals. Its aqueous solution is capable of taking up a large quantity of iodine, and becomes an ioduretted hydriodate of a deep brown colour. Exposed to heat, it fuses readily into a mass having a crystalline and pearly aspect, and at a red heat is volatilized without decomposition. This latter property furnishes the means of detecting any fixed impurity, and its solubility in alcohol renders easy the discovery of any foreign substance insoluble in that menstruum. The most usual impurities contained in this salt, are chloride of sodium, and iodate and carbonate of potassa. The latter salts may be detected by their insolubility in alcohol; and if upon distilling a small portion of the iodide with nitric acid, a liquid is obtained which is precipitated by nitrate of silver, it is proof of the presence of a chloride, which is probably chloride of sodium. Carbonate of potassa is sometimes fraudulently introduced; and the late Dr. Duncan made mention of a spurious iodide of potassium sold at one period in Scotland, which contained 64 per cent. of this carbonate. At present iodine is comparatively so cheap, that but little motive remains for the practice of these frauds.

Composition. Iodide of potassium consists of one equiv. of iodine 126.3, and one of potassium 39.15=165.45. It contains no water of crystallization, a circumstance which removes all ambiguity as to whether it is an iodide or hydriodate. The Dublin name of hydriodate of potassa is, therefore, erroneous as applied to the solid salt; and though it may be supposed to become a hydriodate by solution, the question here relates to a solid and not to a liquid.

Medical Properties and Uses. This salt exhibits the same medical properties as iodine, though in a less degree. The powers of iodine as a remedy, have been so fully detailed in another place, that we have very little to add here. (See *Iodinum.*) Dr Lugol considers it to be quite inferior to iodine as a therapeutical agent, and uses it, apparently, for no other purpose than to promote the solubility of iodine in water. It has, however, been preferred by some practitioners, for the purpose of producing the constitutional effects of iodine. Dr. Montgomery states it to have been used by Dr. De Renzy, of Ireland, with great success in hæmoptysis; and Dr. Graves, another Irish physician, employed it with success in a very obstinate erythematic swelling of the hand. The dose is from one to two grains, or from fifteen to thirty drops of a solution made by dissolving thirty-six grains of the salt in a fluidounce of distilled water. It is chiefly used as an external application in the form of ointment. (See *Unguentum Potassæ Hydriodatis.*)

Off. Prep. Unguentum Potassæ Hydryodatis, *Dub.* B.

* * *

PULPARUM EXTRACTIO.

Extraction of Pulps.

"Boil unripe pulpy fruits, and ripe ones if dry, in a small quantity of water, until they become soft; then express the pulp through a hair sieve, and boil it down to the consistence of honey, in an earthen vessel, over a gentle fire, stirring it continually in order to prevent it from burning.

"The pulp of *Cassia fistularis* is, in like manner, to be boiled out from the bruised pod, and afterwards reduced to a proper consistence by evaporating the water.

"The pulps of fresh ripe fruits are to be expressed through the sieve, without previous boiling." *Ed.*

"Fruits of which the pulps are to be extracted, if unripe, or ripe and dry, are to be boiled in a little water until they become soft. Then the pulps, expressed through a hair sieve, are to be slowly evaporated to a proper consistence." *Dub.*

"Set *pulpy fruits*, if unripe, or ripe and dry, in a moist place to soften; then express the pulps through a hair sieve; afterwards boil them with a gentle fire, frequently stirring; lastly, evaporate the water by means of a water-bath, until the pulps become of a proper consistence.

"Pour boiling water upon the bruised *Cassia Pods*, so that the pulp may be washed out, and press this first through a coarse sieve, and afterwards through a hair sieve; then evaporate by means of a water-bath until the pulp acquires a proper consistence.

"Of fruits which are ripe and fresh, express the pulp or juice through a sieve, without boiling." *Lond.*

There are very few fruits the pulps of which are now employed in pharmacy. For these few the directions of the Edinburgh and Dublin Colleges are greatly preferable to those of the London, which are indeed impracticable, as dried fruits often do not become sufficiently moist, by mere exposure in a damp place, to admit of the subsequent treatment ordered, and besides, would almost always become mouldy. W.

* * *

PULVERES.

Powders.

The form of powder is convenient for the exhibition of substances which are not given in very large doses, are not very disagreeable to the taste, have no corrosive property, and do not deliquesce rapidly on exposure. As the effect of pulverization is to expose a more extended surface to the action of the air, care should be taken to keep substances which are liable to be injured by such exposure, in closely stopped bottles. In many instances it is also important to exclude the light, which exercises a very deleterious influence over numerous medicinal agents when minutely divided. In relation to substances most liable to injury from these causes, the best plan is to powder them in small quantities and as they are wanted for use.

Powders may be divided into the *simple*, consisting of a single substance, and the *compound*, of two or more mixed together. The latter only are embraced under the present head. In the preparation of the compound powders, the ingredients, if of different degrees of cohesion or solidity, should be pulverized separately and then united. An exception, however, to this rule, is the employment of one substance to facilitate by its greater hardness the minute division of another, as in the *Powder of Ipecacuanha and Opium*. Deliquescent substances, and those containing fixed oil in large proportion, should not enter into the composition of powders, the former, because by absorbing moisture, they render the preparation damp and liable to spoil, the latter, because they are apt to become rancid, and impart an unpleasant odour and taste to the mixture.

The lighter powders may in general be administered suspended in water or other thin liquid; the heavier, such as those of metallic substances, require a more consistent vehicle, as syrup, molasses, honey, or some of the confections. Resinous powders, if given in water, require the intervention of mucilage or sugar.

The *Dublin College* gives the following general directions for the preparation of powders. "The substances to be powdered, having been previously dried, are to be beaten in an iron mortar. The powder is then to be separated by sifting it through a hair sieve, and is to be kept in close vessels." W.

PULVIS ALOES COMPOSITUS. *Lond., Dub. Compound Powder of Aloes.*

"Take of Extract of the Spiked Aloe [Socotrine aloes] *an ounce and a half;* Guaiac *an ounce;* Compound Powder of Cinnamon *half an ounce.* Rub the Aloes and the Guaiac, separately, into powder; then mix them with the Compound Powder of Cinnamon." *Lond.*

The *Dublin College* gives the same directions, substituting the hepatic for the Socotrine aloes, and their own aromatic powder for the compound powder of cinnamon of the London College.

The tendency of pulverized guaiac to concrete, and the excessively bitter taste of aloes, which is but imperfectly concealed by the aromatic addition, render the form of powder ineligible for the exhibition of these medicines. The preparation is a warm stimulant cathartic, but is little used. The dose is from fifteen to thirty grains. W.

PULVIS ALOES ET CANELLÆ. *U.S.* PULVIS ALOES CUM CANELLA. *Dub.* *Powder of Aloes and Canella.*

"Take of Aloes [hepatic, *Dub.*] *a pound;* Canella *three ounces.* Rub them separately into very fine powder [into powder, *Dub.*] and then mix them." *U.S., Dub.*

This preparation has long been known under the name of *hiera picra.* The canella serves to correct the griping property, and imperfectly to cover the taste of the aloes; but the unpleasant bitterness of the latter is still very obvious in the mixture, which would be better given in the form of pill than of powder. It is a popular remedy in amenorrhœa, and may be used for all the purposes to which aloes is applied. It is sometimes administered, in domestic practice, infused in wine or spirit. The dose is from ten to twenty grains. W.

PULVIS ALUMINIS COMPOSITUS. *Ed.* *Compound Powder of Alum.*

"Take of Alum *four parts;* Kino *one part.* Rub them together to a fine powder." *Ed.*

A solution of alum is decomposed by a solution of kino, and it is probable that the same effect takes place when the two substances, mixed in the state of powder, are introduced into the stomach: but whether their astringency is materially affected by the change is uncertain. The preparation may be employed in diarrhœa and menorrhagia, and externally to suppress hemorrhage, or as an astringent application to flabby indolent ulcers. The dose is from five to twenty grains. W.

PULVIS AROMATICUS. *U.S., Ed., Dub.* PULVIS CINNAMOMI COMPOSITUS. *Lond.* *Aromatic Powder.*

"Take of Cinnamon, Cardamom, Ginger, each, *two ounces.* Rub them together into a very fine powder." *U.S.*

The *Edinburgh* process corresponds with that of the U. S. Pharmacopœia. The *London College* directs two ounces of cinnamon, an ounce and a half of cardamom, an ounce of ginger, and half an ounce of long pepper; the *Dublin College*, two ounces of cinnamon, an ounce of cardamom seeds freed from their capsules, an ounce of ginger, and a drachm of long pepper.

The cardamom seeds should always, as directed by the Dublin College, be separated from their capsules; and the powder, when prepared, should be kept in well stopped bottles. The London and Dublin preparations are more pungent than that of the U. S. Pharmacopœia, in consequence of the long pepper which they contain. These powders are stimulant and carminative, and may be given in the dose of from ten to thirty grains, in cases of enfeebled digestion accompanied with flatulence; but they are chiefly used as corrigents and adjuvants of other medicines.

Off. Prep. Pulvis Aloës Comp., *Lond., Dub.;* Confectio Aromatica, *U. S., Ed.;* Confectio Opii, *U. S., Ed.* W.

PULVIS ASARI COMPOSITUS. *Ed., Dub.* *Compound Powder of Asarabacca.*

"Take of Leaves of Asarabacca *three parts;* Leaves of Marjoram, Lavender Flowers, each, *one part.* Rub them together into powder." *Ed.*

"Take of dried Leaves of Asarabacca *an ounce;* dried Lavender Flowers *a drachm.* Rub them together to powder." *Dub.*

This is an agreeable and efficacious errhine, useful in some cases of obstinate headach, toothach, and chronic ophthalmia. Five or six grains snuffed up the nostrils at bedtime, excite sneezing and a copious discharge of mucus, which continues to flow on the following day. W.

PULVIS CONTRAJERVÆ COMPOSITUS. *Lond. Compound Powder of Contrayerva.*

"Take of Contrayerva Root, in powder, *five ounces;* Prepared Oyster-shell *a pound and a half.* Mix them." *Lond.*

This powder unites the gently stimulant and diaphoretic properties of the contrayerva with the antacid properties of the oyster-shell; but the preparation is quite obsolete. W.

PULVIS CRETÆ COMPOSITUS. *Lond., Dub.* PULVIS CARBONATIS CALCIS COMPOSITUS. *Ed. Compound Powder of Chalk.*

"Take of Prepared Chalk *half a pound;* Cinnamon Bark *four ounces;* Tormentil Root, Gum Arabic, each, *three ounces;* Long Pepper *half an ounce.* Rub them separately into very fine powder, and then mix them." *Lond., Dub.*

"Take of Prepared Carbonate of Lime *four ounces;* Nutmeg *half a drachm;* Cinnamon Bark *a drachm and a half.* Rub them together to powder." *Ed.*

In the Edinburgh preparation, the aromatics are in too small a quantity to serve any other purpose than to communicate a pleasant flavour to the carbonate of lime, which is the only active ingredient. The powder of the London and Dublin Colleges is, on the contrary, warm, stimulant, and astringent, as well as antacid; and is well calculated for the treatment of diarrhœa, connected with acidity and unattended with inflammatory symptoms. In such a combination, however, the proper proportion, and even the choice of the ingredients, varies so much with the symptoms of the case, that they might with propriety be left to extemporaneous prescription. The dose of the compound powder of chalk is from ten to twenty grains, given in mucilage or sweetened water, and frequently repeated.

Off. Prep. Pulvis Cretæ Compositus cum Opio, *Lond., Dub.* W.

PULVIS CRETÆ COMPOSITUS CUM OPIO. *Lond., Dub. Compound Powder of Chalk with Opium.*

"Take of Compound Powder of Chalk *six ounces and a half;* Hard Opium, in powder, *four scruples.* Mix them." *Lond., Dub.*

The addition of the opium greatly increases the efficacy of the compound powder of chalk in diarrhœa; and its equal diffusion through the powder presents this advantage, that it may be conveniently given in minute doses applicable to infantile cases. Two scruples of the powder contain a grain of opium. In the diarrhœa of adults from ten to twenty grains may be given for a dose, and repeated several times a day, or after each evacuation. W.

PULVIS IPECACUANHÆ ET OPII. *U.S., Ed.* PULVIS IPECACUANHÆ COMPOSITUS. *Lond., Dub. Powder of Ipecacuanha and Opium. Dover's Powder.*

"Take of Ipecacuanha, in powder, Opium, in powder, each, *a drachm;* Sulphate of Potassa *an ounce.* Rub them together into a very fine powder." *U.S.*

All the British Colleges employ the same ingredients as above, and in the same proportions. The *London College*, having ordered them in the state of powder, simply directs them to be mixed together. The *Edinburgh* directions agree with those of our own Pharmacopœia, except that the opium is not pulverized before being rubbed with the other ingredients. The *Dublin College* first rubs the opium and sulphate of potassa together into powder, and then mixes the pulverized ipecacuanha with them.

The sulphate of potassa in this preparation serves, by the hardness of its particles, to promote that minute division and consequent thorough intermixture of the opium and ipecacuanha, upon which the peculiar virtues of the compound depend. It also serves to dilute the active ingredients and thus allow of their division into minute doses adapted to the complaints of children. This composition, though usually called Dover's powder, does not precisely correspond with that originally recommended by Dr. Dover, which is prepared as follows. Four ounces of nitrate of potassa and the same quantity of sulphate of potassa, are mixed together in a red-hot crucible, and afterwards very finely powdered; one ounce of opium, sliced, is then added, and ground to powder with the saline mixture; lastly, an ounce of ipecacuanha and an ounce of liquorice root, in powder, are mixed with the other ingredients. This process has been adopted in the Paris Codex.

The powder of ipecacuanha and opium is an admirable anodyne diaphoretic, not surpassed, perhaps, by any other combination in its power of promoting the cutaneous secretion. Opium itself has a strong tendency to the skin, evinced both by the occasional diaphoresis and by the itching and tingling sensation which it excites. While the vessels of the skin are stimulated by this ingredient of the powder, the secreting orifices are relaxed by the ipecacuanha, and the combined effect is much greater than that which results from either separately. At the same time the general stimulating influence of the opium, and its tendency to operate injuriously on the brain, are counteracted; so that the mixture may be given with safety in cases which might not admit of the use of opium alone. The preparation is applicable to all cases, not attended with much fever, or cerebral disease, or sick stomach, in which there is an indication for profuse diaphoresis, especially in painful affections, or those connected with unhealthy discharges. It is admirably adapted to the treatment of the phlegmasiæ, particularly rheumatism and pneumonia, when complicated with a typhoid tendency, or after a sufficient reduction of arterial excitement by the lancet or other mode of depletion. Under similar circumstances it is useful in dysentery, diarrhœa, and the various hemorrhages, especially that from the uterus. It is sometimes also given in dropsy. In the bowel affections, and whenever the hepatic secretion is deranged, it is frequently combined with small doses of calomel.

Ten grains of the powder contain one grain of opium. The dose is from five to fifteen grains, given diffused in water, or mixed with syrup, or in the form of bolus, and repeated at intervals of four, six, or eight hours, when it is desirable to maintain a continued diaphoresis. Its action may be materially promoted by warm drinks, such as lemonade, or balm tea, which, however, should not be given immediately after the powder, as they might provoke vomiting. W.

PULVIS JALAPÆ COMPOSITUS. *Ed., Dub.* *Compound Powder of Jalap.*

"Take of Jalap Root, in powder, *one part* [*half a pound*, Dub.]; Supertartrate of potassa *two parts* [*a pound*, Dub.]. Rub them together to a very fine powder." *Ed., Dub.*

The supertartrate, by being rubbed with the jalap, is thought to favour its more minute division, while it increases its hydragogue effect. A combination of these two ingredients, though with a larger proportion of cream of tartar, (see *Jalapa*,) is much used in this country as a cathartic in dropsy and scrofulous affections of the joints and glands. The dose of the officinal powder is from thirty grains to a drachm. W.

PULVIS KINO COMPOSITUS. *Lond., Dub.* *Compound Powder of Kino.*

"Take of Kino *fifteen drachms;* Cinnamon Bark *half an ounce;* Hard Opium *a drachm.* Rub them separately to very fine powder, and then mix them." *Lond., Dub.*

This is an anodyne astringent powder, useful in some forms of diarrhœa, but of which the composition would be better left to extemporaneous prescription, as the proportion of the ingredients should vary with the circumstances of the case. Twenty grains contain one grain of opium. The dose is from five grains to a scruple. W.

PULVIS OPIATUS. *Ed.* PULVIS CORNU USTI CUM OPIO. *Lond.* *Opiate Powder.*

"Take of Opium *one part;* Prepared Carbonate of Lime *nine parts.* Rub them together to a fine powder." *Ed.*

"Take of Hard Opium, in powder, *a drachm;* Hartshorn, burnt and prepared, *an ounce;* Cochineal, in powder, *a drachm.* Mix them." *Lond.*

These powders are intended to afford the means of exhibiting opium in minute doses; and it is of little consequence whether the carbonate or phosphate of lime is employed, although the antacid property of the former may in some instances prove advantageous. The cochineal of the London preparation merely serves to give it colour. Ten grains of the powder contain one grain of opium. W.

PULVIS PRO CATAPLASMATE. *Dub.* *Powder for a Cataplasm.*

"Take of Flaxseed which remains after the expression of the oil *one part;* Oatmeal *two parts.* Mix them." *Dub.*

This is a good material for the formation of poultices; but hardly deserves a place among the officinal preparations. The unpressed flaxseed meal is preferable to that which has been pressed, as the oil which it contains causes it to retain longer a soft consistence. W.

PULVIS SALINUS COMPOSITUS. *Ed., Dub.* *Compound Saline Powder.*

"Take of Muriate of Soda, Sulphate of Magnesia, each, *four parts;* Sulphate of Potassa *three parts.* Dry the salts with a gentle heat; then, having rubbed them separately to fine powder, mix them together, and keep the mixture in a well stopped bottle." *Ed., Dub.*

This is an aperient powder, and may be taken with advantage in costive habits, in the dose of two or three drachms, dissolved in half a pint of water or carbonic acid water, before breakfast. W.

PULVIS SCAMMONII COMPOSITUS. *Ed., Dub.* PULVIS SCAMMONEÆ COMPOSITUS. *Lond.* *Compound Powder of Scammony.*

"Take of Scammony, Hard Extract of Jalap, each, *two ounces;* Ginger Root *half an ounce.* Rub them separately to a very fine powder; and then mix them." *Lond., Dub.*

"Take of Scammony, Supertartrate of Potassa *equal parts.* Rub them together to a very fine powder." *Ed.*

It should be observed, that the compound of the Edinburgh College is essentially different from that of the London and Dublin Colleges; but we do not think that either of them is an eligible preparation. The cream of tartar in the former can serve little other purpose than to assist in the pulverization of the scammony, which does not require any peculiar care in this respect. In the latter, though the ginger may tend to correct the griping property of the purgative ingredients, the extract of jalap too closely resembles the scammony in its mode of operation to exert any important modifying influence upon it. The dose of the London powder is from seven to fifteen grains, of the Edinburgh, from ten to twenty grains. W.

PULVIS SENNÆ COMPOSITUS, *Lond.* *Compound Powder of Senna.*

"Take of Senna Leaves, Supertartrate of Potassa, each, *two ounces;* Scammony *half an ounce;* Ginger Root *two drachms.* Rub the Scammony separately, and the other ingredients together, to a very fine powder, and then mix them." *Lond.*

The cream of tartar in this preparation qualifies the action of the senna, while the scammony gives increased activity to the mixture, the dose of which would otherwise be too large for convenient administration. The ginger is added to prevent nausea and griping. The powder acts as a hydragogue cathartic in a dose varying from a scruple to a drachm. W.

PULVIS TRAGACANTHÆ COMPOSITUS. *Lond.* *Compound Powder of Tragacanth.*

"Take of Tragacanth, in powder, Gum Arabic, in powder, Starch, each, *an ounce and a half;* Refined Sugar *three ounces.* Rub the Starch and Sugar together to powder, then add the Tragacanth and Gum Arabic, and mix them all." *Lond.*

This is applicable to the general purposes of the demulcents; but is chiefly employed in Great Britain as a vehicle for heavy, insoluble powders. The dose is from thirty grains to a drachm, mixed with water or other mild liquid. W.

QUINIA.

Preparations of Quinia.

QUINIÆ SULPHAS. *U.S.* QUINIÆ SULPHAS. *Dub.* *Sulphate of Quinia.*

"Take of Yellow Bark, in powder, *a pound;* Lime, in powder, *four ounces;* Sulphuric Acid, Alcohol, Animal Charcoal, Distilled Water, each, *a sufficient quantity.* Boil the Bark for half an hour with eight pints of the Distilled Water, acidulated with a fluidounce of the Sulphuric Acid. Strain the decoction through linen; then boil the residue with the same quantity of acidulated Water, and filter as before. Mix the filtered liquors, and gradually add the Lime, stirring constantly. Wash the precipitate with Distilled Water, and having dried it, digest it in Alcohol with a moderate heat. Pour off the tincture, and repeat the digestion several times, till the Alcohol is no longer rendered bitter. Mix the tinctures and distil over the alcohol, till a brown viscid liquid remains in the retort. Upon this substance, removed from the retort, pour as much Sulphuric Acid, largely diluted with water, as may be sufficient for its perfect saturation. Then add the Animal Charcoal, and having evaporated the liquor sufficiently, filter it while hot, and set it aside to crystallize." *U.S.*

The process of the *Dublin College* is essentially the same with the above, though different in its details. Both were taken from the process of M. Henry Jun., of Paris, for which he received a prize from the French Academy of Sciences, and which, with some slight modifications, is now almost universally practised. This we shall present to our readers in full detail, premising, however, such an explanation of the more general directions of the U. S. Pharmacopœia, as may enable the student to understand each step of the process.

The yellow bark (Calisaya, or royal yellow) is the variety selected, because this contains quinia in the largest proportion, and most free from admixture with cinchonia. The alkali exists in the bark combined with kinic acid, and probably also, with one or more of the colouring principles, as suggested by M. Henry. As in this latter state it is of difficult solubility, if it be not insoluble in water, the whole of the quinia cannot be extracted from the bark by means of that liquid alone. Berzelius, however, attributes the difficulty of exhausting the bark to the circumstance, that water converts the native neutral kinates into soluble superkinates which are dissolved, and insoluble subkinates which remain. By adding sulphuric acid to the water in such quantities as to be in excess in relation to the quinia, the whole of the alkali combines with the acid to form a very soluble supersulphate, in which state it exists, together with various impurities, in the decoctions procured by the first steps of the process. By the addition of lime to the filtered and mixed decoctions, the sulphate is decomposed, giving up its sulphuric acid to the lime, while the quinia is liberated, and being insoluble in water, is precipitated in connexion with the sulphate of lime, the water retaining most of the impurities. The precipitate having been washed in order to purify it from every thing soluble in water, the next step is to separate the quinia from the sulphate of lime. This is accomplished by the agency of alcohol, which dissolves the former, and leaves the latter untouched. The whole of the alkali having been abstracted, the alcoholic solution of quinia is then sufficiently concentrated by evaporation, and diluted sulphuric acid added in such proportion as to form a neutral sulphate, which crystallizes when the liquor cools after concentration. The use of the animal charcoal is to deprive the salt of the colouring matter, which obstinately adheres to it through every stage of the process; and the object of the filtering is to separate the charcoal after it has performed this office. For the operator it is necessary to be acquainted not only with the outlines and general principles of a process, but with all its details, as the neglect of some points of little apparent importance may materially interfere with his success. It is to supply the deficiency of the process of the Pharmacopœia in this respect, that we introduce the following, extracted from the Dictionnaire des Drogues.

Process of M. Henry. Take 2000 parts of yellow bark, in powder, and 15,000 parts of water acidulated with 128 parts of sulphuric acid of 66° Baumé* Put the powder into a copper vessel, add a little water, make a paste by means of a wooden spatula; then mix this paste with the remainder of the liquid, place the vessel over the fire, and carry the heat to the point of ebullition. At the expiration of an hour, allow the acid decoction to rest, then strain it through linen, treat the residue with a fresh quantity of acidulated water, and strain as before. This treatment is to be repeated till the bark is exhausted, which may be known by the liquid ceasing to acquire bitterness. Now mix together all the decoctions, and add sufficient lime mixed with water to saturate the acid contained in the liquor. The quinia and cinchonia, separated from their combination with the acid, are precipitated along with the sulphate of lime, and the excess of lime added. Collect this precipitate upon a linen cloth previously moistened, taking care to preserve the liquid which passes through, as it still contains a portion of alkaline matter. To prevent the injurious reaction of the lime, contained in this liquor, upon the quinia, acidulate it slightly with sulphuric acid; then evaporate it one-third, and decompose the sulphate of quinia by an excess of lime. The precipitate now produced, is to be united with the first, and both are to be washed with water, till this ceases to acquire colour or taste; the water is then to be allowed to drain off, and the precipitate afterwards to be dried by a gentle heat. When perfectly dry it is to be powdered, and digested in alcohol of 36° Baumé, which, after some time, is to be decanted, and fresh portions successively added till they cease to extract any thing from the precipitate. Mix the alcoholic liquors, allow them to stand that the undissolved matter may subside, decant the clear portion, filter the remainder, introduce the whole into the water-bath of a still, and draw off three-quarters of the alcohol by distillation. There remains in the boiler a substance having the appearance of a resinous matter mixed with a small quantity of turbid liquor, which has a bitter taste and an alkaline reaction. Decant this liquor, and add to it water acidulated with sulphuric acid, so as to saturate the alkaline matter, taking care that the acid be not in excess. Litmus paper may be used to ascertain the neutrality of the mixture. During this operation the liquid should be kept hot. When it is allowed to cool, the sulphate of quinia precipitates. This is to be expressed, and boiled with water and a small quantity of animal charcoal previously washed with muriatic acid. After a few minutes of ebullition, filter the liquid while hot, and set it aside to crystallize. Drain the crystals, and afterwards dry them between folds of filtering paper at a temperature of 90° or 100° F. From the mother waters decolorized by charcoal, a new crop of crystals may be derived. A small quantity of sulphate of quinia may also be obtained from the viscid matter remaining in the water-bath of the still. For this purpose, saturate the matter with dilute sulphuric acid, evaporate one-half, add animal charcoal and boil for a few minutes, and lastly, filter the boiling liquid. On cooling, it deposites crystals which are to be treated as before described. The mother waters contain sulphate of cinchonia, with a proportion of sulphate of quinia which has not crystallized. They may be applied to important practical purposes. (See *Quiniæ Sulphas Impurus.*)

---

* Sufficiently near approximations are 4 troy pounds of bark, 24 pints of water, and 3 troy ounces of sulphuric acid.

The following modification of the above process has been proposed by M. Bernardet. In the distillation of the alcoholic solution, the whole of the alcohol is to be drawn off by means of a water-bath, and the viscid residue treated with about 100 parts of alcohol, which completely dissolves it. Three thousand parts of water heated in a water-bath and acidulated with sulphuric acid so as to tinge litmus paper of a deep red, are then to be added, and the liquor filtered. The filtered solution is next to be boiled with common animal charcoal, not previously washed with muriatic acid as in the former case, which removes the colour, and by the carbonate of lime which it contains, serves to neutralize the excess of sulphuric acid. To complete the process, it remains only to filter anew, and to evaporate sufficiently. The sulphate of quinia is thus obtained very pure and white.

Muriatic acid may be substituted in the process for the sulphuric.

Other processes have been proposed, and attempts have been made to extract the quinia without the use of alcohol; but none have been found to unite equally with that described, the important requisites of economy and convenience.

We have been informed by Mr. John Farr, of Philadelphia, who is largely concerned in the manufacture of sulphate of quinia, that the Calisaya bark employed by him, yields an average product of about two per cent. of the salt.

Sulphate of quinia may be obtained from any of the varieties of Peruvian bark by the above process; but should any other than the Calisaya bark be employed, a large proportion of sulphate of cinchonia will necessarily result from the operation, and, being much more soluble than the sulphate of quinia will remain dissolved in the residuary liquor from which the latter will have crystallized. To obtain the *cinchonia* separate, the following method, originally suggested by Pelletier and Caventou, may be employed. Magnesia, lime, or a solution of potassa as employed by M. Callaud, is added to the mother waters in excess. The cinchonia is precipitated together with a portion of quinia which has remained in the solution, and with the excess of magnesia or lime if one of these earths has been employed. The precipitate is collected on a filter, washed with hot water, then dried, and treated with boiling alcohol, which dissolves the vegetable alkalies. The alcoholic solution is filtered while hot, and the residue afterwards treated in the same manner with successive portions of alcohol, till it is quite exhausted. The solutions, having been mixed together, are now concentrated by the distillation of the alcohol, and allowed to cool, when they deposite cinchonia in the crystalline state. Successive evaporations and refrigerations afford new crops of crystals, and the process should be continued till no more can be obtained. The cinchonia thus procured, if impure, should be reconverted into a sulphate and treated as before, animal charcoal being employed to free it from colour. The quinia which remains in the mother waters, as it will not crystallize, may be obtained by evaporation to dryness, or may be converted into the crystallizable sulphate by the addition of sulphuric acid. To obtain the *sulphate of cinchonia*, mix the alkali with a small quantity of water, heat the mixture, and add gradually dilute sulphuric acid sufficient to saturate it; then boil with animal charcoal previously washed with muriatic acid, and filter the liquor while hot. Upon cooling it will deposite crystals of the sulphate, and by repeated evaporation and crystallization, will yield all the salt which it holds in solution.

Properties. Sulphate of quinia is in fine, silky, slightly flexible, needle-shaped crystals, interlaced among each other, or grouped in small star-like tufts. Its taste is intensely bitter, resembling that of the yellow bark. Exposed to a moderate heat, it loses its crystalline form in consequence of the escape of its water of crystallization. At a temperature of 212° it becomes luminous, especially when rubbed. At a still higher heat it melts, assuming the appearance of wax. It is very slightly soluble in cold water, requiring, according to M. Baup, 740 parts at 54° F. for solution, while at the boiling point it is dissolved in 30 parts. Its cold solution is opalescent. It is very soluble in alcohol, but only to a very small extent in ether. The diluted acids, even tartaric and oxalic acids, in excess, dissolve it with great facility. With sulphuric acid it forms a *supersulphate*, which is much more soluble in water than the neutral salt, and crystallizes from its solution with much greater difficulty. It is this salt which remains in the mother waters when an excess of acid is added in the process for procuring the sulphate of quinia. According to M. Baup, it is soluble in 11 parts of water at 54° F., and in its own water of crystallization at the boiling point. It is very soluble in diluted, and somewhat less so in absolute alcohol. The proportions of the constituents of the sulphates of quinia are stated somewhat differently by different chemists. We present the results as obtained by Robiquet. (*Dict. des Drogues.*)

Neutral Sulphate, Subsulphate of Berzelius.	
Sulphuric acid	10.
Quinia	80.9
Water	9.1

Supersulphate, Neutral Sulphate of Berzelius.	
Sulphuric acid	19.1
Quinia	63.5
Water	17.4

M. Baup, however, whose statement corresponds closely, so far as regards the proportions of the acid and base, with the analysis of Pelletier and Caventou, and is confirmed by the experiments of Winkler and of Buchner, gives as the constituents of the crystallized neutral sulphate, 76.272 parts of quinia, 8.474 of sulphuric acid, and 15.254 parts of water in the hundred. According to the same author, the neutral sulphate effloresces on exposure to the air, losing all but 2 or 3 per cent. of its water of crystallization, while the supersalt is permanent, unless heated or exposed to the action of substances having a strong affinity for water. (*Journ. de Pharm.* vii. 403.) When melted, it parts with all its water of crystallization. In this state it consists, according to Liebig, of 10 parts of acid, 85,83 of base, and 4.17 of water, which cannot be separated from it. By this chemist and by Berzelius it is considered as a subsulphate, consisting of two equiv. of quinia, one of sulphuric acid, and two of water.

Sulphate of quinia is decomposed by the alkalies and alkaline earths. In solution, it affords precipitates with potassa, soda, and ammonia, which are partly soluble in an excess of alkali. Tartaric, oxalic, and gallic acids, and their soluble salts, are said to precipitate the solutions of quinia; but these acids have no such effect on the sulphate if added in excess.

M. Henry asserts, that neither gallic acid nor a neutral gallate occasions a precipitate with the sulphate of quinia, and ascribes that which is formed by the tincture and infusion of galls to a combination of the quinia with tannin. Hence red wines, and astringent solutions generally, are incompatible with sulphate of quinia. (*Journ. de Pharm.* ii. 331.) The soluble salts of baryta occasion a precipitate insoluble in water and the acids.

Adulterations. The high price of sulphate of quinia has led to various attempts at adulteration. Sulphate of lime, sugar, mannite, starch, and stearin are among the substances which have been fraudulently added. By attending to the degree of solubility of the sulphate in different menstrua, and to its chemical relations with other substances already described, there can be little difficulty in detecting these adulterations. The presence of any mineral substance not readily volatilizable, may be at once ascertained by exposing the salt to a red heat, which will completely destroy the sulphate of quinia, leaving the mineral behind.

Medical Properties and Uses. Sulphate of quinia produces upon the system, so far as we are enabled to judge by observation, the same effects with Peruvian bark, without being so apt to nauseate and oppress the stomach. (See *Cinchona.*) It may, therefore, be substituted for that remedy in all diseases to which the latter is applicable; and in the treatment of intermittents it has proved so efficacious as to have almost entirely superseded the use of bark. It has the advantage over this remedy, not only that it is more easily administered in large doses, and more readily retained by the stomach, but that in cases which require an impression to be made through the rectum or the skin, it is much more effectual, because, from the smallness of its bulk, it is more readily retained in the former case, and more speedily absorbed in the latter. Still we cannot be certain that there are not other active principles in bark besides the quinia and cinchonia, the latter of which possesses properties analogous to those of the former; nor that the mode of combination in which these principles exist, may not so modify their action as to render them more effectual in certain forms of disease. The question can be solved only by careful and long continued observation. In the mean time, we may resort to the bark if the sulphate of quinia should not answer the ends in view; and instances have occurred under our own notice, in which it has proved successful in intermittents after the salt has failed.

The sulphate of quinia may be given in pill or solution, or suspended in water by the invention of syrup and mucilage. The form of pill is usually preferred. (See *Pilulæ Quiniæ Sulphatis.*) The solution may be readily effected by the addition of a little acid of almost any kind to the water. Eight grains of the sulphate will dissolve in a fluidounce of water acidulated with about twelve minims of the diluted sulphuric acid, or aromatic sulphuric acid of the Pharmacopœias; and this is the most eligible mode of exhibiting the medicine in the liquid form. The addition of a small proportion of sulphate of morphia or of laudanum, will often be found advantageous when the stomach is disposed to be sickened, or the bowels to be disturbed by the quinia.

Twelve grains of the sulphate of quinia are equivalent to about an ounce of good bark. The dose varies exceedingly, according to the circumstances of the patient and the object to be accomplished. As a tonic simply, a grain may be given three or four times a day, or more frequently in acute cases. In intermittents, from twelve to twenty-four grains should be given between the paroxysms, divided into smaller or larger doses according to the condition of the stomach or the length of the intermission. From one to four grains may be given at once, and some even advise the whole quantity. When the stomach will not retain the medicine, it may be administered with nearly as much efficacy by enema; from six to twelve grains with two fluidounces of liquid starch, and from twenty to forty drops of laudanum, being injected into the rectum every six hours. Should circumstances render this mode of application impracticable, an equal quantity, diluted with arrow root or other mild powder, may be sprinkled, at the same intervals, upon a blistered surface denuded of the cuticle. The epigastrium, or the inside of the thighs and arms, would be the proper place for the blister. W.

QUINIÆ SULPHAS IMPURUS. *U.S. Impure Sulphate of Quinia.*

"Evaporate the liquor, poured off from the crystals of Sulphate of Quinia, to the consistence of a pilular mass." *U.S.*

The only caution necessary in conducting this process, is to avoid such a degree of heat as would decompose the product to be obtained.

This preparation has been known and employed for several years in Philadelphia, under the absurd name of *extract of quinine.* Experience having fully proved its efficiency as a medicine, it was, with great propriety, introduced into the last edition of the U.S. Pharmacopœia, with a name, which, though not exactly expressive of its nature, has the merit at least of not being incorrect, and could not perhaps be supplied by a better.

It is of a dark brown colour, of a very bitter taste resembling that of quinia, and, when perfectly dry, is hard and brittle, breaking with a shining resinous fracture. It is partially soluble in water, entirely so in alcohol, and in water acidulated with sulphuric acid. Different views have been advanced in relation to its chemical nature. Sertürner, in the year 1829, announced that he had discovered in the mother waters, remaining after the crystallization of the sulphate of quinia, a peculiar alkaline principle which he called *chinoïdine*, and to which he ascribed extraordinary powers in the cure of disease. Having been in the habit for several years previously to this period, of employing the substance obtained by the evaporation of these waters, and having found its effects in all respects identical with those which we had been accustomed to procure from the salt of quinia, we could not but doubt the correctness of Sertürner's conclusions, and were quite prepared for the contradiction which they soon afterwards met with from MM. Henry Jun. and Delondre. By these chemists it has been satisfactorily shown, that what Sertürner mistook for a new alkali, was a mixture of cinchonia and quinia, with a peculiar yellowish resinoid matter, which prevented their crystallization. By the destruction of this matter, the nature of which has not been accurately investigated, the two alkalies were obtained separate. The active ingredients, therefore, of the preparation designated in the Pharmacopœia as the *impure sulphate of quinia*, are the sulphate of cinchonia and the sulphate of quinia.

Medical Properties and Uses. So far as we have been able to judge from much experience, the effects of this preparation upon the system are the same with those of the pure sulphate, for which it may be advantageously substituted in all cases in which the cost of medicine is a matter of much consequence. If we have discovered any difference, it is that the impure sulphate is rather more apt to prove offensive to the stomach. It was first employed by the late Dr. Samuel Emlen, about the year 1825, at the suggestion of Mr. John Farr, chemical manufacturer, of Philadelphia.

The dose is double that of the pure sulphate. It may be given in pill, (see *Pilulæ Quiniæ Sulphatis Impuri*,) or in the state of solution, or mixed with water by the intervention of mucilage. The solution may be readily effected by acidulating the water with sulphuric acid. We have seldom found intermittents to resist twenty-four grains of the impure sulphate given between the paroxysms; though a larger quantity may be employed with safety and greater certainty of success.

SODA.

Preparations of Soda.

SODÆ CARBONAS EXSICCATUS. *U.S.* SODÆ SUBCARBONAS EXSICCATA. *Lond.* SODÆ CARBONAS SICCATUM. *Dub.* *Dried Carbonate of Soda.*

"Take of Carbonate of Soda *any quantity*. Expose it to heat, in a clean iron vessel, until it is thoroughly dried, stirring constantly with an iron spatula; then rub it into powder." *U. S.*

The *London College* takes a pound of the salt and exposes it to a boiling heat; and in other respects treats it precisely as directed in the U.S. formula.

"Liquefy the crystals of Carbonate of Soda in a silver crucible over the fire. Then, having increased the heat, stir the liquefied salt, until, by the evaporation of the water, it becomes dry. Reduce it to fine powder, and keep it in close vessels." *Dub.*

Carbonate of soda contains ten equivalents of water of crystallization, and, when heated, readily undergoes the watery fusion. Upon continuing the heat, the water is dried off, and a white porous mass remains, which is easily reduced to powder, and constitutes the preparation under consideration. Dried carbonate of soda is in the form of a white powder, and differs in no respect from the carbonate, except in being devoid of water of crystallization. (See *Sodæ Carbonas.*)

Medical Properties and Uses. This preparation was introduced into regular practice on the recommendation of Dr. Beddoes, who extolled its virtues in calculous complaints. It is only applicable to the cure of such affections, when dependent on a morbid secretion of uric acid. Its advantage over the common carbonate is that it admits of being made up into pills, in consequence of being in the dried state. As the water of crystallization forms more than half of the carbonate, the dose of the dried salt must be reduced in proportion. From five to fifteen grains may be given three times a day in the form of pill, prepared with soap and aromatics. The general medical properties of this salt have been given under another head. (See *Sodæ Carbonas.*)

Off. Prep. Sodæ Sulphuretum, *U.S.* B.

SODÆ CARBONATIS AQUA. *Dub. Water of Carbonate of Soda.*

"Take of Carbonate of Soda, *any quantity.* Dissolve it in Distilled Water, so as to form a solution of the specific gravity 1,024. A solution of this density is obtained by dissolving *an ounce* of Carbonate of Soda in *a pint* of Distilled Water." *Dub.*

This preparation furnishes a solution of carbonate of soda of determinate strength, each fluidounce of which contains half a drachm of the salt. It is convenient for prescribing the alkali in solution, and forming effervescing draughts, each fluidounce being staturated, on an average, by half a fluidounce of lemon juice. The dose is from one to two fluidounces, sufficiently diluted with water, and given two or three times a day. B.

SODÆ BICARBONAS. *U.S., Dub.* SODÆ CARBONAS. *Lond.* CARBONAS SODÆ. *Ed. Bicarbonate of Soda.*

"Take of Carbonate of Soda [Subcarbonate, *Lond,*] *a pound;* Distilled Water *three pints.* Dissolve the Carbonate of Soda [Subcarbonate, *Lond.*] in the Distilled Water, and pass Carbonic Acid through the solution, till it is fully saturated; then set it aside to crystallize. Dry the crystals, wrapped in bibulous paper, and compressed. Evaporate the remaining solution with a heat not exceeding one hundred and twenty degrees, so that more crystals may be produced. Let these be compressed and dried in the same manner as the former." *U.S., Lond.*

"Carbonic Acid is obtained from Hard Carbonate of Lime, by the addition of Dilute Sulphuric Acid." *U.S.*

"Take of Sub-Carbonate of Soda *two parts;* Water *three parts.* Dissolve the Salt in the Water, and pass through it a stream of Carbonic Acid gas, until it ceases to be absorbed. Then filter the liquor, and evaporate with a heat not exceeding one hundred and eighty degrees, so that it may form a crystalline mass. Carbonic Acid is most easily obtained from equal weights of Carbonate of Lime in powder, and of Sulphuric Acid diluted with much water." *Ed.*

"Take of Carbonate of Soda *two parts;* Water *five parts.* Dissolve, and in a proper apparatus, expose the solution to a stream of Carbonic Acid gas, evolved during the solution of White Marble in dilute Muriatic Acid, until it ceases to absorb gas; and let it remain at rest that crystals may form. Then, with a heat not exceeding one hundred and twenty degrees, evaporate the solution that crystals may again be formed, which are to be mixed with those first obtained, dried, and preserved in a close vessel." *Dub.*

In these processes, the alkali combines with an additional quantity of carbonic acid, and a salt is formed, which, being less soluble than the original salt employed, precipitates in minute crystals. The solution poured off from these still contains a considerable quantity of the same salt, and hence the Pharmacopœias direct its evaporation by heat, so as to obtain a second crop of crystals. The heat should be as moderate as possible; but still, with the observance of every precaution, it is impossible to prevent the loss of some carbonic acid, whereby the salt is deteriorated, and rendered variable in composition. Under these circumstances, the lower heat directed in the U. S., London, and Dublin processes, is preferable to that prescribed by the Edinburgh College.

The principal objection to the officinal processes is, that so large a quantity of water is employed, as to make subsequent evaporation necessary. This may be avoided in several ways. Thus Dr. Thomson recommends that a concentrated solution of the ordinary carbonate should be suspended in a distiller's fermenting tun. In this case the bicarbonate, from its comparatively sparing solubility, and the small quantity of water used, is nearly all deposited in crystals. Berzelius gives a better process, as follows. Mix intimately four parts of the effloresced carbonate of soda with one part of the crystallized salt reduced to fine powder, and expose the mixture to the action of an atmosphere of carbonic acid gas, generated either in a liquid undergoing the vinous fermentation, (see p. 946), or by the decomposition of carbonate of lime by sulphuric acid. The saline matter obtained is then washed with cold water, to remove any carbonate which may not have been saturated. Berzelius does not explain why, in this process, the effloresced is mixed with the crystallized carbonate; but from the proportions employed, the reason, we think, is obvious; namely, to have present no more water of crystallization than can be taken up by the resulting bicarbonate. In this way, any excess of water is guarded against, which, by being liberated, might render it necessary to resort to evaporation, and thus hazard the partial decomposition of the salt.

The mode in which the salt under consideration is prepared in the United States, has been described by Mr. Franklin R. Smith, druggist of Philadelphia, in an interesting paper, published in the first volume of the Journal of the Philadelphia College of Pharmacy. As this mode is somewhat peculiar, we give an outline of the process, derived from Mr. Smith's paper. The ordinary carbonate of soda is placed in a box, and surrounded by an atmosphere of carbonic acid gas under pressure. As the bicarbonate combines with much less water of crystallization than is contained in the carbonate, a considerable portion of water is liberated, which, saturated with part of the salt, is allowed to drain off. When the gas ceases to be absorbed, the salt is taken out and dried. Upon examination it is found to have retained the original form of the pieces; but they have become of a porous and loose texture, presenting the appearance of numerous crystalline grains, aggregated together, and having a snow-white colour.

The above process, as Mr. Smith justly remarks, is much to be preferred to those of the Pharmacopœias, as solution and subsequent evaporation are entirely avoided; but the partial liquefaction of the salt, in consequence of the liberation of the water of crystallization, is an objection to it, which is obviated by the method already given from Berzelius, of having present only so much water of crystallization as may be necessary to accommodate the new salt formed.

Mr. Smith found, on analysis, that samples of reputed bicarbonate in our shops were intermediate, in the proportion of carbonic acid, between the bicarbonate and sesquicarbonate, and has shown that the variation depends upon the admixture of more or less of the ordinary carbonate. This he proved by washing a small portion of the recently prepared salt with a little water, which was found to remove carbonate; and the remaining salt, on analysis, proved to be the true bicarbonate. Mr. Smith then suggests that the process of our manufacturers might be improved by washing the saline product with a small quantity of water; and it is seen above, that in the process quoted from Berzelius, this course is adopted. For further details, the reader is referred to Mr. Smith's paper.

Properties, &c. This salt, prepared according to the officinal directions, is in the form of small crystals, or of a crystalline mass, of a snow-white colour and mild alkaline taste. It is soluble in thirteen times its weight of cold water; but boiling water decomposes it with disengagement of carbonic acid, and evaporation even at a gentle heat produces the same effect on its solution. If obtained by evaporation to dryness, if forms white crusts, and so much carbonic acid is lost as to reduce it to the state of sesquicarbonate. When exposed to a red heat, it loses the carbonic acid which it had acquired in the saturation, and returns to the state of ordinary carbonate. The salt, however, which passes under the name of "bicarbonate of soda" in the shops, is generally in the form of a white powder of uncertain composition, having been pulverised for the convenience of the apothecary. Of the perfect bicarbonate, every 84.54 parts lose, by complete decomposition by dilute sulphuric acid, 44.24 parts of carbonic acid. The incompatibles of this salt are the same with those of the ordinary carbonate, except that when fully saturated, it does not decompose the sulphate of magnesia without the aid of heat.

Composition. The officinal salt should consist of two equiv. of carbonic acid 44.24, one of soda 31.3, and one of water 9 = 84.54; but it seldom contains so large a proportion of carbonic acid. The first crop of crystals obtained in the U.S., London, and Dublin processes, may in the moist state, be considered as the true bicarbonate; but whenever the crystals are the product of evaporation, they contain less carbonic acid than the bisalt. The salt as procured by the method of our manufacturers is intermediate between the sesquicarbonate and bicarbonate, as determined by the analysis of Mr. Smith; while the product obtained by evaporation to dryness is a sesquicarbonate corresponding in nature with the carbonate of Egypt and Hungary, called *trona*. On account of its variable composition, it is difficult to give it an appropriate name; but "bicarbonate of soda," in allusion to what its composition ought to be when perfect, is, perhaps, the least exceptionable. With regard to the officinal nomenclature of carbonated soda, precisely the same confusion prevails, which has been explained under the head of bicarbonate of potassa. (See page 947.)

Medical Properties and Uses. This salt has the same medical properties as the ordinary carbonate, but, from its mild taste, proves more acceptable to the palate and stomach; while its superabundant acid has no power to interfere with its action as an alkaline remedy. It is often resorted to in calculous cases, characterised by predominant uric acid; and from its higher neutralizing power on account of the smaller equiv. of soda, it may be considered preferable as an antacid to the corresponding salt of potassa. It is principally employed in making what are called soda and Seidlitz powders. (See page 47.) It is sometimes made up into lozenges with sugar and gum Arabic, in the proportion of one part of the salt to nineteen of sugar, and employed as a remedy in indigestion arising from acidity. Several lozenges, each weighing twenty grains, may be taken at a time. The dose is from ten grains to a drachm, and is taken most conveniently in a glass of carbonic acid water. B.

AQUA SUPER-CARBONATIS SODÆ. *Ed.* AQUA CARBONATIS SODÆ ACIDULA. *Dub.* *Water of Super-Carbonate of Soda. Acidulous Water of Carbonate of Soda.*

"Take of Water *ten pounds;* Sub-Carbonate of Soda *two ounces.* Dissolve and pass through the solution a stream of Carbonic Acid gas, arising from powdered Carbonate of Lime, Sulphuric Acid, each, *three ounces,* Water *three pounds,* gradually and cautiously mixed. Nooth's apparatus is well adapted for this process. But if a larger quantity of this solution is required, an apparatus must be used capable of furnishing sufficient pressure. The solution should be kept in well stopped vessels." *Ed.*

"Take of Carbonate of Soda *any quantity.* Dissolve it in such a quantity of Water, that each *pint* may contain *a drachm* of Carbonate of Soda. Then, in an apparatus adapted for retaining the gas, subject it to a stream of Carbonic Acid gas, evolved during the solution of pieces of White Marble in Muriatic Acid, diluted with six times its weight of Water until the Carbonic Acid is in excess." *Dub.*

These preparations may be considered as solutions of bicarbonate of soda in carbonic acid water. They correspond with the solution formerly called *soda water,* which was made by impregnating under strong pressure, a weak solution of carbonate of soda with carbonic acid; but at present, this name is applied, in popular language, to carbonic acid water without soda. The solution formed according to the Edinburgh formula, contains about two drachms of the carbonate to a pint; which makes it twice as strong as the Dublin preparation. These solutions, however, are superfluous; as they may be made extemporaneously by adding any desired quantity of carbonate of soda to carbonic acid water. (See *Aqua Acidi Carbonici* and *Aqua Super-Carbonatis Potassæ.*) B.

SODÆ ET POTASSÆ TARTRAS. *U.S., Dub.* SODA TARTARIZATA. *Lond.* TARTRAS SODÆ ET POTASSÆ. *Ed.* *Tartrate of Potassa and Soda. Tartarized Soda. Rochelle Salt.*

"Take of Carbonate of Soda [Subcarbonate, Lond.] *twenty ounces;* Supertartrate of Potassa [cream of tartar], in powder, *two pounds;* Boiling Water *ten pints.* Dissolve the Carbonate of Soda in the Water, and gradually add the Supertartrate of Potassa. Filter the solution through paper; then evaporate it until a pellicle forms, and set it aside to crystallize. Pour off the liquor, and dry the crystals on bibulous paper." *U S., Lond.*

"Take of Sub-Carbonate of Soda *one part;* Super-Tartrate of Potassa *three parts,* or *a sufficient quantity;* Boiling Water *fifteen parts.* To the Sub-Carbonate, dissolved in the Water, gradually add the Super-Tartrate in fine powder, so long as it produces any effervescence, which commonly ceases before three times the weight of the Sub-Carbonate has been added. Then filter the liquor after it is cold through paper, and after due evaporation, set it aside that crystals may form." *Ed.*

"Take of Carbonate of Soda *five parts;* Bitartrate of Potassa [cream of tartar], in very fine powder, *seven parts;* Boiling Water *fifty parts.* Dissolve the Carbonate of Soda in the Water, and gradually add the Bitartrate of Potassa. Filter the liquor through paper, evaporate, and set it aside, so that on slow cooling crystals may form." *Dub.*

This is a double salt, consisting of tartrate of potassa combined with the tartrate of soda. The theory of its formation is exceedingly simple, being merely the saturation of the excess of acid in the bitartrate of potassa, by means of carbonate of soda, the carbonic acid of which, being extricated, causes the effervescence. The proper quantities of the materials for mutual saturation are 143.42 parts of carbonate to 189.11 of bitartrate, or one equiv. of each. This gives the ratio of 10 to 13.1. Now the carbonate is to the bitartrate as 10 to 12 in the U.S. and London formula, as 10 to 30 in the Edinburgh, and as 10 to 14 in the Dublin. The Dublin proportion is, therefore, the nearest to the theoretical quantities, while the Edinburgh presents a great excess of bitartrate, supposing the whole quantity directed to be employed; but if the directions of the Edinburgh College be strictly followed, the addition of the cream of tartar is desisted from as soon as effervescence ceases. As the salts employed are apt to vary in composition and purity—the carbonate from the presence of more or less water of crystallization, and the bitartrate from that of tartrate of lime—it is best in all cases, after giving the nearest average proportion as a general guide, to present to the operator the alternative of using the cream of tartar to the point of exact saturation.

Berzelius states that this salt may be formed by saturating six parts of cream of tartar by means of carbonate of potassa, and then adding to the resulting tartrate a solution of five parts of crystallized sulphate of soda. On evaporation, sulphate of potassa will first crystallize, and afterwards the tartrate of potassa and soda. The rationale is obvious.

Properties. Tartrate of potassa and soda is in the form of white, transparent, slightly efflorescent crystals, often very large, and having the shape, when carefully prepared, of right prisms, with ten or twelve unequal sides. As ordinarily crystallized, they are generally in half prisms, as if split in the direction of their axis. Its taste is saline and slightly bitter. It dissolves in two and a half times its weight of cold water, and in much less boiling water. (*Berzelius.*) When exposed to a strong heat, the tartaric acid is destroyed, and a mixture of the carbonate of potassa and soda is left. It sometimes contains tartrate of lime, which may be removed by solution and crystallization; but when its crystals are large and well defined, it may be assumed to be pure. It is incompatible with most acids, and with all acidulous salts except the bitartrate of potassa. It is also decomposed by the acetate and subacetate of lead, and by the soluble salts of lime and of baryta. The way in which acids act in decomposing it, is by combining with the soda, and precipitating bitartrate of potassa. This double salt was discovered by Seignette, an apothecary of Rochelle; and hence it is frequently called *Seignette's salt*, or *Rochelle salt*.

Composition. Tartrate of potassa and soda consists of two equiv. of tartaric acid 132.96, one of potassa 47.15, one of soda 31.3, and, according to Berzelius, ten of water 90=301.41; or, considered as a double salt, of one equiv. of tartrate of potassa 113.63, and one of the tartrate of soda 97.78, with the same quantity of water. According to some authorities, it contains only eight equivalents of water of crystallization; and Phillips and Brande have erroneously stated that it contains none. The probability is, that, according to the mode of crystallization, it may contain either eight or ten equiv. of water.

Medical Properties and Uses. This salt is a mild, cooling purgative, well suited to delicate and irritable stomachs, being among the least unpalatable of the neutral salts. As it is not incompatible with tartar emetic, it may be associated with that salt in solution. It is an ingredient in the effervescing aperient called Seidlitz powders, the composition of which is given at page 47. The dose is from an ounce to an ounce and a half. B.

SODÆ PHOSPHAS. *U.S.*, *Dub.* PHOSPHAS SODÆ. *Ed.* *Phosphate of Soda.*

"Take of Bone, burnt to whiteness and powdered, *ten pounds;* Sulphuric Acid *six pounds;* Carbonate of Soda *a sufficient quantity.* Mix the powdered Bone with the Sulphuric Acid in an earthen vessel; then pour in a gallon of water, and stir them well together. Macerate for three days, occasionally adding a little water to prevent dryness, and frequently stirring the mixture. At the expiration of this time, pour in a gallon of boiling water, and strain through linen, gradually adding more boiling water, until the acid is entirely washed away. Set by the strained liquor that the dregs may subside, from which pour off the clear solution, and boil it down to a gallon. To this solution, poured off from the dregs, and heated in an earthen vessel, add by degrees the Carbonate of Soda, previously dissolved in hot water, until effervescence ceases; then filter the liquor, and set it aside to crystallize. Having removed the crystals, add to the liquor, if necessary, a small quantity of Carbonate of Soda, so as accurately to saturate the phosphoric acid; then alternately evaporate and crystallize, so long as any crystals are produced. Lastly, preserve the crystals in a well stopped bottle." *U.S.*

The above is the *Edinburgh* process, with some slight changes in the details, and with the substitution of "gallon" for the quantity "nine pounds" wherever it occurs in the original.

"Take of burnt Bones, in powder, *ten parts;* Commercial Sulphuric Acid *seven parts.* Mix the powder, in an earthen vessel, with the Sulphuric Acid, and gradually add *seven parts* of water, and stir the mixture. Digest for three days, occasionally adding more water to prevent the matter from becoming dry, and continue the stirring: then add *seven parts* of boiling water, and strain through linen, repeatedly pouring on boiling water, until all the acid is washed out. Set the liquor by that the dregs may subside, from which pour it off when clear, and reduce it by evaporation to one-half. Then add *eight parts* of Carbonate of Soda, dissolved in hot water, and filter; and by alternate evaporation and refrigeration, let crystals be formed, which are to be kept in a well stopped vessel. If the salt be not sufficiently pure, dissolve it again in water, and recrystallize." *Dub.*

The incombustible part of bones, which is obtained by burning them to whiteness, consists of phosphate of lime, associated with some carbonate of lime, &c., and is generally called the earth of bones. (See *Os.*) When this is mixed with sulphuric acid, the carbonate of lime is entirely decomposed, giving rise to effervescence. The phosphate of lime undergoes partial decomposition; the greater part of the lime, being detached, precipitates as sulphate of lime, while the phosphoric acid set free, combines with the undecomposed portion of the phosphate, and remains in solution as a superphosphate of lime, holding dissolved a certain portion of the sulphate of lime. In order to separate the superphosphate from the precipitated mass of sulphate of lime, boiling water is added to the mixture, and the whole is strained, and the sulphate washed as long as superphosphate is removed, which is known by the water passing through in an acid state. The different liquids which have passed the strainer, consisting of the solution of superphosphate of lime, are mixed and allowed to stand, and by cooling a portion of sulphate of lime is deposited, which is got rid of by decantation.

The bulk of the liquid is now reduced by evaporation, and from the diminution of the water, a fresh portion of sulphate of lime becomes deposited, which is separated by subsidence and decantation as before. The superphosphate of lime is now saturated by means of carbonate of soda. The carbonic acid is extricated with effervescence, and the alkali, combining with the *excess* of acid of the superphosphate, generates phosphate of soda; while the superphosphate of lime, by the loss of its excess of acid, becomes the neutral phosphate, and precipitates. This precipitate is next separated by a new filtration; and the filtered liquor, consisting of the solution of phosphate of soda, is evaporated so as to crystallize.

In the U.S. and Edinburgh process, the calcined bone is to the acid as 10 to 6; in the Dublin process as 10 to 7. The proportion recommended by Berzelius is intermediate—as 10 to 6.66. The acid, in the officinal processes, is added to the bone in the concentrated state, and afterwards diluted with more or less water. In the process given by Berzelius it is first diluted with twelve times its weight of water. The Dublin College prescribes the quantity of carbonate of soda to effect the saturation; but the exact quantity cannot be known beforehand, and must vary under different circumstances. All the writers state that this salt crystallizes more readily by allowing its solution to be slightly alkaline; and what is remarkable is, that a neutral solution, when it crystallizes, leaves a supernatant liquid which is slightly acid and uncrystallizable. Hence it is necessary, after getting each successive crop of crystals, to render the mother water neutral or slightly alkaline, before it will furnish an additional quantity.

M. Funcke, a German chemist, has given the following method for obtaining phosphate of soda, which is stated to be cheaper and more expeditious than the process above described. Add to the powdered calcined bone, diffused in water, sufficient dilute sulphuric acid to decompose all the carbonate of lime which it may contain. As soon as the effervescence has ceased, the matter is acted on with nitric acid, which dissolves the phosphate of lime, and leaves the sulphate. The nitric solution of the phosphate is then treated with sulphate of soda, equal in quantity to the bone employed; and after the reaction is completed, the nitric acid is recovered by distillation. In consequence of a double decomposition, sulphate of lime and phosphate of soda are formed, the latter of which is then separated from the sulphate by the action of water, and crystallized in the usual manner.

Properties, &c. Phosphate of soda is in the form of large, white, efflorescent crystals, which have the shape of oblique rhombic prisms, and possess a pure saline taste, free from all bitterness. With tests, it displays a slight alkaline reaction. It dissolves in four times its weight of cold water, and twice its weight of boiling water. Before the blow-pipe, it first undergoes the aqueous fusion, and afterwards, at a red heat, melts into a globule of limpid glass, which becomes opaque on cooling. It is not liable to any adulterations, but sometimes contains carbonate of soda, from this salt being added in excess; in which case it will effervesce with acids. It is incompatible with neutral salts of lime, as also with neutral metallic solutions. This salt is found in several of the animal fluids, particularly the urine. When crystallized it consists of one equiv. of phosphoric acid 71.4, two of soda 62.6, and twenty-five of water 225=359. When heated gently, it loses twenty-four equiv. of water, retaining one equiv. which acts the part of a base. At a red heat this remaining equiv. of water is driven off, and the salt is altered in its properties, and becomes what is called the *pyrophosphate of soda.*

Medical Properties and Uses. This salt was introduced into regular practice about the year 1800, on the recommendation of Dr. Pearson of London. It is a mild purgative, and from its pure saline taste, is well adapted to the cases of children, and of persons of delicate stomach. The dose is from one to two ounces, and is best given in gruel, or weak broth, to which it communicates a taste, as if seasoned with common salt. B.

SODÆ SULPHURETUM. *U.S. Sulphuret of Soda.*

"Take of Sulphur *an ounce;* Dried Carbonate of soda *two ounces.* Mix them, and melt the mixture over the fire, in a covered crucible; then pour out the melted mass, and when it is cold, put it into a bottle, which must be well stopped." *U.S.*

This preparation is a mixture of sulphuret of sodium and sulphate of soda, which are formed in consequence of reactions precisely similar to those which occur in the preparation of sulphuret of potassa. (See *Potassæ Sulphuretum.*)

This sulphuret has the same medical properties as the sulphuret of potassa, and for this reason may be considered as a superfluous preparation in our Pharmacopœia. B.

SPIRITUS. *U.S., Lond., Dub.*

Spirits.

SPIRITUS STILLATITII. *Ed. Distilled Spirits.*

Spirits, according to the Pharmacopœia of the United States, are alcoholic solutions of volatile principles, obtained by distillation. By the London College the term is extended also to alcohol itself, and to certain solutions in that liquid prepared by simple maceration or digestion. The spirits are prepared chiefly from aromatic vegetable substances, the essential oils of which rise with the vapour of alcohol, and condense with it in the receiver. Some of the oils, however, will not rise at the temperature of boiling alcohol, but may be distilled with water. In this case it is necessary to employ proof spirit or diluted alcohol, with the water of which the oil comes over in the latter part of the process. As the proof spirit of the shops is often impregnated with foreign matters, which give it an unpleasant flavour, it is better to use alcohol which has been carefully rectified, and to dilute it with the due proportion of water, as directed by the U.S. Pharmocopœia. In preparing the spirits, care should be taken to avoid the colour and empyreumatic flavour arising from the decomposition of the vegetable matter by heat. Sufficient water must, therefore, be added to cover the vegetable matter after the alcohol shall have been distilled; and as a general rule, the heat should be applied by means of a water-bath, or of steam. It is proper that the aromatic should be macerated for some days with the alcohol, before being submitted to distillation; as the oil, being thus dissolved, rises more readily with the spirituous vapour, than when confined in the texture of the vegetable. It is necessary, during the process, frequently to renew the water in the refrigeratory, as otherwise a considerable portion of the vapour will escape condensation and be lost.

The aromatic spirits are used chiefly to impart a pleasant odour and taste to mixtures, and to correct the nauseating and griping effects of other medicines. They serve also as carminatives in flatulent colic, and agreeable stimulants in debility of stomach; but their frequent use may lead to the formation of intemperate habits, and should, therefore, be avoided.

The *Edinburgh College* gives the following general directions for the preparation of the distilled spirits. "To the substance to be distilled add nine pounds of Weaker Alcohol. Macerate for two days in a close vessel; then pour on sufficient water to prevent empyreuma, and distil nine pounds." W.

SPIRITUS AMMONIÆ FŒTIDUS. *Lond., Dub.* TINCTURA ASSÆFŒTIDÆ AMMONIATA. *Ed.* *Fetid Spirit of Ammonia.*

"Take of Spirit of Ammonia *two pints;* Assafetida *two ounces*. Macerate for twelve hours; then, by a gentle fire, distil a pint and a half into a cooled receiver." *Lond.*

"Take of Spirit of Ammonia *two pints;* Assafetida *an ounce and a quarter.* Macerate in a close vessel for three days, shaking occasionally; then pour off the clear liquor, and distil a pint and a half." *Dub.*

"Take of Ammoniated Alcohol *eight ounces;* Assafetida *half an ounce.* Digest in a close vessel for twelve hours; then distil eight ounces by the heat of boiling water." *Ed.*

This is a useless preparation. It differs from ammoniated alcohol only in containing a small proportion of the volatile oil of assafetida, which has little other effect than to communicate an unpleasant odour and taste to the spirit. It is colourless at first, but becomes brownish with age. W.

SPIRITUS AMMONIÆ SUCCINATUS. *Lond.* *Succinated Spirit of Ammonia.*

"Take of Mastich *three drachms;* Rectified Spirit *nine fluidrachms;* Oil of Lavender *fourteen minims;* Oil of Amber *four minims;* Solution of Ammonia *ten fluidounces.* Macerate the Mastich in the Spirit, that it may be dissolved, and pour off the clear tincture; then add the other ingredients, and shake them all together." *Lond.*

This was intended as a substitute for the *eau de luce.* It has a milky appearance, owing to the separation of the mastich from its alcoholic solution by the water of ammonia. Its properties are essentially those of the ammoniacal ingredient, the mastich having no medical action, and the oils of lavender and amber being in too small proportion to serve any other purpose than that of imparting flavour. It is used chiefly as a powerful stimulant, applied to the nostrils, in cases of fainting and torpor. The dose for internal use is from ten to thirty drops. W.

SPIRITUS ANISI. *Lond.* *Spirit of Aniseed.*

"Take of Anise Seeds, bruised, *half a pound;* Proof Spirit *a gallon;* Water *sufficient to prevent empyreuma.* Macerate for twenty-four hours; then, by a gentle fire, distil a gallon." *Lond.*

SPIRITUS ANISI COMPOSITUS. *Dub.* *Compound Spirit of Aniseed.*

"Take of Anise Seeds, bruised, Angelica Seeds, bruised, each, *half a pound;* Proof Spirit *a gallon;* Water *sufficient to prevent empyreuma.* Macerate for twenty-four hours, and distil a gallon." *Dub.*

The dose of this and the preceding preparation, as stomachics and carminatives, is one or two fluidrachms. The compound spirit is a simplification of the Irish *usquebaugh.* W.

SPIRITUS ARMORACIÆ COMPOSITUS. *Lond., Dub.* *Compound Spirit of Horse-radish.*

"Take of fresh Horse-radish Root, sliced, dried Orange Peel, each, *a pound;* Nutmegs, bruised, *half an ounce;* Proof Spirit *a gallon;* Water *sufficient to prevent empyreuma.* Macerate for twenty-four hours; then, by a gentle fire, distil a gallon." *Lond., Dub.*

This may be used advantageously as an addition to diuretic remedies, in dropsy attended with debility, especially in the cases of drunkards. The dose is from one to four fluidrachms. W.

SPIRITUS CARUI. *Lond., Dub.* SPIRITUS CARI CARUI. *Ed.* *Spirit of Caraway.*

"Take of Caraway Seeds, bruised, *a pound and a half* [a pound, *Dub.*]; Proof Spirit *a gallon;* Water *sufficient to prevent empyreuma.* Macerate for twenty-four hours; then, with a gentle fire, distil a gallon." *Lond., Dub.*

The *Edinburgh College* prepares the Spirit from half a pound of the bruised seeds, according to their general directions. (See page 977.) The dose as a carminative is one or two fluidrachms. W.

SPIRITUS CINNAMOMI. *Lond., Dub.* SPIRITUS LAURI CINNAMOMI. *Ed.* *Spirit of Cinnamon.*

"Take of Oil of Cinnamon, by weight, *five scruples;* Rectified Spirit *four pints and a half.* Add the Spirit to the Oil, and pour on them so much water, that, after the distillation, sufficient may remain to prevent empyreuma; then, by a gentle fire, distil a gallon." *Lond.*

"Take of Cinnamon Bark, bruised, *a pound;* Proof Spirit *a gallon;* Water *sufficient to prevent empyreuma.* Macerate for twenty-four hours, and distil a gallon." *Dub.*

By the *Dublin College* the spirit is also prepared by distilling together six scruples of the oil, and a gallon of proof spirit.

The *Edinburgh College* prepares it from a pound of bruised cinnamon, according to their general directions. (See page 977.)

The spirit of cinnamon is an agreeable aromatic cordial, and may be given in debility of stomach in the dose of one or two fluidrachms. W.

SPIRITUS COLCHICI AMMONIATUS. *Lond.* *Ammoniated Spirit of Meadow-saffron.*

"Take of Seeds of Meadow-saffron, bruised, *two ounces;* Aromatic Spirit of Ammonia *a pint.* Macerate for fourteen days, and filter." *Lond.*

This should be placed among the tinctures. It may be employed for the same purposes as the wine of colchicum, in cases which require or admit of an active stimulant. The dose is from thirty drops to a fluidrachm. The preparation, however, is scarcely ever used in this country. W.

SPIRITUS JUNIPERI COMPOSITUS. *U.S., Lond., Ed., Dub.* *Compound Spirit of Juniper.*

"Take of Juniper [berries], bruised, *a pound;* Caraway [seeds], bruised, Fennel-seed, bruised, each, *an ounce and a half;* Diluted Alcohol *a gallon;* Water *sufficient to prevent empyreuma.* Macerate for twenty-four hours; then, with a slow fire, distil a gallon." *U.S.*

The *London* and *Dublin* processes are essentially the same with the above; the *Edinburgh* differs in directing nine pounds of diluted alcohol, maceration for two days, and the distillation of nine pounds of spirit. According to the United States and London processes, the maceration is performed with both the diluted alcohol and water; according to those of Dublin and Edinburgh, only with the former, the water being added at the time of distillation.

This spirit is a useful addition to the diuretic infusions and mixtures in debilitated cases of dropsy. W.

SPIRITUS LAVANDULÆ. *U.S., Lond., Dub.* SPIRITUS LAVANDULÆ SPICÆ. *Ed. Spirit of Lavender.*

"Take of fresh Lavender [flowers] *two pounds;* Alcohol *a gallon;* Water *sufficient to prevent empyreuma.* Macerate for twenty-four hours; then, with a slow fire, distil a gallon." *U.S.*

The *London* process is the same with the above. The *Dublin College* employs a gallon of proof spirit, instead of rectified spirit or alcohol, and directs five pints only to be distilled. The *Edinburgh College* takes eight pounds of alcohol, and distils seven by means of a water-bath, omitting the addition of water to the materials.

The Dublin process, in which proof spirit is employed, is said to yield a product less highly impregnated with the oil of lavender than the others. Mr. Brande asserts that the dried flowers produce as fragrant a spirit as the fresh. Spirit of Lavender is used chiefly as a perfume, and as an ingredient in other preparations. The perfume usually sold under the name of *lavender water*, is not a distilled spirit, but an alcoholic solution of the oil, with the addition of other odorous substances. The following is given by Mr. Brande as one of the most approved recipes for preparing it. "Take of rectified spirit of wine five gallons, essential oil of lavender twenty ounces, essential oil of bergamotte five ounces, *essence of ambergris* (made by digesting one drachm of ambergris and eight grains of musk in half a pint of alcohol) half an ounce. Mix."

Off. Prep. Linimentum Camphoræ Compositum, *Lond., Dub.;* Spiritus Lavandulæ Compositus, *U.S., Lond., Ed., Dub.* W.

SPIRITUS LAVANDULÆ COMPOSITUS. *U.S., Lond., Ed., Dub. Compound Spirit of Lavender.*

"Take of Spirit of Lavender *three pints;* Spirit of Rosemary *a pint;* Cinnamon, bruised, *an ounce;* Cloves, bruised, *two drachms;* Nutmeg, bruised, *half an ounce;* Red Saunders, rasped, *three drachms.* Macerate for fourteen days, and filter through paper." *U.S.*

The *London College* omits the cloves, and directs half an ounce only of cinnamon; the *Edinburgh* employs pounds instead of pints, and macerates for seven instead of fourteen days; the *Dublin* orders half an ounce only of cinnamon and an ounce of red saunders; in all other respects, the processes of the British Colleges correspond with that of the U.S. Pharmacopœia.

This is a delightful compound of spices, much employed as an adjuvant and corrigent of other medicines, and as a remedy for gastric uneasiness, nausea, flatulence, and general languor or faintness. The dose is from thirty minims to a fluidrachm, and is most conveniently administered dropped on a lump of sugar. W.

SPIRITUS MENTHÆ PIPERITÆ. *Lond., Ed., Dub. Spirit of Peppermint.*

"Take of Oil of Peppermint, by weight, *six scruples and a half;* Rectified Spirit *four pints and a half.* Add the Spirit to the Oil, and pour upon them so much water, that, after the distillation, sufficient may remain to prevent empyreuma; then, by a gentle fire, distil a gallon." *Lond.*

The *Edinburgh College* prepares this spirit from one pound and a half of peppermint, according to their general directions. (See page 977.)

"Take of Oil of Peppermint, by weight, *half an ounce;* Rectified Spirit *a gallon.* Add the Spirit to the Oil, and pour on them so much water as will prevent empyreuma, after distillation; then, by a gentle fire, distil a gallon." *Dub.*

The effect of the London process is to afford a solution of the oil in proof spirit, as the difference between the four pints and a half of alcohol employed and the gallon distilled must be supplied by water added immediately before distillation. The same is the case with the spirit of spearmint, and the spirit of cinnamon of the same Pharmacopœia.

The spirit of peppermint has no advantage over a simple solution of the oil in alcohol. Such a solution, under the name of *essence of peppermint*, is usually kept in the shops, and is much employed as a domestic remedy. (See *Oleum Menthæ Piperitæ.*) W.

SPIRITUS MENTHÆ VIRIDIS. *Lond., Dub. Spirit of Spearmint.*

This is prepared by the *London* and *Dublin Colleges* from the oil of spearmint, in the manner directed by the two Colleges respectively for the preparation of the spirit of peppermint. The two spirits are used for the same purposes, in the dose of from thirty drops to a fluidrachm. W.

SPIRITUS MYRISTICÆ. *U.S., Lond.* SPIRITUS MYRISTICÆ MOSCHATÆ. *Ed.* SPIRITUS NUCIS MOSCHATÆ. *Dub. Spirit of Nutmeg.*

"Take of Nutmeg, bruised, *two ounces;* Diluted Alcohol [Proof Spirit, *Lond., Dub.*] *a gallon;* Water *sufficient to prevent empyreuma.* Macerate for twenty-four hours; then, with a slow fire, distil a gallon." *U.S., Lond., Dub.*

This spirit is prepared by the *Edinburgh College* from two ounces of bruised nutmeg, according to their general directions. (See page 977.)

The spirit of nutmeg is used chiefly for its flavour, as an addition to other medicines. The dose is one or two fluidrachms. W.

SPIRITUS PIMENTÆ. *U.S., Lond., Dub.* SPIRITUS MYRTI PIMENTÆ. *Ed. Spirit of Pimento.*

"Take of Pimento, bruised, *two ounces;* Diluted Alcohol [Proof Spirit, *Lond.*] *a gallon;* Water *sufficient to prevent empyreuma.* Macerate for twenty-four hours; then, with a slow fire, distil a gallon." *U.S., Lond.*

The *Dublin College* directs three ounces of pimento; in other respects its process is the same with the above.

The *Edinburgh College* prepares it from half a pound of bruised pimento, according to their general directions. (See page 977.)

This preparation may be used for the general purposes of the aromatic spirits, in the dose of one or two fluidrachms. W.

SPIRITUS PULEGII. *Lond., Dub. Spirit of European Pennyroyal.*

This is prepared by the *London College* from seven scruples *by weight* of the oil of pennyroyal, in the manner directed by the same College for the preparation of spirit of peppermint. The *Dublin College* prepares it by distilling together six scruples of the oil and a gallon of proof spirit. It is never used in this country. W.

SPIRITUS ROSMARINI. *U.S., Lond.* SPIRITUS RORISMARINI OFFICINALIS. *Ed.* SPIRITUS RORISMARINI. *Dub. Spirit of Rosemary.*

"Take of Oil of Rosemary [by weight] *an ounce;* Alcohol [Rectified Spirit, *Lond.*] *a gallon.* Add the Alcohol to the Oil, and pour on them so much water, that, after the distillation, sufficient may remain to prevent empyreuma; then, with a slow fire, distil a gallon." *U. S., Lond.*

The *Edinburgh College* takes two pounds of fresh rosemary tops and eight pounds of alcohol; and distils seven pounds by means of a water-bath.

The *Dublin College* employs a pound and a half of the fresh tops and a gallon of proof spirit, and distils five pounds with a moderate heat. This College also prepares the spirit by distilling together six scruples of the oil, and a gallon of proof spirit.

Spirit of rosemary is a grateful perfume, and is used chiefly as an ingredient in lotions or liniments.

Off. Prep. Linimentum Saponis Compositum, *Lond.*, *Dub.;* Spiritus Lavandulæ Compositus, *U.S.*, *Lond.*, *Ed.*, *Dub.* W.

SPONGIA.

Preparations of Sponge.

SPONGIA USTA. *U.S.*, *Lond.* Pulvis Spongiæ Ustæ. *Dub.* *Burnt Sponge.*

"Take of Sponge *any quantity.* Cut it into pieces, and beat it, that any extraneous adherent matters may be separated; then burn it in a close iron vessel until it becomes black and friable; lastly, rub it into a very fine powder." *U.S.*

The *London* and *Dublin* processes do not materially differ from the above.

The sponge is decomposed, the volatile matters being driven off by the heat, and a black friable coal remaining, which consists of charcoal mixed with phosphate and carbonate of lime, chloride of sodium, carbonate of soda, and iodine in the state of iodide of sodium. As the remediate value of burnt sponge depends chiefly upon the presence of iodine, it cannot be esteemed good unless it afford purple fumes when acted on by sulphuric acid assisted by heat. It is said that the preparation is most efficient as a remedy when the sponge is kept on the fire no longer than is necessary to render it friable. The powder is then of a much lighter colour. Guibourt recommends that the sponge selected for burning should be unwashed, of a strong odour, firm, and compact, that it should be put into a roaster similar to that sometimes used for coffee, and heated over a moderate fire till it becomes of a blackish-brown colour, that it should then be removed, powdered, and enclosed in a well stopped glass bottle. It is best when recently prepared, as the iodine is dissipated by time, and the specimens at first richest in this principle, contain little of it at the end of a year. (*Journ. de Chim. Med.*, *Dec.* 1831.)

Burnt sponge has been highly recommended in goitre, glandular swellings of a scrofulous character, and obstinate cutaneous eruptions. It is most conveniently administered mixed with syrup or honey, in the form of an electuary, with the addition of some aromatic, as powdered cinnamon. The dose is from one to three drachms. W.

STANNUM.

Preparations of Tin.

PULVIS STANNI. *U.S.* Stanni Pulvis. *Ed.*, *Dub.* *Powder of Tin.*

"Take of Tin *any quantity.* Melt it in an iron vessel over the fire, and, while it is cooling, stir it until it is reduced to a powder, which is to be passed through a sieve." *U.S.*

"Take of very pure Tin *any quantity.* Having melted it over the fire, agitate it strongly while congealing, so that it may be converted into a powder, which, when cold, is to be passed through a sieve." *Dub.*

The *Edinburgh College* has no formula for powdered tin, but includes it in the list of the Materia Medica.

Tin, being a very fusible metal, is easily granulated by fusion and subsequent agitation when in the act of congealing. The process is most conveniently performed, on a small scale, in a wooden box, the inside of which has been well rubbed with chalk. This may be afterwards washed away by water; and as the granulated powder is of unequal degrees of fineness, the coarser particles require to be separated by a sieve. For the properties of this metal see *Stannum.*

Medical Properties and Uses. Powder of tin is used exclusively as an anthelmintic, and is supposed to act by its mechanical properties. It is considered particularly adapted to the expulsion of the worm called *Ascaris lumbricoides*, and is sometimes employed to expel the tape worm; though for the latter purpose, oil of turpentine has proved more efficacious. For internal exhibition it ought always to be free from oxidation. The dose usually given is from one to two drachms, mixed with molasses, for several successive mornings, and then followed by a brisk cathartic. Dr. Alston, however, recommends much larger doses for the expulsion of tape worm. He begins by giving an ounce on an empty stomach, which is followed for two successive days with half an ounce each day, and finally by a brisk cathartic. B.

STYRAX.

Preparations of Storax.

STYRAX PURIFICATA. *U.S., Lond.* *Purified Storax.*

"Take of Storax, Alcohol, each, *a sufficient quantity.* Dissolve the Storax in the Alcohol, and strain the solution; then distil the Alcohol with a gentle heat, till the Storax acquires a proper consistence." *U.S.*

The purification of storax is directed by the *London College* in a similar manner.

Storax, as found in the shops, is usually so much adulterated as to render its purification necessary, before it can be applied to the purposes for which it is officinally directed. As it is wholly soluble in alcohol, and little of its active matter is driven off at the boiling point of that fluid, there can be no chemical objection to the above process. Another method, sometimes followed, is to express between heated iron plates the balsam from the foreign matters with which it is associated; but if the process be not very carefully conducted, the heat employed to melt the storax will be sufficient to dissipate a portion of the benzoic acid, which is one of its essential ingredients.

Off. Prep. Tinctura Benzoini Composita, *U.S.* W.

SULPHUR.

Preparations of Sulphur.

SULPHUR PRÆCIPITATUM. *U.S., Lond.* *Precipitated Sulphur.* *Milk of Sulphur.*

"Take of Sulphur [sublimed and washed] *a pound;* Lime, fresh burnt, *two pounds;* Muriatic Acid *a sufficient quantity;* Water *four gallons.* Boil the Sulphur and Lime together in the Water; then filter the solution through paper, and drop into it sufficient Muriatic Acid to precipitate the Sulphur. Lastly, wash the precipitate repeatedly with water till it becomes tasteless." *U.S.*

The *London* formula is essentially the same with the above, which was copied from it with a slight variation in the enumeration of the materials, to accommodate it to the plan of our Pharmacopœia.

In this process, water is decomposed, and its elements, by combining with separate portions of sulphur, give rise to bisulphuretted hydrogen and hyposulphurous acid, which, uniting to the lime, form a sulphuretted hydrosulphate and hyposulphite of lime. When muriatic acid is added to the filtered solution, muriate of lime is formed, a slight disengagement of sulphuretted hydrogen takes place, and sulphur is precipitated in the state constituting the preparation under consideration. The chief source of the precipitated sulphur is undoubtedly the excess present in the sulphuretted hydrosulphate; but it may be deemed probable, since sulphuretted hydrogen is but slightly disengaged, that the hydrosulphuric and hyposulphurous acids, upon being set free by the muriatic acid, react on each other, so as to form water and a fresh portion of sulphur. A simpler way of explaining the process, is to suppose that the lime unites directly with the sulphur, so as to form a sulphuret of lime in solution, a compound for which we have analogies in the existence of the chlorides of lime and soda. Assuming this to be the nature of the solution, the muriatic acid merely combines with the lime and precipitates the sulphur. This acid is the most eligible precipitant for the sulphur, as it forms with lime a very soluble salt, which is easily washed away. Sulphuric acid is altogether inadmissible for the purpose; as it forms an insoluble salt with lime, which becomes necessarily intermingled with the sulphur.

Properties, &c. Precipitated sulphur is in the form of white friable lumps of a pale yellowish-green tint, consisting of smooth, finely divided particles, slightly cohering together and devoid of taste, but possessing, when recently prepared, a peculiar smell. From its colour it was formerly called *lac sulphuris.* It is insoluble in water, but dissolves in a boiling solution of caustic potassa. When of a brilliant white colour, the presence of sulphate of lime may be suspected, in which case the sulphur will not be totally volatilized by heat. We have seen a sample of so-called precipitated sulphur, which consisted almost entirely of sulphate of lime. It differs from sublimed sulphur, in being in a state of more minute division, and, after being melted, in presenting a softer and less brittle mass. Its peculiarities probably depend upon the presence of water, which, however, is in too small a quantity to constitute a regular *hydrate*, as it is sometimes supposed to be.

Medical Properties and Uses. Precipitated sulphur possesses the same medical properties with sublimed sulphur, but is preferred by some practitioners on account of its smoothness and freedom from colour. Its state of extreme division renders it more readily suspended in liquids than sublimed sulphur; and its mode of preparation ensures it against the presence of acidity. It is sometimes selected for forming ointments, which have the advantage of appearance, in being of a lighter colour than when made of sublimed sulphur. The dose is from two to three drachms. (See *Sulphur.*)

B.

OLEUM SULPHURATUM. *Lond., Ed.* *Sulphurated Oil.*

"Take of Washed Sulphur *two ounces;* Olive Oil *a pint.* To the Oil previously heated in a very large iron vessel, gradually add the Sulphur, and stir them constantly with a spatula till they unite." *Lond.*

"Take of Olive Oil *eight parts;* Sublimed Sulphur *one part.* Boil them together, with a gentle fire, in a large iron pot, stirring them constantly till they unite." *Ed.*

The iron pot should be sufficiently large to hold three times the quantity of the materials employed, as the mixture might otherwise boil over. As the vapours which rise are apt to take fire, a lid should be at hand, to cover the pot, and thus extinguish the flame, should the accident take place. Sulphur is soluble to a considerable extent in heated oil, from which, if the solution be saturated, it is deposited in the crystalline state on cooling. But it is not a mere solution which this process is intended to effect. The oil is partly decomposed, and the resulting preparation is an extremely fetid, acrid, viscid, reddish-brown fluid, formerly known by the name of *balsam of sulphur.* In order that it may be obtained, the oil must be heated to the boiling point.

Sulphurated oil was formerly thought useful in chronic catarrh, consumption, and other pectoral complaints; but inconvenience has arisen from its acrid and irritating properties, and its internal use has been abandoned. It is said to be sometimes applied as a stimulant to foul ulcers. The dose is from five to thirty drops. W.

* * *

SYRUPI.

Syrups.

Syrups are concentrated solutions of sugar in watery fluids, either with or without medicinal impregnation. When the solution is made with pure water, it is named *syrup* or *simple syrup*, when with water charged with one or more medicinal agents, it is called in general terms a *medicated syrup*, and receives its particular designation from the substance or substances added.

Medicated syrups are prepared by incorporating sugar with vegetable infusions, decoctions, expressed juices, fermented liquids, or simple aqueous solutions. When the active matter of the vegetable is not readily soluble in water, or is volatilized or decomposed by a heat of 212°, it is sometimes extracted by diluted alcohol, the spirituous ingredient of which is subsequently driven off. Medicated syrups are also occasionally prepared by adding a tincture to simple syrup and evaporating the alcohol.

The quality and quantity of the sugar employed are points of importance. Refined sugar should always be preferred, as it often saves the necessity of clarification, and makes a clearer and better flavoured syrup than the impure kinds. The U.S. Pharmacopœia simply directs sugar, but explains that it is the purified or refined sugar which is indicated by that term. In relation to the quantity of sugar, if in too small proportion, fermentation is apt to occur, if too abundant, crystallization. The proper proportion is about two parts to one of the liquid. A somewhat smaller quantity will answer where acids, such as lemon juice or vinegar, are used.

As it is desirable, in many instances, that the active matters should be in as concentrated a state as possible in the syrup, it is often necessary to evaporate a large proportion of the watery fluid in which they are dissolved. This may be done either before the addition of the sugar or afterwards. In either case, care is requisite not to employ a heat too great or too long continued, lest the active principles should be injured. When these are very volatile or easily decomposed by heat, it is necessary to dispense with concentration altogether. Some substances which are volatilized or decomposed at the temperature of boiling water, remain fixed and unaltered at that which is necessary for the evaporation of alcohol. These, as before observed, may be dissolved in diluted alcohol, and the concentration effected by evaporating the spirituous part of the solvent. Independently of the injury which the medicinal ingredient of the syrup may sustain, the syrup itself is apt to become brown by a long continued application of heat, even when the degree is not excessive. It is recommended, therefore, that syrups which admit of concentration, should be boiled briskly over a lively fire, so as to accomplish the object as quickly as possible. It is important to be able to ascertain positively when they have attained the due consistence. An operator skilled in their preparation can judge with sufficient accuracy by various familiar signs;—such as the slowness with which the parts of a drop of syrup coalesce when previously separated by the edge of a blunt instrument; and the receding of the last portion of each drop, when the syrup, after being cooled, is poured out drop by drop. A pellicle forming upon the surface of the syrup when it cools, indicates that it has been too much boiled. But these signs are not to be relied on except by those who have acquired much experience. The easiest method of ascertaining the proper point of concentration is by the use of Baumé's hydrometer. This should stand at 30° in boiling syrup (30½ in hot weather), and at 35° in the syrup when it is cool. Another very accurate though less ready method is to ascertain the sp. gr. by weighing a portion of the liquid. Syrup when boiling should have a sp. gr. of about 1.261—when cold, about 1.319. Thomson and Duncan are mistaken in giving the proper sp. gr. of cold syrup as 1.385. We found that of a specimen of simple syrup made with two pounds and a half of sugar to a pint of water, to be 1.326 at 68° F.; and this consistence is rather too great for practical convenience in cold weather. A third method of ascertaining the proper point of concentration is by the thermometer, which, in boiling syrup of the proper consistence, stands at 221° F. This indication is founded on the fact, that the boiling point of syrup rises in proportion to the increase of its density.

When carefully prepared with double refined sugar, syrups generally require no other clarification than to remove any scum which may rise to their surface upon standing, and to pour them off from any dregs which may subside. Should they, however, want the due degree of clearness, they may be filtered through flannel, or, when not likely to be injured by the treatment, may be clarified by means of the white of eggs or animal charcoal, as mentioned under the head of *Syrupus*.

The medicated syrups are liable to undergo various alterations according to their nature and mode of preparation. The acid syrups, when too much boiled, often let fall a copious white precipitate, which is said to be a saccharine matter analogous to the sugar of grapes, produced by the reaction of the acid upon the sugar. Those which contain too little sugar are apt to pass into the vinous fermentation, in consequence of the presence of matters which act as a ferment. Those which contain too much, deposite a portion in the crystalline state, and the crystals, attracting the sugar remaining in solution, gradually weaken the syrup, and render it liable to the same change as when originally made with too little sugar. The want of a due proportion of saccharine matter frequently also gives rise to mouldiness, when air has access to the syrup. It is said that syrups, enclosed, while they are still hot, in bottles, are apt to ferment, because the watery vapour, rising to the surface and there condensing, diminishes the proportion of sugar, so as to produce a commencement of chemical action, which gradually extends through the whole mass. When syrups undergo the vinous fermentation, they become covered at the surface with froth, produced by the disengagement of carbonic acid, and acquire a vinous odour from the presence of alcohol; while their consistence is diminished by the loss of a portion of the sugar which has been converted into that liquid. When the quantity of alcohol has increased to a certain point, the fermentation ceases or goes on more slowly, owing to the preservative influence of this principle; and as the active ingredient of the syrup has frequently undergone no material change, the preparation may often be recovered by boiling so as to drive off the alcohol and carbonic acid, and concentrate the liquid sufficiently. A syrup thus revived is less liable afterwards to undergo change, because the principles which acted as ferments have been diminished or consumed. It is obvious that syrups which depend for their virtues upon a volatile ingredient, or one readily changeable by heat, cannot be restored to their original condition.

At best, syrups are too apt to change, and various measures have been proposed for their preservation. According to Dr. Macculloch, the addition of a little sulphate of potassa, or of chlorate of potassa, which is a tasteless salt, prevents their fermentation. M. Chereau has found the sugar of milk effectual to the same end, in the instance of the syrup of poppies; and it may prove useful in others. The proportion which he employs is 32 parts of the sugar of milk to 1000 of the syrup. But the best plan is to make small quantities at a time, and to keep them, unless when wanted for immediate use, in bottles quite full and well stopped, which should be put in the cellar or other cool place. The *London College* directs that "syrups be kept in a place where the temperature never exceeds 55°." It would be difficult to comply with such a rule in this country.

In relation to the preparation of syrups, the *Dublin College* gives the following general directions. "When no mention is made of the weight of sugar or the mode of dissolving it, syrups are to be prepared according to the following rule. Take of Refined Sugar, in fine powder, *twenty nine ounces;* the Liquor prescribed *a pint.* Add the Sugar by degrees, and digest it with a medium heat [from 100° to 200° F.] in a covered vessel, frequently shaking, till it is dissolved; then set aside the solution for twenty-four hours; remove the scum, and pour off the syrup from the dregs if there be any." W.

SYRUPUS. *U.S.* SYRUPUS SIMPLEX. *Lond., Ed., Dub.* *Syrup. Simple Syrup.*

"Take of Sugar [refined] *two pounds and a half;* Water *a pint.* Dissolve the Sugar in the Water by means of a water-bath, and set the solution aside for twenty-four hours; then remove the scum, and if there be any dregs, pour off the clear solution from them." *U.S., Lond.*

"Take of Refined Sugar *fifteen parts;* Water *eight parts.* Dissolve the Sugar in the Water by a gentle heat, and boil a little so as to form a syrup." *Ed.*

"Take of Refined Sugar, finely powdered, *twenty-nine ounces;* Water *a pint.* Add the Sugar gradually to the Water, and digest it with a medium heat [from 100° to 200° F.] in a close vessel till it is dissolved, frequently stirring; afterwards pour off from the dregs if there be any." *Dub.*

This syrup, when properly prepared, is inodorous, of a sweet taste without peculiar flavour, thick, viscid, nearly colourless, and perfectly transparent. If somewhat turbid, as it is apt to be when made with sugar not well refined, it may be clarified by beating the white of an egg to a froth with three or four ounces of water, mixing this with the syrup, boiling the mixture for a short time that the albumen may coagulate, and taking off the scum which rises to the surface, or separating it by filtration through paper or flannel. Two gallons of the syrup may be thus clarified. Any colour and peculiar flavour which it may possess, may be removed by treating it at the same time with a small proportion (about 5 per cent.) of animal charcoal.

Syrup is very useful in the formation of pills and mixtures, and in various other pharmaceutical operations in which sugar in solution is required.

Off. Prep. Confectio Opii, *U.S.*, *Lond.*, *Dub.;* Infusum Acaciæ Catechu, *Ed.;* Syrupus Balsami Tolutani, *Dub.*, *Ed.;* Syrupus Rhei Aromaticus, *U.S.;* Syrupus Zingiberis, *U.S.;* Trochisci Glycyrrhizæ et Opii, *U.S.*, *Ed.* W.

SYRUPUS ACACIÆ. *U.S.* *Syrup of Gum Arabic.*

"Take of Gum Arabic *four ounces;* Sugar [refined] *a pound;* Boiling Water *a pint.* Dissolve the Gum in the water; then add the Sugar, and boil so as to form a syrup." *U.S.*

This is a very convenient addition to pectoral and other mixtures in which the aid of gum Arabic and sugar is required, either to suspend insoluble substances, or to impart demulcent properties. It may be clarified if necessary in the same manner as simple syrup. W.

SYRUPUS ACETI. *U.S.*, *Ed.* *Syrup of Vinegar.*

"Take of Vinegar *a pint;* Sugar [refined] *two pounds.* Dissolve the Sugar in the Vinegar in the manner directed for Syrup." *U.S.*

The *Edinburgh College* takes five parts of vinegar, and seven of refined sugar, and boils them so as to form a syrup.

Syrup of vinegar forms with water a refrigerant and grateful drink in febrile complaints. It may be added to barley water and other farinaceous and mucilaginous beverages and mixtures, when a vegetable acid is not contra-indicated. W.

SYRUPUS ALLII. *U.S.* *Syrup of Garlic.*

"Take of fresh Garlic, sliced, *two ounces;* Distilled Vinegar *a pint;* Sugar [refined] *two pounds.* Macerate the Garlic in the Vinegar, in a glass vessel, for four days; then express the liquor, and set it by that the dregs may subside; lastly, dissolve the Sugar in the clear liquor in the manner directed for Syrup. *U.S.*

This preparation is made upon correct principles, as vinegar is a much better solvent of the active matter of garlic than water; but the proportion of the garlic might be increased with advantage to three times the amount indicated in the formula. The syrup is given in chronic catarrhal affections of the lungs, and is particularly beneficial in infantile cases, by the stimulus which it affords to the nervous system. A teaspoonful may be given for a dose to a child a year old. W.

SYRUPUS ALTHÆÆ. *Lond.*, *Dub.* SYRUPUS ALTHÆÆ OFFICINALIS. *Ed.* *Syrup of Marshmallow.*

"Take of fresh Marshmallow Root, bruised, *half a pound;* Refined Sugar *two pounds;* Water *four pints.* Boil down the Water with the Root to one half, and express the liquor when cool. Set it by for twenty-four hours that the dregs may subside; then pour off the liquor, and having added the Sugar, boil down to the proper consistence." *Lond.*, *Dub.*

The *Edinburgh College* takes one part of the root, ten parts of water, and four parts of sugar, and proceeds as above.

This syrup contains a considerable quantity of starch, besides mucilage, and is very liable to ferment. It is simply demulcent; but is inferior to the mucilage of gum Arabic, and in this country is very seldom prepared. W.

SYRUPUS AURANTII CORTICIS. *U.S.* SYRUPUS AURANTIORUM. *Lond.* SYRUPUS CITRI AURANTII. *Ed.* SYRUPUS AURANTII. *Dub.* *Syrup of Orange Peel.*

"Take of Orange Peel, bruised, *two ounces;* Boiling Water, *a pint;* Sugar [refined] *two pounds and a half.* Macerate the Orange Peel in the Water, in a covered vessel, for twelve hours, and strain; then add the Sugar, and form a syrup with a gentle heat." *U.S.*

The British Colleges direct the fresh peel of Seville oranges. The process of the *London College* agrees with the above, except that three pounds of refined sugar are directed, and its solution effected without heat. The *Edinburgh College* orders three ounces of the peel, a pound and a half of boiling water, and three pounds of refined sugar, proceeding as directed in the U.S. Pharmacopœia. The *Dublin College* employs eight ounces of the peel, six pints of boiling water, and the quantity of sugar indicated in its general directions (page 986); and dissolves the sugar without heat.

In the preparation of this syrup, the solution of the sugar in the infusion of orange peel should be effected with as little heat as possible, in consequence of the volatile nature of the active principle of the peel; and, to facilitate the solution, the sugar should be previously powdered.

The syrup has a pleasant flavour, for which alone it is employed. A fluidounce of the tincture of orange peel added to a pint of simple syrup, affords a preparation little inferior to the officinal, though the presence of the spirit may in some instances be objectionable.

Off. Prep. Confectio Aromatica, *U.S., Ed.;* Confectio Scammonii, *U.S.;* Electuarium Cassiæ, *Dub.* W.

SYRUPUS COLCHICI. *U.S.* SYRUPUS COLCHICI AUTUMNALIS. *Ed.* *Syrup of Meadow-saffron.*

"Take of Vinegar of Meadow-saffron *a pint;* Sugar [refined] *two pounds.* Dissolve the Sugar in the Vinegar of Meadow-saffron in the manner directed for Syrup." *U.S.*

"Take of fresh Meadow-saffron Root, cut into thin slices, *an ounce;* Vinegar *sixteen ounces;* Refined Sugar *twenty-six ounces.* Macerate the Root in the Vinegar for two days, occasionally shaking the vessel; then strain with gentle expression, and having added the Sugar, boil a little so as to form a syrup." *Ed.*

This preparation is much inferior to the wine of colchicum, and is very seldom used. The dose is from a fluidrachm to half a fluidounce, or more. W.

SYRUPUS CROCI. *Lond.* *Syrup of Saffron.*

"Take of saffron *an ounce;* Boiling Water *a pint;* Refined Sugar *two pounds and a half.* Macerate the Saffron in the Water for twelve hours, in a lightly covered vessel; then strain the Liquor, and add the Sugar." *Lond.*

This is slightly stimulant, but is valued chiefly for its fine colour.

SYRUPUS DIANTHI CARYOPHYLLI. *Ed.* *Syrup of the Clove Pink.*

"Take of the fresh Petals of the Clove Pink, freed from their claws, *one* *part;* Boiling Water *four parts;* Refined Sugar *seven parts.* Macerate the Petals in the Water for twelve hours; then add the Sugar to the filtered liquor, and dissolve it with a gentle heat so as to form a syrup." *Ed.*

The only value of this preparation consists in its beautiful red colour, and agreeable flavour. A syrup closely resembling it in these respects, is sometimes prepared from an infusion of cloves and sugar, with the addition of a little cochineal. The genuine syrup may be distinguished by the effect of alkalies, which change its colour to green, while they only vary the shade of red in the counterfeit. Neither of them is much used in this country. W.

SYRUPUS LIMONIS. *U.S., Dub.* SYRUPUS LIMONUM. *Lond.* SYRUPUS CITRI MEDICÆ. *Ed.* *Lemon Syrup.*

"Take of Juice of Lemons, strained, *a pint;* Sugar [refined] *two pounds.* Dissolve the Sugar in the Juice in the manner directed for Syrup." *U.S. Lond.*

"Take of Juice of Lemons, strained after the dregs have subsided, *three parts*; Refined Sugar *five parts.* Dissolve the Sugar," *Ed.*

"Take of Juice of fresh Lemons *two pints.* As soon as the dregs have subsided, put the Juice into a matrass, and subject it for fifteen minutes to the heat of boiling water. When cold, strain it through a sieve, and form a syrup." *Dub.*

This syrup forms a cooling and grateful addition to beverages in febrile complaints, and serves to conceal the taste of saline purgatives given in solution. W.

SYRUPUS MORI. *Lond.* *Syrup of Mulberries.*

"Take of Mulberry Juice, strained, *a pint;* Refined Sugar *two pounds.* Dissolve the Sugar in the Mulberry Juice in the manner directed for Simple Syrup." *Lond.*

This may be used for the same purposes with lemon syrup. In like manner syrups may be prepared from various succulent fruits, such as *strawberries, raspberries, pineapples,* &c. When the juice is thick, it may be diluted with from one-third of its bulk to an equal bulk of water, previously to the addition of the sugar. In the preparation of *raspberry syrup*, which, as ordinarily made, is apt to gelatinize, M. Blondeau recommends that the strained juice be allowed to stand from eight to fifteen hours, according to the temperature, in order to ferment. The juice separates into two portions, the upper thick, the lower clear. The latter is to be separated by straining and made into a syrup with the usual proportion of sugar. These syrups are employed to flavour drinks, and are much used as grateful additions to carbonic acid water. W.

SYRUPUS PAPAVERIS. *Lond.* SYRUPUS PAPAVERIS SOMNIFERI. *Ed., Dub.* *Syrup of Poppies.*

"Take of the dried Capsules of the White Poppy, bruised and freed from the seeds, *fourteen ounces;* Refined Sugar *two pounds;* Boiling Water *two gallons and a half.* Macerate the Capsules in the Water for twenty-four hours; then by means of a water-bath, boil down to a gallon, and express strongly. Boil down the strained liquor again to two pints, and strain it while hot. Set it by for twelve hours that the dregs may subside, then boil down the clear liquor to a pint, and add the sugar in the manner directed for Simple Syrup." *Lond.*

"Take of the Capsules of the White Poppy, dried and freed from their seeds, *one part;* Boiling Water *fifteen parts;* Refined Sugar *two parts.* Macerate the sliced Capsules in the water for twelve hours; then boil till only one-third of the liqour remains, and strain the decoction with strong expression. Boil the strained liquor to one-half, and again strain; lastly, add the Sugar and boil a little so as to form a syrup." *Ed.*

"Take of the Capsules of the White Poppy, dried, deprived of their seeds, and bruised, *seventeen ounces*; Boiling Water *two gallons*. Macerate the Capsules in the Water for twenty-four hours; then, by means of a water-bath, boil down to a gallon, and strongly express. Boil down the strained liquor again to two pints, and strain it while hot. Set it by for twelve hours that the dregs may subside; then boil down the clear liquor to a pint, and form a syrup." *Dub.*

The use of the water-bath in preparing this syrup, as directed by the London and Dublin Colleges, is superfluous, and delays the process. As the capsules contain variable proportions of the narcotic principle, the syrup prepared from them is necessarily of variable strength. It is, moreover, very apt to spoil. Its place might with great propriety, be supplied by a syrup prepared from one of the salts of morphia, which would keep well and have the advantage of uniform strength. Four grains of the sulphate of morphia dissolved in a pint of syrup, would afford a preparation at least equal to the average strength of the syrup of poppies, and much more certain in its operation.

The syrup of poppies is employed, chiefly in infantile cases, to allay cough, quiet restlessness, relieve pain, and promote sleep. The dose is from half a fluidrachm to a fluidrachm for an infant, from half a fluidounce to a fluidounce for an adult. W.

SYRUPUS RHAMNI. *Lond., Dub.* *Syrup of Buckthorn.*

"Take of the fresh Juice of Buckthorn Berries *four pints;* Ginger Root, sliced, Pimento Berries, in powder, each, *half an ounce;* Refined Sugar *three pounds and a half.* Set by the Juice for three days that the dregs may subside, and then strain it. To a pint of the clear Juice add the Ginger and Pimento; then macerate for four hours with a gentle heat, and strain. Boil down the remainder of the Juice to a pint and a half; mix the liquors, and add the Sugar in the manner directed for Simple Syrup." *Lond.*

Take of the fresh Juice of Buckthorn Berries *two pints and a half;* Ginger Root, sliced, Pimento Berries, in powder, each, *three drachms.* Set by the Juice that the dregs may subside, and then strain it. Add the Ginger and Pimento to ten ounces of the clear Juice, macerate for twenty-four hours, and filter. Boil down the remaining Juice to a pint, mix the liquors, and form a syrup." *Dub.*

The syrup of buckthorn is a brisk cathartic, but having an unpleasant taste, and being apt to gripe violently, is very seldom employed. The dose is from half a fluidounce to a fluidounce. The patient should drink freely of thin gruel or other demulcent beverage during its operation. W.

SYRUPUS RHEI. *U.S.* *Syrup of Rhubarb.*

"Take of Rhubarb, bruised, *two ounces;* Boiling Water *a pint;* Sugar [refined] *two pounds.* Macerate the Rhubarb in the Water for twenty-four hours, and strain; then add the Sugar, and boil for a short time so as to form a syrup." *U.S.*

This is a mild cathartic, adapted to the cases of infants, to whom it may be given in the dose of one or two fluidrachms.

It has been proposed to form the *syrup* of rhubarb in the manner directed in the U.S. Pharmacopœia for the *aromatic syrup*, by first preparing a tincture with diluted alcohol, then evaporating the spirituous portion by means of a water-bath, and incorporating the remainder with sugar. It is questionable, however, whether this would be an improvement on the officinal formula; as, though a stronger syrup might be obtained, there would be some risk that a portion of the alcohol might remain, and render the preparation too stimulating to meet the indication for which it was originally intended. W.

SYRUPUS RHEI AROMATICUS *U.S.* *Aromatic Syrup of Rhubarb.*

"Take of Rhubarb, bruised, *two ounces and a half;* Cloves, bruised, Cinnamon, bruised, each, *half an ounce;* Nutmeg, bruised, *two drachms;* Diluted Alcohol *two pints;* Syrup *six pints.* Macerate the Rhubarb and aromatics in the Diluted Alcohol for fourteen days, and strain; then, by means of a water-bath, evaporate the liquor to a pint, and while it is still hot, mix it with the syrup previously heated." *U.S.*

This process is a decided improvement upon that of the first edition of the U.S. Pharmacopœia, in which the rhubarb and spices were boiled long in water, and sugar and alcohol afterwards added to the strained decoction. The oils of the aromatics were thus driven off and wasted, water being able to take up but a small proportion; while the preparation was rendered too stimulant by the spirituous addition. By the present process the alcohol employed in the maceration, after having performed its office of extracting the virtues of the medicines, is evaporated at a temperature insufficient for the volatilization of the oils, and a syrup is obtained at least as strong as that of the old Pharmacopœia, with less waste of materials, and without the objectionable presence of a large proportion of spirit.

As the original formula had been in general use, and practitioners were accustomed to the preparation, it was thought advisable that the present should have as nearly as possible the same strength; otherwise the proportion both of rhubarb and of spices might have been with geat propriety augmented. The apothecary should be careful to employ aromatics of the best quality, and to effect the evaporation of the tincture, according to the officinal direction, by means of a water-bath.

The aromatic syrup of rhubarb is a warm stomachic laxative, too feeble for adult cases, but well calculated for the bowel complaints of infants, which are so frequent in our cities during the summer season, and as a remedy for which the preparation has been long in use under the name of *spiced syrup of rhubarb.* The dose for an infant with diarrhœa is a fluidrachm, repeated every two hours till the passages indicate by their colour that the medicine has operated. W.

SYRUPUS RHEI ET SENNÆ. *U.S.* *Syrup of Rhubarb and Senna.*

"Take of Rhubarb, bruised, Senna, each, *an ounce and a half;* Cardamom, bruised, *three drachms;* Boiling Water *a pint;* Sugar *two pounds.* Macerate the Rhubarb, Senna, and Cardamom in the Water, in a covered vessel, for twenty-four hours, and strain; then add the Sugar, and boil for a short time so as to form a syrup." *U.S.*

In the process of the former edition of the U. S. Pharmacopœia, the infusion was injudiciously boiled down to one-half before the addition of the sugar, so that the virtues of the senna were necessarily impaired, while the oil of the cardamom was in great measure driven off. In the present process this error is avoided. The syrup of rhubarb and senna is more active than the simple syrup of rhubarb, and may be used as a gentle tonic cathartic in the complaints both of children and adults. The dose for the former is a fluidrachm, for the latter, a fluidounce. W.

SYRUPUS RHŒADOS. *Lond.* SYRUPUS PAPAVERIS RHŒADIS. *Dub.* *Syrup of Red Poppy.*

"Take of the fresh Petals of the Red Poppy *a pound;* Boiling Water *a pint and two fluidounces;* Refined Sugar *two pounds and a half.* To the Water heated by a water-bath, gradually add the Petals, occasionally stirring; then, having removed the vessel, macerate for twelve hours; express the liquor, and set it by that the dregs may subside; lastly, add the Sugar in the manner directed for Simple Syrup." *Lond.*

"Take of the fresh Petals of the Red Poppy *a pound;* Boiling Water *twenty fluidounces.* Add the Petals gradually to the boiling water; then, having removed the vessel from the fire, macerate with an inferior heat [between 90° and 100°] for twelve hours; express the liquor, and set it by that the dregs may subside; lastly, add the Sugar, and form a syrup." *Dub.*

The object of introducing the petals into water heated by a water-bath, is that they may shrink by being scalded, as otherwise they could not be completely immersed in the quantity of water directed. After this has been accomplished, they should be immediately removed from the fire, lest the liquor should become too thick and ropy. The fine red colour of this syrup is its only recommendation. It has no medical virtues, and is very liable to ferment. W.

SYRUPUS ROSÆ. *Lond., Dub.* SYRUPUS ROSÆ CENTIFOLIÆ. *Ed.* *Syrup of Roses.*

"Take of the dried Petals of the Hundred-leaved rose *seven ounces;* Refined Sugar *six pounds;* Boiling Water *four pints.* Macerate the Petals in the water for twelve hours and strain. Evaporate the strained liquor, by means of a water-bath, to two pints and a half; then add the Sugar in the manner directed for Simple Syrup." *Lond., Dub.*

"Take of the fresh Petals of the Hundred-leaved Rose, *one part;* Boiling Water *four parts;* Refined Sugar *three parts.* Macerate the Petals in the Water for twelve hours; then add the Sugar to the strained liquor, and boil so as to form a syrup." *Ed.*

This syrup is gently laxative, and, on account of its mildness, may be given with advantage to infants and persons of delicate habit. It is without the fragrance of the rose; but has a reddish colour which is rendered bright red by acids, and green or yellow by alkalies. The dose is from two fluidrachms to one or two fluidounces. W.

SYRUPUS ROSÆ GALLICÆ. *Ed.* *Syrup of Red Roses.*

"Take of the dried Petals of the Red Rose *one part;* Refined Sugar *two parts;* Boiling Water *nine parts.* Macerate the Petals in the Water for twelve hours; then boil a little and strain. Add the Sugar to the strained liquor, and again boil a little, so as to form a Syrup." *Ed.*

The syrup of red roses is mildly astringent; but is valued more for its fine red colour, on account of which it is occasionally added to mixtures.

Off. Prep. Electuarium Catechu Compositum, *Ed.* W.

SYRUPUS SARSAPARILLÆ. *U.S., Lond., Dub.* *Syrup of Sarsaparilla.*

"Take of Sarsaparilla, bruised, *two pounds;* Guaiacum Wood, rasped, *three ounces;* Red Roses, Senna, Liquorice Root, bruised, each, *two ounces;* Oil of Sassafras, Oil of Anise, each, *five minims;* Oil of Partridge-berry *three minims;* Sugar [refined] *eight pounds;* Diluted Alcohol *ten pints.* Macerate the Sarsaparilla, Guaiacum Wood, Roses, Senna, and Liquorice Root, in the Diluted Alcohol, for fourteen days; then express and filter through paper. Evaporate the tincture, by means of a water-bath, to four pints and a half; then add the Sugar, and dissolve it so as to form a syrup. With this when cold mix the oils previously triturated with a small quantity of the syrup. *U.S.*

The *London College* prepares the syrup of sarsaparilla by macerating a pound of the sliced root in a gallon of boiling water for twenty-four hours, then boiling down to four pints, straining the liquor while hot, adding a pound of refined sugar, and evaporating to the proper consistence.

The *Dublin College* obtains in the same manner four pints of a concentrated strained decoction, and prepares a syrup with this according to their general directions. (See page 986.)

The syrup of the London and Dublin Colleges is necessarily a very weak if not inert preparation, the virtues of the sarsaparilla being injured or destroyed by the long boiling. That of the U. S. Pharmacopœia is prepared on more correct principles, and is a great improvement upon the syrup of the former edition, which was intended to represent the famous French *sirop de Cuisinier*. The Pharmacopœia of 1820 directed the sarsaparilla to be exhausted by long continued decoction in water, and was indefinite as to the degree of concentration. Now it has been proved that diluted alcohol more thoroughly extracts the acrid principles of the root, upon which its activity probably depends, than water, and that these principles are either dissipated or destroyed by the long continued application of a boiling heat.* In the present formula, therefore, which employs diluted alcohol as the menstruum, the root is more completely exhausted of its active matter, while the heat applied to the concentration, being no higher than is requisite for the evaporation of the alcohol, is insufficient to injure the preparation. The spirituous menstruum has, moreover, the advantage of not dissolving the inert fecula, which encumbers the syrup prepared by decoction and renders it liable to spoil. The operator should be careful to comply exactly with the directions of the Pharmacopœia in relation to the period of maceration and the use of the water-bath. The essential oils being intended solely to communicate a pleasant flavour, are used in very small proportion. Perhaps the pale or hundred-leaved roses might be substituted with propriety for the red; as, being slightly laxative, they accord better with the character of the preparation, and are, besides, more easily procured of good quality. We are confident that a syrup prepared according to the officinal process will be found to possess the virtues of sarsaparilla in a high degree; but the practitioner should be aware that much of the root as it exists in the market is nearly or quite inert, and should be prepared to meet with disappointment in the use of this or any other preparation, unless satisfied of the good quality of the drug from which it is made.

The dose of the syrup of sarsaparilla is half a fluidounce, equivalent to somewhat less than a drachm of the root, to be taken three or four times a day. W.

SYRUPUS SCILLÆ. *U.S.* SYRUPUS SCILLÆ MARITIMÆ. *Ed.* *Syrup of Squill.*

"Take of Vinegar of Squill *a pint;* Sugar [refined] *two pounds.* Dissolve the Sugar in the Vinegar of Squill in the manner directed for Syrup." *U.S.*

The *Edinburgh College* takes four parts of the vinegar of squill and seven parts of refined sugar, in powder, and dissolves the sugar with a gentle heat so as to form a syrup.

---

* See a paper by J. Hancock, M. D., republished in the *Journ. of the Phil. Col. of Pharm.* i. 295; a communication by M. Beral to the *Journal de Pharmacie*, xv. 657; and another by M. Soubeiran in the same Journal, xvi. 38.

This syrup is much employed as an expectorant, especially in combination with a solution of tartarized antimony. The dose is about a fluidrachm. In infantile cases of catarrh and other pectoral complaints, it is sometimes given, in the same dose, as an emetic. W.

SYRUPUS SENEGÆ. *U. S.* *Syrup of Seneka.*

"Take of Seneka, bruised, *four ounces;* Water *a pint;* Sugar [refined] *a pound.* Boil the Water with the Seneka to one-half, and strain; then add the Sugar, and boil so as to form a syrup." *U.S.*

The quantity of seneka is perhaps greater than the water is capable of exhausting; but an active preparation is ensured. The syrup may be given as a stimulant expectorant in the dose of one or two fluidrachms. W.

SYRUPUS SENNÆ. *Lond.* SYRUPUS CASSIÆ SENNÆ. *Ed.* *Syrup of Senna.*

"Take of Senna Leaves *two ounces;* Fennel Seeds, bruised, *an ounce;* Manna *three ounces;* Refined Sugar *a pound;* Boiling Water *a pint.* Macerate the Senna Leaves and Fennel Seeds in the Water with a gentle heat for an hour. Strain the liquor and mix with it the Manna and Sugar; then boil down to the proper consistence." *Lond.*

"Take of Senna Leaves *two ounces;* Boiling Water *a pound and a half;* Molasses *eight ounces.* Macerate the Leaves in the Water in a slightly covered vessel for four hours, and strain; then add the Molasses, and boil with a gentle heat to the consistence of a syrup." *Ed.*

The London syrup is preferable to the Edinburgh in consequence of the aromatic ingredient, though the manna which it contains is apt to crystallize. The preparation is intended chiefly as a cathartic for children, to whom it may be given in the dose of one or two fluidrachms. We prefer the Syrupus Rhei et Sennæ of the U.S. Pharmacopœia. W.

SYRUPUS TOLUTANUS. *Lond.* SYRUPUS TOLUIFERÆ BALSAMI. *Ed.* SYRUPUS BALSAMI TOLUTANI. *Dub.* *Syrup of Tolu.*

"Take of Balsam of Tolu *an ounce;* Boiling Water *a pint;* Refined Sugar *two pounds.* Boil the Balsam in the Water for half an hour, in a covered vessel, occasionally stirring, and strain the liquor when cold; then add the Sugar in the manner directed for Simple Syrup." *Lond.*

The *Edinburgh College* prepares this syrup by adding gradually one ounce of the tincture of balsam of tolu to two pounds of simple syrup just prepared, and before it has become cold after removal from the fire. The *Dublin College* pursues the same plan, using an ounce of the tincture to a pint and a half of syrup.

The London process affords a syrup with a finer flavour than that prepared with the tincture. The same portion of balsam is, according to Mr. Brande, usually employed in successive operations, and it long continues to impart odour and taste to boiling water. The syrup of tolu is wholly inert as a medicine, and is employed only to communicate its pleasant flavour to mixtures. W.

SYRUPUS VIOLÆ. *Dub.* SYRUPUS VIOLÆ ODORATÆ. *Ed.* *Syrup of Violets.*

"Take of the fresh Petals of the Violet *two pounds;* Boiling Water *five pints.* Macerate for twenty-four hours; then filter the liquor through fine linen, without expression; lastly, add the Sugar [twenty-nine ounces for every pint of liquor] and form a syrup." *Dub.*

"Take of fresh Violets *two parts;* Boiling Water *eight parts;* Refined Sugar *fifteen parts.* Macerate the Violets in the Water for twenty-four hours, in a covered glass or glazed earthenware vessel, then strain without expression, and add the Sugar." *Ed.*

This syrup has a deep blue colour and an agreeable flavour. It is said that its colour is most beautiful when it is prepared in well cleaned pewter vessels; but the action of the metal has not been satisfactorily explained. As it is apt to fade by time, it is sometimes counterfeited with materials the colour of which is more permanent. The fraud may usually be detected by the addition of an acid or alkali, the former of which reddens the syrup of violets, the latter renders it green, while they produce no such change upon the counterfeit.

The syrup acts as a gentle laxative when given to infants in the dose of one or two fluidrachms; but it is used chiefly as a test of acids and alkalies. For the latter purpose, a syrup prepared from the juice of the red cabbage may be substituted in its place. It is very seldom kept in our shops. W.

SYRUPUS ZINGIBERIS. *U. S., Lond., Dub.* SYRUPUS AMOMI ZINGIBERIS. *Ed.* *Syrup of Ginger.*

"Take of Tincture of Ginger *two fluidounces;* Syrup *a gallon.* Mix the Tincture with the Syrup, and by means of a water-bath evaporate the alcohol." *U. S.*

The *London College* macerates two ounces of sliced ginger, for four hours, in a pint of boiling water, and having strained the infusion, adds two pounds of refined sugar in the manner directed for simple syrup. The *Edinburgh College* macerates four ounces of bruised ginger, for twenty-four hours, in a pound of boiling water, strains, adds twenty-two ounces of refined sugar, and dissolves it with a gentle heat. The *Dublin College* macerates four ounces of the bruised root, for twenty-four hours, in three pints of boiling water, filters the liquor, and adds twenty-nine ounces of refined sugar to each pint.

The process of the U.S. Pharmacopœia is the most easy, and affords a syrup in every respect equal to the others, without being like them encumbered with the mucilage and starch of the root. In order that it may be of the proper strength, it is necessary that the tincture should have been made with the best Jamaica ginger.

The syrup of ginger is much used as a warm stomachic addition to tonic and purgative infusions or mixtures, and to impart flavour to drinks, particularly to carbonic acid water.

Off. Prep. Electuarium Catechu Compositum, *Dub;* Electuarium Opiatum, *Ed.* W.

* * *

TINCTURÆ.

Tinctures.

Tinctures, in the pharmaceutical sense of the term, are solutions of medicinal substances in alcohol or diluted alcohol, prepared by maceration or digestion. Solutions in ammoniated alcohol and ethereal spirit are embraced under the same denomination, but are severally distinguished by the addition of an epithet expressive of their peculiar character. The advantages of alcohol as a menstruum are, that it dissolves principles which are sparingly or not at all soluble in water, and contributes to their preservation when dissolved. In no instance, however, is pure absolute alcohol employed. The United States, London, and Edinburgh Pharmacopœias, direct it of the sp. gr. 0.835, that of Dublin, of the sp. gr. 0.840. When of these densities it contains a considerable proportion of water, and is capable of dissolving more or less of substances which are insoluble in anhydrous alcohol, while its solvent power, in relation to bodies soluble in this fluid, is sufficient for all practical purposes. In numerous instances, diluted alcohol or proof spirit is preferable to alcohol itself; as it is capable of extracting a larger proportion of those active principles of plants which require an aqueous menstruum, at the same time that it is strong enough to prevent spontaneous decomposition, and has the advantages of being cheaper and less stimulating. The diluted alcohol of the different Pharmacopœias is not of the same strength, that of the United States and Edinburgh consisting of equal measures of officinal alcohol and water, and having the sp. gr. 0.935, while that of London has the sp. gr. 0.930, and that of Dublin 0.919. The difference, however, is not very material. Alcohol or rectified spirit is preferred as the solvent, when the substance to be extracted or dissolved is nearly or quite insoluble in water, as in the instances of the resins, guaiac, camphor, and the essential oils. The presence of water is here injurious, not only by diluting the menstruum, but by exercising an affinity for the alcohol which interferes with its solvent power. Thus water added to an alcoholic solution of one of these bodies, produces a precipitate by abstracting the alcohol from it. Diluted alcohol or proof spirit is employed, when the substance is soluble both in alcohol and water, or when one or more of the ingredients are soluble in the one fluid, and one or more in the other, as in the case of those vegetables which contain extractive or tannin, or the native salts of the organic alkalies, or gum united with resin or essential oil. As these include the greater number of medicines from which tinctures are prepared, diluted alcohol is most frequently used.

In the preparation of the tinctures, the medicine should be in the dry state, and properly comminuted by being bruised, sliced, or pulverized. It is usually better in the condition of a coarse than of a very fine powder; as in the latter it is apt to agglutinate, and thus present an impediment to the penetration of the menstruum. When several substances differing in solubility are employed, they should be added successively to the spirit, those least soluble first, those most so last; as otherwise the menstruum might become saturated with the ingredient for which it has the strongest affinity, and thus be rendered incapable of dissolving a due proportion of the others.

The Edinburgh College prepares tinctures by digestion with a heat from 90° to 100°, continued usually for seven days. Our own Pharmacopœia follows that of London, in directing maceration at ordinary temperatures, and extending the period to two weeks. The latter plan is preferable, as it is most convenient, and equally effectual, the lower temperature being compensated by the longer maceration. When circumstances require that the tincture should be speedily prepared, digestion may be resorted to. Care should always be taken to keep the vessel well stopped, in order to prevent the evaporation of the alcohol. The materials should be frequently shaken during the digestion or maceration; and this caution is especially necessary when the substance acted on is in the state of powder. The tincture should not be used till the maceration is completed, when it should be separated from the dregs either by simply filtering it through paper, or, when force is requisite, by first expressing it through linen, and subsequently filtering. Tinctures should be kept in bottles accurately stopped, in order to prevent evaporation, which might, in some instances, be attended with serious inconvenience, by increasing their strength beyond the officinal standard.

Medicines are most conveniently administered in tincture, which act powerfully in small doses, as the proportion of alcohol in which they are dissolved is too minute to produce an appreciable effect. Those which require to be given in large doses, should be cautiously employed in this form, lest the injury done by the menstruum should more than counterbalance their beneficial operation. This remark is particularly applicable to chronic cases of disease, in which the use of tinctures is apt to result in the establishment of fatal habits of intemperance. The tinctures of the weaker medicines are more frequently given as adjuvants of other remedies, than with the view of obtaining their own full effect upon the system.

The following general direction is given in the U.S. Pharmacopœia. "The Tinctures should be prepared in stopped glass bottles, and should be often shaken during the maceration." An equivalent direction is given by the British Colleges. W.

TINCTURA ALOES. *U.S., Lond., Dub.* TINCTURA ALOES SOCOTORINÆ. *Ed.* *Tincture of Aloes.*

"Take of Aloes, in powder, *an ounce;* Liquorice [extract] *three ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

The British Colleges take half an ounce of Socotrine aloes, in powder, and an ounce and a half of liquorice. The *London College* macerates these with four fluidounces of rectified spirit and a pint of water for fourteen days; the *Edinburgh College* digests them with four ounces of stronger alcohol (alcohol, *U.S.*) and a pound of water for seven days; and the *Dublin College*, having previously dissolved the liquorice in eight ounces of boiling water, and added eight fluidounces of proof spirit, digests the whole for seven days.

The tincture of the U.S. Pharmacopœia differs from those of the British Colleges in being prepared with a stronger spirit, and is therefore more stimulating. The latter are little more than infusions, with the addition of sufficient alcohol to prevent spontaneous decomposition. The liquorice is added to cover the taste of the aloes; but it answers the end imperfectly; and the preparation, on account of its unpleasant bitterness, is little used, aloes being generally administered in the form of pill. The dose is from half a fluidounce to a fluidounce and a half. W.

TINCTURA ALOES ÆTHEREA. *Ed.* *Ethereal Tincture of Aloes.*

"Take of Socotrine Aloes, Myrrh, each, in powder, *an ounce and a half;* Saffron, cut, *an ounce;* Sulphuric Ether with Alcohol [Spirit of Sulphuric Ether] *a pound.* Digest the Myrrh with the Ether for four days; then add the Saffron and Aloes. Digest again for four days, and when the dregs have subsided, pour off the tincture," *Ed.*

This tincture differs from the following chiefly in consequence of the ether which it contains, and which may be found serviceable when spasm, or other irregular nervous action, accompanies the symptoms which call for the combined use of myrrh and aloes. It is very seldom employed in this country. The dose is one or two fluidrachms. W.

TINCTURA ALOES ET MYRRHÆ. *U.S., Ed.* TINCTURA ALOES COMPOSITA. *Lond. Dub.* *Tincture of Aloes and Myrrh.*

"Take of Aloes, in powder, Saffron, each, *three ounces;* Tincture of

Myrrh *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

The process of the *London College* differs from the above only in the specification of Socotrine aloes. The *Dublin College* omits the saffron, but in other respects gives the same directions. The *Edinburgh College* takes two ounces of myrrh, a pound and a half of alcohol, and half a pound of water; digests for four days; then adds an ounce and a half of Socotrine aloes and an ounce of saffron; digests again for three days; and finally pours off the tincture from the sediment.

This tincture is a modification of the *elixir proprietatis* of Paracelsus. The saffron, which has been retained in compliance with former prejudices, can add little to the efficacy of the preparation; and, being very expensive, might with great propriety be much reduced. It serves, however, to impart a richness to the tincture, the want of which might he considered a defect by those accustomed to its use.

The tincture is purgative, tonic, and emmenagogue; and is considerably employed in chlorosis, and other disordered states of health in females, connected with suppressed, retained, or deficient menstruation ,and with a constipated state of bowels. It may also be used as a stomachic laxative in cold, languid habits, independently of menstrual disorder. The dose is from one to two fluidrachms. W.

TINCTURA ANGUSTURÆ. *U.S., Dub.* TINCTURA BONPLANDIÆ TRIFOLIATÆ. *Ed.* *Tincture of Angustura Bark.*

"Take of Angustura Bark, bruised, *two ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U. S.*

The *Dublin* process corresponds with the above, the bark being directed in coarse powder. The *Edinburgh College* takes two ounces of the bark in coarse powder, and two pounds and a half of diluted alcohol, and digests for a week.

This tincture contains the active principles of Angustura bark, and may be given in the dose of one or two fluidrachms. W.

TINCTURA ASSAFŒTIDÆ. *U.S., Lond.* TINCTURA FERULÆ ASSÆFŒTIDÆ. *Ed.* TINCTURA ASSÆFŒTIDÆ. *Dub.* *Tincture of Assafetida.*

"Take of Assafetida *four ounces;* Alcohol [Rectified Spirit, *Lond.*] *two pints.* Macerate for fourteen days, and filter through paper." *U.S., Lond.*

The *Edinburgh College* takes four ounces of assafetida, and two pounds and a half of alcohol, and digests for a week. The *Dublin* process differs from that of the U.S. Pharmacopœia only in triturating the assafetida with half a pint of water previously to the addition of the alcohol.

This tincture becomes milky on the addition of water, in consequence of the separation of the resin. It possesses all the virtues of assafetida. The medium dose is a fluidrachm.

Off. Prep. Enema Fœtidum, *Dub.* W.

TINCTURA AURANTII. *Lond.* *Tincture of Orange Peel.*

"Take of fresh Orange Peel *three ounces;* Proof Spirit *two pints.* Macerate for fourteen days, and filter." *Lond.*

It is the peel of the Seville orange which is intended by the London College; and the outer part only should be used, the inner whitish portion being inert. Brande says that the tincture may be prepared, without disadvantage, from the dried peel, of which two ounces are equal to three of the fresh. The tincture of orange peel is employed as a grateful addition to infusions, decoctions, and mixtures. It was omitted by mistake in the last edition of the Dublin Pharmacopœia, as it is an ingredient in one of the officinal preparations of that work.

Off. Prep. Mistura Ferri Aromatica, *Dub.* W.

TINCTURA BENZOINI COMPOSITA. *U.S., Lond., Ed.* TINCTURA BENZOES COMPOSITA. *Dub.* *Compound Tincture of Benzoin.*

"Take of Benzoin *three ounces;* Purified Storax *two ounces;* Tolu [balsam] *an ounce;* Aloes, in powder, *half an ounce;* Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

The processes of the British Colleges do not materially differ from the above, which was taken originally from the *London* Pharmacopœia. The *Edinburgh* and *Dublin Colleges* direct a digestion of seven days; and the former employs an additional ounce of the balsam of tolu instead of the two ounces of purified storax.

This tincture is a stimulating expectorant, occasionally used in chrônic catarrhal affections, but more frequently as a local application to indolent ulcers. It is the *balsamum traumaticum* of the older Pharmacopœias, and may be considered as a simplified form of certain complex compositions, such as *baume de commandeur, Wade's balsam, Friars' balsam, Jesuits' drops, &c.*, which were formerly in repute, and are still esteemed among the vulgar as pectorals and vulneraries. *Turlington's balsam,* which is a popular remedy in this country for such purposes, consists, as usually prepared in Philadelphia, of the ingredients of the officinal tincture, with the addition of Peruvian balsam, myrrh, and angelica root.* It is scarcely necessary to state, that the application of these remedies to fresh wounds must frequently prove injurious, by inducing too much inflammation, and thus preventing union by the first intention. The compound tincture of benzoin is decomposed by water. The dose is from thirty minims to two fluidrachms. W.

TINCTURA BUCHU. *Dub.* *Tincture of Buchu Leaves.*

"Take of the Leaves of the Diosma crenata *two ounces;* Proof Spirit *a pint.* Macerate for seven days, and filter." *Dub.*

This tincture has the virtues of buchu leaves, and may be given in the dose of from one to four fluidrachms, either simply diluted with water, or as an addition to the infusion of the leaves. W.

TINCTURA CAMPHORÆ. *U.S., Ed.* SPIRITUS CAMPHORÆ. *Lond.* TINCTURA CAMPHORÆ sive SPIRITUS CAMPHORATUS. *Dub.* *Tincture of Camphor.*

"Take of Camphor *four ounces;* Alcohol *two pints.* Dissolve the Camphor in the Alcohol." *U.S.*

The *London* and *Dublin* preparations are the same with ours. The *Edinburgh College* directs an ounce of camphor to a pound of alcohol; and allows the tincture to be prepared with a double or triple proportion of camphor.

This is used chiefly as an anodyne embrocation in rheumatic and gouty pains, chilblains, and the inflammation resulting from sprains and bruises. It may also be employed internally; due regard being paid to the stimulant

---

*The following is the formula for *Turlington's balsam* adopted by the Philadelphia College of Pharmacy. "Take of Alcohol Oviij., Benzoin ℥xij., Liquid Storax ℥iv., Socotrine Aloes ℥j., Peruvian Balsam ℥ij., Myrrh ℥j., Angelica root ℥ss., Balsam of Tolu ℥iv., Extract of Liquorice root ℥iv. Digest for ten days and strain." *Journ. of the Phil. Col. of Pharm.* v. 28.

properties of the alcohol. The camphor is precipitated by the addition of water, but may be suspended by the intervention of sugar. The dose is from five drops to a fluidrachm, first poured upon sugar, and then mixed with water. W.

TINCTURA CANTHARIDIS. *U.S., Lond., Dub.* TINCTURA CANTHARIDIS VESICATORIÆ. *Ed.* *Tincture of Spanish Flies.*

"Take of Spanish Flies, bruised, *three drachms;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S. Lond.*

The *Edinburgh College* orders a drachm of the flies and a pound of diluted alcohol; the *Dublin College,* two drachms of the former and a pint and a half of the latter; and both digest for a week.

This tincture is one of the most convenient forms for the internal use of Spanish flies, the virtues of which it possesses to their full extent. (See *Cantharis.*) It is occasionally employed externally as a rubefacient; but its liability to vesicate should be taken into consideration. The dose is from twenty drops to a fluidrachm, repeated three or four times a day. W.

TINCTURA CAPSICI. *U.S., Lond., Dub.* *Tincture of Cayenne Pepper.*

"Take of Cayenne Pepper *an ounce;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S., Lond., Dub.*

This form of capsicum is a useful stimulant in very low states of the system with great gastric insensibility, as in malignant, scarlet, and typhus fevers, and in the cases of drunkards. It may also be used as a gargle, diluted with rose water or some mucilaginous fluid. (See *Capsicum.*) Applied by means of a camel's hair pencil to the relaxed uvula, it sometimes produces contraction, and relieves prolapsus of that part. The dose is one or two fluidrachms. W.

TINCTURA CARDAMOMI. *U.S., Lond.* TINCTURA AMOMI REPENTIS. *Ed.* *Tincture of Cardamom.*

"Take of Cardamom, bruised, *four ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

The process of the *Edinburgh College* agrees with the above, except that two pounds and a half of diluted alcohol are used instead of two pints, and digestion for a week instead of maceration for two weeks. The *London College* takes three ounces of the bruised seeds and two pints of proof spirit, and macerates for fourteen days.

This tincture is an agreeable aromatic, and may be advantageously added to tonic and purgative infusions. W.

TINCTURA CARDAMOMI COMPOSITA. *Lond., Dub.* *Compound Tincture of Cardamom.*

"Take of Cardamom Seeds, Caraway Seeds, Cochineal, each bruised, *two drachms;* Cinnamon Bark, bruised, *half an ounce;* Raisins, stoned, *four ounces;* Proof Spirit *two pints.* Macerate for fourteen days, and filter." *Lond.*

The *Dublin College* gives the same formula, omitting the cochineal and raisins, and directing the cardamom seeds freed from their husks.

This is a very agreeable aromatic tincture, occasionally used as a carminative, in the dose of one or two fluidrachms, but more frequently as an addition to mixtures, infusions, &c., which it renders pleasant to the taste, and acceptable to the stomach. W.

TINCTURA CASCARILLÆ. *Lond., Dub.* TINCTURA CROTONIS ELEUTHERIÆ. *Ed.* *Tincture of Cascarilla.*

"Take of Cascarilla Bark, in powder, *four ounces*; Proof Spirit *two pints.* Macerate for fourteen days, and filter." *Lond.*

The *Edinburgh College* employs four ounces of the bruised bark, and two pounds and a half of diluted alcohol; the *Dublin*, four ounces of the bark in coarse powder, and two pints of the menstruum. The former College digests, the latter macerates, for seven days.

The tincture has the properties of cascarilla, but is never used in this country. W.

TINCTURA CASTOREI. *U.S., Lond., Ed.* TINCTURA CASTOREI ROSSICI. *Dub.* *Tincture of Castor.*

"Take of Castor, bruised, *two ounces;* Alcohol *two pints.* Macerate for seven days, and filter through paper." *U.S.*

The *London* process corresponds with the above, except that the castor is directed in powder. The *Dublin College* employs the same proportions, but specifies the Russian Castor, and directs diluted alcohol or proof spirit, instead of alcohol or rectified spirit. The *Edinburgh College* takes an ounce and a half of castor in powder, and a pound of alcohol, and digests for seven days.

As castor yields little if any of its virtues to water, alcohol is a better solvent than proof spirit. It is said also to form a more grateful preparation. The Russian Castor should always be preferred when attainable. This tincture is used for the same purposes with castor in substance. The dose is from thirty minims to two fluidrachms. W.

TINCTURA CASTOREI COMPOSITA. *Ed.* *Compound Tincture of Castor.*

"Take of Castor, in powder, *an ounce;* Assafetida *half an ounce;* Ammoniated Alcohol *a pound.* Digest for seven days, and filter through paper." *Ed.*

This is an active stimulant and antispasmodic, applicable to cases of severe spasm of stomach, and to various hysterical and other nervous affections, unattended with inflammatory symptoms. The dose is from thirty minims to two fluidrachms. W.

TINCTURA CATECHU. *U.S., Lond., Dub.* TINCTURA ACACIÆ CATECHU. *Ed.* *Tincture of Catechu.*

"Take of Catechu *three ounces;* Cinnamon, bruised, *two ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S., Lond.*

The *Dublin* process differs from the above only in the period of maceration, which is seven days. The *Edinburgh College* orders three ounces of catechu, two ounces of cinnamon, and two pounds and a half of diluted alcohol; and digests for a week.

This is a grateful astringent tincture, useful in all cases to which catechu is applicable, and in which small quantities of spirit are not objectionable. It may often be advantageously added to cretaceous mixtures in diarrhœa. The dose is from thirty minims to three fluidrachms, which may be given with sweetened water or some mucilaginous liquid, or in Port wine when this is not contra-indicated. W.

TINCTURA CINCHONÆ. *U.S., Lond., Dub.* TINCTURA CINCHONÆ LANCIFOLIÆ. *Ed.* *Tincture of Peruvian Bark.*

"Take of Peruvian Bark, in powder, *six ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

The British Colleges all designate the pale bark. The *London College* orders seven ounces to two pints of proof spirit, macerating for fourteen days; the *Edinburgh*, four ounces to two pounds and a half, digesting for a week; the *Dublin*, four ounces to two pints, digesting also for a week.

Of these tinctures, those of the United States and London Pharmacopœias are to be preferred, as they contain most bark; and in the bitter tinctures it is important that the alcohol should bear as small a proportion to the tonic principles as possible. Even the strongest, however, cannot, in ordinary cases, be given in doses sufficiently large to obtain the full effect of the bark, without stimulating too highly. The tincture of cinchona is used chiefly as an adjunct to the infusion or decoction, to a dose of which it may be added in the quantity of from one to four fluidrachms. W.

TINCTURA CINCHONÆ AMMONIATA. *Lond.* *Ammoniated Tincture of Peruvian Bark.*

"Take of the Bark of the Cinchona lancifolia [pale bark] *four ounces;* Aromatic Spirit of Ammonia *two pints.* Macerate for ten days, and filter." *Lond.*

This is an injudicious preparation, as the tonic properties of the bark are entirely lost in the stimulant action of the ammonia and alcohol. It is seldom if ever used. W.

TINCTURA CINCHONÆ COMPOSITA. *U.S., Lond., Ed., Dub.* *Compound Tincture of Peruvian Bark.*

"Take of Peruvian Bark, in powder, *two ounces;* Orange Peel [dried] *an ounce and a half;* Virginia Snakeroot, bruised, *three drachms;* Saffron, Red Saunders rasped, each, *a drachm;* Diluted Alcohol *twenty fluidounces.* Macerate for fourteen days, and filter through paper." *U. S.*

The British Colleges direct two scruples of cochineal in place of the red saunders, and specify the pale bark as the variety to be used. The *Dublin College* employs only half an ounce of orange peel. The *Edinburgh College* orders twenty ounces of alcohol (by weight), and digests for a week. In other respects, the processes correspond with that of the U.S. Pharmacopœia.

This is the preparation commonly known by the name of *Huxham's tincture of bark.* It is an excellent stomachic cordial, and, though too feeble in the principles of cinchona to serve as a substitute for that tonic when its full effect upon the system is required, may be very usefully employed as an addition to the decoction or infusion, or to the salts of quinia, in low forms of fever, particularly in malignant intermittents, and typhoid remittents. Huxham was in the habit of uniting with it the *elixir of vitriol,* the aromatic sulphuric acid of the Pharmacopœias. The dose is from one to four fluidrachms. W.

TINCTURA CINNAMOMI. *U.S., Lond., Dub.* TINCTURA LAURI CINNAMOMI. *Ed.* *Tincture of Cinnamon.*

"Take of Cinnamon, bruised, *three ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days and filter through paper." *U. S., Lond.*

The *Dublin* process differs from the above only in the quantity of cinnamon, which is hree ounces and a half. The *Edinburgh College* takes three ounces of cinnamon and two pounds and a half of diluted alcohol, and digests for a week.

This tincture has the aromatic and astringent properties of cinnamon, and may be used as an adjuvant to cretaceous mixtures, and astringent infusions or decoctions. The dose is from one to three or four fluidrachms. W.

TINCTURA CINNAMOMI COMPOSITA. *U.S., Lond., Ed.* *Compound Tincture of Cinnamon.*

"Take of Cinnamon, bruised, *six drachms;* Cardamom [seeds], bruised, *three drachms;* Ginger, bruised, *two drachms;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

The *London College* orders, in addition to the ingredients above mentioned, two drachms of powdered long pepper. The *Edinburgh College* orders of cinnamon and cardamom, each, an ounce; of diluted alcohol two pounds and a half; and digests for a week.

This is a very warm aromatic tincture, useful in flatulence, spasm of the stomach, and gastric debility. The dose is one or two fluidrachms. W.

TINCTURA SEMINUM COLCHICI. *Dub.* *Tincture of Meadow-Saffron Seeds.*

"Take of Meadow-saffron Seeds *two ounces;* Proof Spirit *a pint.* Macerate for fourteen days, and filter." *Dub.*

This tincture possesses the active properties of colchicum, and may be given whenever that medicine is indicated; but the wine, which contains less alcohol, is generally preferred. The dose is from ten to sixty drops. W.

TINCTURA COLOMBÆ. *U.S., Ed., Dub.* TINCTURA CALUMBÆ. *Lond.* *Tincture of Columbo.*

"Take of Columbo, bruised, *two ounces and a half;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

The processes of the *London* and *Dublin Colleges* are the same with the above, the columbo being sliced instead of bruised. The *Edinburgh College* takes two ounces of the powdered root, and two pounds of diluted alcohol, and digests for seven days.

The tincture of columbo may be added to tonic infusions or decoctions, to increase their stimulant power; but, like all the other bitter tinctures, should be used with caution. It is especially applicable to the cases of drunkards. The dose is from one to four fluidrachms. W.

TINCTURA CONII. *Dub.* TINCTURA CONII MACULATI. *Ed.* *Tincture of Hemlock.*

"Take of Hemlock Leaves, dried, *two ounces;* Cardamom Seeds, bruised, *an ounce;* Proof Spirit *a pint.* Macerate for seven days, and filter." *Dub.*

The *Edinburgh College* takes two ounces of the dried leaves, half an ounce of cardamom, and sixteen ounces (by weight) of diluted alcohol, digests for seven days, and filters through paper.

This tincture affords a convenient method of administering hemlocks, the virtues of which it possesses. The dose is from thirty minims to a fluidrachm. W.

TINCTURA CROCI SATIVI. *Ed.* *Tincture of Saffron.*

"Take of Saffron, cut into shreds, *an ounce;* Diluted Alcohol *fifteen ounces* [by weight]. Digest for seven days and filter through paper." *Ed.*

This tincture possesses all the properties of saffron; but is of little other use than to impart colour to mixtures. W.

TINCTURA DIGITALIS. *U.S., Lond., Dub.* TINCTURA DIGITALIS PURPUREÆ. *Ed.* *Tincture of Foxglove.*

"Take of Foxglove [dried leaves] *four ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S., Lond.*

The *Edinburgh College* orders an ounce of the dried leaves, and eight ounces (by weight) of diluted alcohol; and digests for a week. The *Dublin College* directs two ounces of the dried leaves, (the larger being rejected,) in coarse powder, and a pint of proof spirit; and macerates for a week.

In preparing this tincture, great attention should be paid to the selection of the leaves, according to the rules laid down under the head of Digitalis. From a neglect of these, it is apt to be weak or inefficient. We have observed, in our own experience, a decided superiority in the tincture prepared from carefully preserved leaves imported from England. The tincture of foxglove possesses all the virtues of that narcotic, and affords a convenient method of administering it, especially in mixtures. The dose is ten drops, to be repeated two or three times a day, and increased, if necessary, with great caution. (See *Digitalis.*) W.

TINCTURA GALBANI. *Dub.* *Tincture of Galbanum.*

"Take of Galbanum, cut into small pieces, *two ounces;* Proof Spirit *two pints.* Digest for seven days, and filter." *Dub.*

The tincture of galbanum is analogous in properties to that of assafetida, but weaker, and less nauseous. It is very seldom used. The dose is from one to three fluidrachms. W.

TINCTURA GALLARUM. *Ed., Dub.* *Tincture of Galls.*

"Take of Galls, in powder, *four ounces;* Proof Spirit *two pints.* Digest for seven days, and filter." *Dub.*

The *Edinburgh College* takes two ounces of galls, and sixteen of diluted alcohol, and digests as above.

The tincture of galls is powerfully astringent; but is more used as a test than as a medicine. The dose is from one to three fluidrachms. W.

TINCTURA GENTIANÆ. *U.S.* TINCTURA GENTIANÆ COMPOSITA. *Lond., Ed., Dub.* *Tincture of Gentian.*

"Take of Gentian, bruised, *two ounces;* Orange Peel [dried] *an ounce;* Cardamom [seeds], bruised, *half an ounce;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

The processes of the *London* and *Dublin Colleges* are essentially the same with the above. The *Edinburgh College* substitutes for the cardamom an equal weight of bruised canella alba, adds half a drachm of powdered cochineal to the other ingredients, and digests for a week with two pounds and a half of diluted alcohol.

This is an elegant bitter, much used in dyspepsia, and as an addition to tonic mixtures in debilitated states of the digestive organs, or of the system generally. There is, however, much danger of its abuse, especially in chronic cases. The dose is one or two fluidrachms. W.

TINCTURA GUAIACI. *U.S., Lond., Dub.* TINCTURA GUAIACI OFFICINALIS. *Ed.* *Tincture of Guaiac.*

"Take of Guaiac, in powder, *half a pound;* Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

The *London* process agrees with that of the United States Pharmacopœia. The *Edinburgh College* orders six ounces of guaiac and two pounds and a half of alcohol, and digests for a week. The *Dublin College* directs four ounces of the guaiac and two pints of alcohol, and macerates for a week.

This tincture is given in chronic rheumatism and gout, in the dose of from one to three fluidrachms three or four times a day. As it is decomposed by water, it is most conveniently administered in mucilage, sweetened water, or milk, by which the separated guaiac is held in temporary suspension. The following is a form of tincture of guaiac which Dr. Dewees has found very efficient in the cure of suppression of the menses, and dysmenorrhœa. "Take of the best Guaiac, in powder, *four ounces;* Carbonate of Soda or of Potassa *one drachm and a half;* Pimento, in powder, *an ounce;* Diluted Alcohol *a pound.* Digest for a few days." The dose is a teaspoonful three times a day, to be gradually increased if necessary. Within our own experience, this remedy has proved highly useful in painful menstruation, given in the intervals of the attacks. The quantity of alkaline carbonate is too small to produce any sensible effect, and the pimento can act only as a spice; so that the virtues of the tincture reside in the guaiac, and the officinal tincture would probably be found equally effectual. W.

TINCTURA GUAIACI AMMONIATA. *U.S., Lond., Ed., Dub.* *Ammoniated Tincture of Guaiac.*

"Take of Guaiac, in powder, *four ounces;* Aromatic Ammoniated Alcohol *a pint and a half.* Macerate for fourteen days, and filter through paper." *U.S.*

The processes of the British Colleges correspond with the above, except that the *Edinburgh College* directs a pound and a half of ammoniated alcohol instead of a pint and a half, and both this and the *Dublin College* shorten the period, the former of digestion, the latter of maceration, to a week.

This tincture is very celebrated in the treatment of chronic rheumatism. It is more stimulating and is thought to be more effectual than the preceding. Like that, it is decomposed by water, and should be administered in some viscid or tenacious vehicle which may hold the guaiac in suspension. The dose is one or two fluidrachms. W.

TINCTURA HELLEBORI NIGRI. *U.S., Lond., Ed., Dub.* *Tincture of Black Hellebore.*

"Take of Black Hellebore, bruised, *four ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

The *London* and *Dublin* processes correspond with the above, except that in the latter, the maceration is continued only for a week. The *Edinburgh College* takes two ounces of the bruised root, fifteen grains of powdered cochineal, and fifteen ounces (by weight) of diluted alcohol, and digests for a week.

This tincture possesses the properties of black hellebore, and upon the recommendation of Dr. Mead, has been much used in suppression of the menses. It is said to be peculiarly applicable to cases in which the grade of action is too high for the use of chalybeates. At best, however, it is an uncertain remedy, and should always be administered with caution, as it is sometimes violent in its action. The dose is from thirty minims to a fluidrachm, to be taken night and morning. W.

TINCTURA HUMULI. *U.S., Lond., Dub.* TINCTURA HUMULI LUPULI. *Ed.* *Tincture of Hops.*

"Take of Hops *five ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days; then express the liquor, and filter through paper," *U.S.*

The *London* and *Dublin* processes differ from the above only in the omission of expression. The *Edinburgh College* employs two pounds and a half of diluted alcohol, and digests for a week.

Hops are so light and bulky, that, in the proportion directed, they absorb almost all the spirit, which, after the requisite maceration, can be separated only by strong pressure. As this absorption of the spirit obstructs its proper action on all parts of the hops, it is necessary that the mixture should be frequently stirred during the maceration. By thoroughly drying the hops and rubbing them between the hands, or by cutting and bruising them, they may be brought to a state of division which will in great measure obviate the disadvantages alluded to. As the virtues of hops depend chiefly on the lupulin, and as the quantity of this substance is not the same in different parcels, the tincture is necessarily unequal in strength; and the tincture of lupulin itself is greatly preferable. (See *Tinctura Lupulinæ.*) The tincture of hops is tonic and narcotic, and has been proposed as a substitute for laudanum when the latter disagrees with the patient; but little reliance can be placed upon it. The condition of disease to which it appears to be best adapted, is the wakefulness, attended with tremors and general nervous derangement, to which habitual drunkards are liable, and which frequently precedes an attack of delirium tremens. The dose is from one to three fluidrachms. W.

TINCTURA HYOSCYAMI. *U.S., Lond., Dub.* TINCTURA HYOSCYAMI NIGRI. *Ed.* *Tincture of Henbane.*

"Take of Henbane [dried leaves], in powder, *four ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S. Lond.*

The *Edinburgh College* takes an ounce of the dried leaves and eight ounces (by weight) of diluted alcohol; the *Dublin*, five ounces of the former and two pints of the latter; and both Colleges digest for a week.

This tincture may be advantageously substituted, as an anodyne and soporific, for that of opium, when the latter disagrees with the patient, or is objectionable on account of its property of inducing constipation. When the tincture of henbane purges, as it sometimes does, it should be united with a very small proportion of laudanum, The dose is a fluidrachm. W.

TINCTURA IODINI. *U.S.* IODINII TINCTURA. *Dub.* *Tincture of Iodine.*

"Take of Iodine *half an ounce;* Alcohol *half a pint.* Dissolve the Iodine in the Alcohol." *U.S.*

The *Dublin College* takes two scruples of iodine, and an ounce (by weight) of rectified spirit, mixes, dissolves the iodine with the aid of heat, and keeps the solution in a well stopped phial.

The proportion of the Dublin College is one part of iodine to twelve of alcohol by weight, the same with that employed by Dr. Coindet. In the tincture of the United States Pharmacopœia, the proportion is one of iodine to about 12.7 of alcohol, sufficiently near the former to allow the two preparations to be considered identical for all practical purposes. We prefer the first process, as it conforms with those for the other tinctures in the use of a measured quantity instead of a certain weight of the menstruum. Dr. Coindet employed 48 grains to the French ounce (*poids de marc*)=576 grains; and it has been customary, in preparing the tincture, to employ the same quantity to the troy ounce, without attention to the fact that the latter contains only 480 grains, and is incapable of dissolving the whole of the iodine, the tincture of Coindet being a saturated or nearly saturated solution. It is best to prepare the tincture in small quantities only at a time; as there is reason to apprehend that the iodine may be acted on by the alcohol, and converted into ioduretted hydriodic acid by union with its hydrogen. The iodine should be freed from moisture before being weighed out. The tincture should be kept in well stopped bottles, in order to prevent the evaporation of the alcohol, and the consequent crystallization of the iodine.

The tincture of iodine has a deep brown colour. Sixteen minims, equal to about thirty-five drops, contain one grain of iodine. The dose is from ten to twenty drops, which may be gradually increased to thirty or forty drops, three times a day. It should be given in sweetened water. W.

TINCTURA JALAPÆ. *U.S., Lond., Dub.* TINCTURA CONVOLVULI JALAPÆ. *Ed. Tincture of Jalap.*

"Take of Jalap, in powder, *eight ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

The *London* and *Dublin* processes correspond with the above. The *Edinburgh College* takes three ounces of jalap and fifteen ounces (by weight) of diluted alcohol, and digests for seven days.

This tincture possesses the medical virtues of jalap, and is sometimes added to cathartic mixtures in the quantity of one or two fluidrachms, to increase their activity. W.

TINCTURA KINO. *Lond., Ed., Dub. Tincture of Kino.*

"Take of Kino, in powder, *three ounces;* Rectified Spirit *two pints.* Macerate for fourteen days, and filter." *Lond.*

The *Dublin College* uses the same proportions, but employs proof spirit or diluted alcohol, and macerates only for seven days. The *Edinburgh College* takes two ounces of kino and a pound and a half of diluted alcohol, and digests for a week.

This tincture, prepared with the kino brought into the United States, almost always becomes gelatinous when kept, and loses its astringency. It is, therefore, an ineligible preparation, and has been properly omitted in the last edition of the United States Pharmacopœia. The tincture of catechu should be substituted, or the kino employed in the state of filtered watery solution. The dose of the tincture is one or two fluidrachms. It is used chiefly as an addition to cretaceous and other astringent mixtures, in diarrhœa. W.

TINCTURA LOBELIÆ. *U.S. Tincture of Indian Tobacco.*

"Take of Indian Tobacco [the herb] *four ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

This tincture possesses the emetic and narcotic properties of lobelia, and is sometimes used in asthma, in the dose of one or two fluidrachms, repeated every two or three hours till its effects are experienced. W.

TINCTURA LUPULINÆ. *U.S. Tincture of Lupulin.*

"Take of Lupulin *four ounces;* Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

This is much superior to the tincture of hops of the former United States Pharmacopœia, in the place of which it was introduced into the last edition. In the original preparation, a certain quantity of hops was directed, from which the lupulin was to be separated by beating, and then digested in alcohol. As hops contain a variable proportion of lupulin, a tincture thus prepared must be of unequal strength; an objection to which the tincture of hops, however prepared, is liable. Besides, the amount of lupulin contained in any quantity of hops upon which alcohol can conveniently act, is too small in proportion to the alcohol, to afford a tincture of the due strength. The present tincture is, therefore, in all respects, preferable. The dose is one or two fluidrachms, to be given in sweetened water or some mucilaginous fluid. W.

TINCTURA MOSCHI. *U.S., Dub.* *Tincture of Musk.*

"Take of Musk *two drachms;* Alcohol *a pint.* Macerate for seven days, and filter through paper." *U.S.*

The *Dublin College* employs the same ingredients, and in the same proportions, but uses the musk *in powder*, and *digests* for a week.

This tincture is much too feeble in musk to be capable of producing beneficial effects in any dose which would not contain too large a quantity of alcohol. Musk should always be given in substance. W.

TINCTURA MYRRHÆ. *U.S., Lond., Ed., Dub.* *Tincture of Myrrh.*

"Take of Myrrh, bruised, *four ounces;* Alcohol *three pints.* Macerate for fourteen days, and filter through paper." *U.S.*

The *London* process corresponds with the above. The *Edinburgh College* directs three ounces of powdered myrrh, twenty ounces (by weight) of alcohol, and ten ounces of water; and digests for seven days. The *Dublin College* takes three ounces of bruised myrrh, a pint and a half of proof spirit, and half a pint of rectified spirit; and digests for a week.

Undiluted alcohol, as directed by the U. S. and London Pharmacopœias, is preferable, as a solvent of myrrh, to that fluid mixed with water; because it forms a perfectly clear solution, which is not attainable with the latter menstruum. The tincture of myrrh is scarcely ever used internally. As a local application it is employed to stimulate indolent and foul ulcers, and promote the exfoliation of bones, and, diluted with water, is applied to spongy gums, aphthous sore mouth, and ulcerations of the throat. The dose, as a stimulant expectorant and emmenagogue, is from half a fluidrachm to a fluidrachm.

Off. Prep. Tinctura Aloës et Myrrhæ. *U.S., Lond., Dub.* W.

TINCTURA NUCIS VOMICÆ. *Dub.* *Tincture of Nux Vomica.*

"Take of Nux Vomica, rasped, *two ounces;* Rectified Spirit *eight ounces.* Macerate for seven days, and filter." *Dub.*

The tincture is not an eligible form for administering the nux vomica, as it is equally uncertain with the medicine in substance, and has the disadvantage of excessive bitterness. The alcoholic extract, or strychnia is preferable. The dose of the tincture is from five to twenty drops. W.

TINCTURA OPII. *U.S., Lond., Ed., Dub.* *Tincture of Opium:*

"Take of Opium, in powder, *two ounces and a half;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

The processes of the *London* and *Dublin Colleges* correspond with the above. The *Edinburgh College* directs two ounces of opium and two pounds of diluted alcohol, and digests for seven days.

The proportion of opium in the Edinburgh formula is so nearly the same with that employed in the others, that the resulting tinctures may be considered identical. In the original edition of the U. S. Pharmacopœia, the proportion of an ounce of opium to the pint of diluted alcohol was adopted, under the mistaken impression, that the pound of the Edinburgh Pharmacopœia, from which the process was taken, was equivalent to a pint; whereas it is in fact equal to no more than 0.79 of a pint of water, or about 0.845 of a pint of the officinal diluted alcohol. The tincture was therefore much weaker than that used in Great Britain. The error was corrected in the last edition of the Pharmacopœia, so that uniformity in relation to this preparation has now been established.

In the United States and Great Britain, this tincture is universally known by the name of *laudanum*. As this term was formerly applied to other preparations of opium, and still continues to be so on the Continent of Europe, the tincture is sometimes distinguished by the epithet *liquidum*, which, however, is seldom used in this country. *Tinctura Thebaica* is another title by which this preparation is known.

About two-thirds of the opium used in the preparation of the tincture are dissolved, the residue consisting chiefly of inert matter. Allowing the opium to be wholly exhausted of its active principles, one grain would be represented by 12.8 minims; but a small quantity of morphia has been detected in the residuary matter, so that the tincture is rather weaker than the proportion of opium employed would indicate.

The tincture of opium is used for all the purposes to which opium itself is applied. (See *Opium.*) The dose, equivalent to a grain of opium, is about thirteen minims, or twenty-five drops. It should be recollected, that a fluidrachm or teaspoonful of laudanum (sixty minims) will afford, on an average, about one hundred and twenty drops. Laudanum, when long kept, with occasional exposure to the air, becomes thick, in consequence of the evaporation of a portion of the alcohol, and the deposition of opium. If given in this state, it often acts with unexpected energy; and cases of death have resulted in infants from its use in doses which would have been entirely safe if the tincture had been clear.

Off. Prep. Enema Opii, *Dub.;* Liniment. Saponis cum Opio, *Dub.* W.

TINCTURA OPII ACETATA. *U.S.* *Acetated Tincture of Opium.*

"Take of Opium *two ounces;* Vinegar *twelve fluidounces;* Alcohol *half a pint.* Rub the Opium with the Vinegar; then add the Alcohol, and, having macerated for fourteen days, filter through paper." *U.S.*

This preparation was introduced into the last edition of our Pharmacopœia as a substitute for the *Acetum Opii* or *black drop* of the original work, the advantages of which it possesses, without being liable to the same objection of uncertainty of strength. The following directions for the preparation of the black drop were given in the first edition of the U. S. Pharmacopœia. "Take of Opium *half a pound;* Vinegar *three pints;* Nutmeg, bruised, *one ounce and a half;* Saffron *half an ounce.* Boil them to a proper consistence; then add, Sugar *four ounces;* Yeast *one fluidounce.* Digest for seven weeks, then place in the open air until it becomes a syrup; lastly, decant, filter, and bottle it up, adding a little sugar to each bottle." The merest tyro will discover in this process sources of uncertainty in the resulting preparation, which must very much detract from its value, and in fact render it unworthy of a place in a standard work. The *boiling to a proper consistence*, the digestion in the open air *until a syrup is formed*, the addition of a *little sugar* to each bottle, are all indefinite directions; and the practical result has been, that the *black drop* prepared according to them has no certain strength. The only advantage of the black drop over laudanum, is, probably, that the morphia exists in it in the state of an acetate. This advantage is secured in the acetated tincture of opium, the strength of which is as uniform as that of the opium from which it is prepared. This tincture was originally employed by Dr. Joseph Hartshorne of Philadelphia. The *black drop* has long been used under the name of *Lancaster* or *Quaker's black drop*, and the process for preparing it was first published by Dr. Armstrong, who found it among the papers of a relative of the original proprietor in England. In the original process, however, verjuice, or the juice of the wild crab, was employed instead of vinegar. Other vegetable acids also favourably modify the narcotic operation of opium; and lemon juice has been employed in a similar manner with vinegar or verjuice, and perhaps not less advantageously. The average product of the process for *acetum opii*, when carefully conducted, may be stated at *two pints*, and the strength of the preparation is such, that one drop is about equal to three of laudanum.

The *acetated tincture of opium* may often be advantageously used in cases in which laudanum or opium itself produces unpleasant effects, such as nausea and vomiting, intense headach, great nervous disorder, &c., but the introduction of the salts of morphia into use has in great measure superseded the necessity of the preparation. The dose is ten minims, or about twenty drops, equivalent to a grain of opium. W.

TINCTURA OPII AMMONIATA. *Ed.* *Ammoniated Tincture of Opium.*

"Take of Opium *two drachms;* Saffron, sliced, Benzoic Acid, each, *three drachms;* Oil of Aniseed *half a drachm;* Ammoniated Alcohol *sixteen ounces.* Digest for seven days, and filter through paper." *Ed.*

This tincture is used in Scotland under the title of *paregoric elixir*, but differs both in composition and strength from the preparation known by that name in the United States. It is employed in spasmodic complaints, such as whooping cough and asthma. Each fluidrachm contains about a grain of opium. W.

TINCTURA OPII CAMPHORATA. *U.S.*, *Ed.*, *Dub.* TINCTURA CAMPHORÆ COMPOSITA. *Lond.* *Camphorated Tincture of Opium. Paregoric Elixir.*

"Take of Opium, in powder, Benzoic Acid, Oil of Anise, each, *a drachm;* Liquorice [extract] *half an ounce;* Clarified Honey *two ounces;* Camphor *two scruples;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

None of the *British Colleges* employ liquorice or honey, and the *Dublin* alone, oil of anise. The *Edinburgh College* directs two pounds and a half of diluted alcohol, and digests for a week. In other respects their processes correspond with ours.

This is the well known *paregoric elixir.* It is a very pleasant anodyne and antispasmodic, much used to allay cough in chronic catarrh, asthma, consumption, pertussis, &c.; to relieve nausea and slight pains in the stomach and bowels; and, in infantile cases, to procure sleep. Half a fluidounce contains rather less than a grain of opium. The dose for an infant is from five to twenty drops, for an adult from one to two fluidrachms.* W.

---

* The following formulæ have been adopted by the Philadelphia College of Pharmacy for the preparation of the two compound tinctures of opium so much used under the names of *Bateman's drops*, and *Godfrey's cordial.* So long as these nostrums are employed, it is important that they should be prepared in a uniform manner, and of a certain strength; as serious consequences may happen from diversity in the formulæ, when so active a substance as opium is the chief ingredient. Such diversity has existed to a very great extent, so much so that in one formula for Bateman's drops the quantity of opium was seven and a half grains to the pint, while in another it exceeded one hundred grains. It was in order to remedy this inconvenience, that the College was induced to adopt the formulæ here presented.

"*Bateman's pectoral drops.* Take of Diluted Alcohol Cong. iv., Red Saunders, rasped, ℥ij. Digest for twenty-four hours, filter, and add of Opium in powder ʒij., Catechu in powder ℥ij., Camphor ʒij., Oil of Anise fʒiv. Digest for ten days." This preparation

TINCTURA PIPERIS CUBEBÆ. *Dub.* *Tincture of Cubebs.*

"Take of Cubebs *four ounces;* Proof Spirit *two pints.* Macerate for fourteen days, and filter." *Dub.*

This may be used as a carminative, and has been applied with advantage to the treatment of gonorrhœa in the advanced stages. The dose is one or two fluidrachms. W.

TINCTURA QUASSIÆ. *U.S., Dub.* TINCTURA QUASSIÆ EXCELSÆ. *Ed.* *Tincture of Quassia.*

"Take of Quassia, rasped, *an ounce;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

The *Edinburgh College* uses two pounds and a half of diluted alcohol, and digests for seven days; the *Dublin College* macerates for seven days; in other respects their processes agree with ours.

This tincture may be employed as an addition to tonic infusions or mixtures, in the quantity of one or two fluidrachms at a dose. It is a pure and intense bitter. W.

TINCTURA RHEI. *U.S., Lond., Ed.* *Tincture of Rhubarb.*

"Take of Rhubarb, bruised, *three ounces;* Cardamom [seeds], bruised, *half an ounce;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

The *London College* employs but two ounces of rhubarb, and adds two drachms of saffron; the *Edinburgh* employs two pounds and a half of diluted alcohol, and digests for a week. In other respects their processes are the same with the above. W.

TINCTURA RHEI COMPOSITA. *Lond., Dub.* *Compound Tincture of Rhubarb.*

"Take of Rhubarb, sliced, *two ounces;* Liquorice Root, bruised, *half an ounce;* Ginger Root, sliced, Saffron, each, *two drachms;* Proof Spirit *a pint;* Water *twelve fluidounces.* Macerate for fourteen days, and filter." *Lond.*

The *Dublin College* substitutes half an ounce of cardamom seeds, husked and bruised, for the ginger, employs as the menstruum two pints of proof spirit, and macerates for seven days.

TINCTURA RHEI ET ALOES. *U.S., Ed.* *Tincture of Rhubarb and Aloes.* *Elixir Sacrum.* *Sacred Elixir.*

"Take of Rhubarb, bruised, *ten drachms;* Aloes, in powder, *six drachms;* Cardamom [seeds], bruised, *half an ounce;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

The *Edinburgh College* specifies Socotrine Aloes, employs two pounds and a half of diluted alcohol, and digests for a week.

TINCTURA RHEI ET GENTIANÆ. *U.S., Ed.* *Tincture of Rhubarb and Gentian.*

---

is about equal in strength to the camphorated tincture of opium or paregoric elixir of the U.S. Pharmacopœia, containing about two grains of opium to the fluidounce.

"*Godfrey's cordial.* Take of Tincture of Opium Oiss., Molasses (from the sugar refiners) Oxvj., Alcohol Oij., Water Oxxvj., Carbonate of Potassa ℥iiss., Oil of Sassafras f ʒiv. Dissolve the Carbonate of Potassa in the Water, add the Molasses, and heat over a gentle fire till they simmer; take off the scum which rises, and add the Laudanum and Oil of Sassafras, having previously mixed them well together." This preparation contains the strength of rather more than one grain of opium in a fluidounce. *Journ. of the Phil. Col. of Pharm.* v. 26 and 27.

"Take of Rhubarb, bruised, *two ounces;* Gentian, bruised, *half an ounce;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

The *Edinburgh College* employs two pounds and a half of diluted alcohol, and digests for a week.

The above tinctures of rhubarb are all in a greater or less degree purgative, stomachic, and tonic; but, except in low states of the system, or in cases of individuals accustomed to the use of ardent spirits, they are too feebly cathartic in proportion to their stimulant power, to be advantageously employed, unless as adjuvants to other medicines. Combined with the neutral salts or other laxatives, or with tonic and stomachic mixtures, infusions, &c., they serve to render them warmer and more cordial to the stomach, and often prove beneficial in flatulent colic, dyspepsia, the costiveness of cold inirritable habits, diarrhœa, and other analogous complaints. One of them is to be preferred to another, according as its peculiar composition may, in the judgment of the practitioner, appear to adapt it to the circumstances of the case under treatment. In low forms of fever, when the indication is to evacuate the bowels, and at the same time stimulate the patient, the simple tincture (Tinctura Rhei) may be very advantageously used in doses of two or three fluidrachms, repeated at proper intervals till it operates. The ordinary dose of these tinctures, as purgatives, is from half a fluidounce to a fluidounce; as stomachics from one to two or three fluidrachms. W.

TINCTURA RHEI ET SENNÆ. *U.S.* *Tincture of Rhubarb and Senna.*

"Take of Rhubarb, bruised, *an ounce;* Senna *two drachms;* Coriander [seeds] bruised, Fennel-seed, bruised, each, *a drachm;* Red Saunders, rasped, *two drachms;* Saffron, Liquorice [extract], each *half a drachm;* Raisins, stoned, *half a pound;* Diluted Alcohol *three pints.* Macerate for fourteen days, and filter through paper." *U.S.*

This is the stomachic so well known, and so much used in this country, under the name of *Warner's gout cordial.* It is a feeble purgative, usually very acceptable to the stomach, and well adapted to cases of costiveness, with gastric uneasiness, in persons of a gouty habit, and accustomed to the free use of wine or other stimulant drink. The dose is from half a fluidounce to two fluidounces. W.

TINCTURA SANGUINARIÆ. *U.S.* *Tincture of Blood-root.*

"Take of Blood-root, bruised, *four ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

This will prove emetic in the dose of three or four fluidrachms; but it is rather intended to act as a stimulant to the stomach, or as an alterative, for which purposes it may be given in the quantity of from thirty to sixty drops. W.

TINCTURA SAPONIS CAMPHORATA. *U.S., Ed.* LINIMENTUM SAPONIS COMPOSITUM. *Lond.* LINIMENTUM SAPONIS. *Dub.* *Camphorated Tincture of Soap.*

"Take of Soap [Castile soap], in shavings, *four ounces;* Camphor *two ounces;* Oil of Rosemary *half a fluidounce;* Alcohol *two pints.* Digest the Soap with the Alcohol in a water-bath till it is dissolved; then filter, and add the Camphor and Oil." *U.S.*

The *London* and *Dublin Colleges* take three ounces of hard soap, an ounce of camphor, and a pint of spirit of rosemary. The former dissolves the camphor in the spirit, then adds the soap, and macerates in a sand-bath till it is dissolved; the latter digests the soap in the spirit till it is dissolved, and then adds the camphor. The *Edinburgh* process scarcely differs from that of the U. S. Pharmacopœia, half an ounce of the oil being employed instead of half a fluidounce, two pounds of alcohol instead of two pints, and the digestion being performed without a water-bath, and continued for three days.

It is necessary, in preparing this tincture, that the soap employed should not have been made with animal oil, as otherwise a portion will be deposited as the solution cools. The soap indicated by the U. S. Pharmacopœia is that "prepared from soda and olive oil," commonly called *Castile soap.* The preparation is usually called *soap liniment*, a name which more properly belongs to the *Linimentum Saponis Camphoratum* of the Pharmacopœia, or common *opodeldoc.*

The camphorated tincture of soap is much used, as an anodyne and gently rubefacient embrocation, in sprains, bruises, and local rheumatic or gouty pains.

Off. Prep. Linimentum Saponis cum Opio, *Dub.* W.

TINCTURA SAPONIS ET OPII. *Ed.* LINIMENTUM SAPONIS CUM OPIO vel LINIMENTUM ANODYNUM. *Dub.* *Tincture of Soap and Opium.*

"Take of Hard Soap, in shavings, *four ounces;* Opium *an ounce;* Camphor, *two ounces;* Oil of Rosemary *half an ounce;* Alcohol *two pounds.* Digest the Soap and Opium in the Alcohol for three days; then add to the filtered liquor the Camphor and Oil, and shake them well." *Ed.*

The *Dublin College* merely mixes four parts by measure of their liniment of soap (Tinctura Saponis Camphorata) with three parts of tincture of opium.

This tincture is commonly known by the name of *anodyne liniment*, and is employed for the same purposes with the preceding, from which it differs only in containing opium. It is most conveniently prepared by extemporaneously mixing the camphorated tincture with laudanum, as directed by the Dublin College. W.

TINCTURA SCILLÆ. *U.S., Lond., Dub.* TINCTURA SCILLÆ MARITIMÆ. *Ed.* *Tincture of Squill.*

"Take of Squill *four ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

The *London* process agrees with the above, freshly dried squill being directed. The *Dublin College*, using the same ingredients in the same proportions, directs that they should be macerated for seven days, then set aside, and the clear liquor decanted when the dregs have subsided. The *Edinburgh College* directs two ounces of the freshly dried squill and sixteen ounces (by weight) of diluted alcohol, and digests for a week.

The tincture possesses all the virtues of squill, and may be given for the same purposes, whenever the spirituous menstruum is not objectionable. The dose as an expectorant or diuretic is from ten to twenty minims (twenty to forty drops), and the latter quantity usually nauseates. W.

TINCTURA SENNÆ. *Lond.* TINCTURA SENNÆ COMPOSITA. *Dub.* *Tincture of Senna.*

"Take of Senna Leaves *three ounces;* Caraway Seeds, bruised, *three drachms;* Cardamom Seeds, bruised, *a drachm;* Raisins, stoned, *four ounces;* Proof Spirit *two pints.* Macerate for fourteen days, and filter." *Lond.*

The *Dublin* process differs from the above only in omitting the raisins, and quadrupling the quantities of the other ingredients.

This tincture is the *elixir salutis* of the old Pharmacopœias. It is a warm cordial purgative, useful in costiveness attended with flatulence, and in atonic gout, especially when occurring in intemperate persons. It is also added to cathartic infusions and mixtures. The dose is from two fluidrachms to a fluidounce or more. W.

TINCTURA SENNÆ ET JALAPÆ. *U.S.* TINCTURA SENNÆ COMPOSITA. *Ed.* *Tincture of Senna and Jalap.*

"Take of Senna *three ounces;* Jalap, bruised, *an ounce;* Coriander [seeds] bruised, Caraway [seeds] bruised, each, *half an ounce;* Cardamom [seeds] bruised, *two drachms;* Sugar [refined] *four ounces;* Diluted Alcohol *three pints.* Macerate for fourteen days, and filter through paper." *U.S.*

The *Edinburgh College* takes two ounces of senna, an ounce of jalap, half an ounce of coriander seeds, and three pounds and a half of diluted alcohol; digests for seven days; then filters, and adds to the filtered liquor four ounces of refined sugar.

This is another form of the *elixir salutis*, and scarcely differs from the preceding in virtues. It is given for the same purposes, and in the same doses. W.

TINCTURA SERPENTARIÆ. *U.S. Lond., Dub.* TINCTURA ARISTOLOCHIÆ SERPENTARIÆ. *Ed.* *Tincture of Virginia Snake Root.*

"Take of Virginia Snakeroot, bruised, *three ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

The *London* and *Dublin Colleges* give the same process with the above, the latter macerating only seven days. The *Edinburgh College* takes two ounces of snakeroot, a drachm of powdered cochineal, and two pounds and a half of diluted alcohol, and digests for a week.

This tincture possesses the tonic and cordial properties of the root, and may be advantageously added to the infusion of Peruvian bark in low states of the system. The dose is one or two fluidrachms. W.

TINCTURA STRAMONII. *U.S.* *Tincture of Thorn-apple.*

"Take of Thorn-apple Seed, bruised, *four ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

This tincture may be used for all the purposes for which stramonium is given, in the dose of from ten to twenty minims, repeated twice or thrice a day, and gradually increased till it obviously affects the sytem. W.

TINCTURA TOLUTANI. *U.S.* TINCTURA TOLUIFERÆ BALSAMI. *Ed.* TINCTURA BALSAMI TOLUTANI. *Dub.* *Tincture of Tolu.*

"Take of Tolu [balsam] *three ounces;* Alcohol *two pints.* Macerate till the Tolu is dissolved, and then filter through paper." *U.S.*

The *Edinburgh College* employs an ounce and a half of the balsam to a pound of alcohol; the *Dublin College* an ounce to the pint.

The tincture of tolu has the properties of the balsam, and may be employed as an addition to expectorant mixtures in chronic catarrhal affections; but the proportion of alcohol is too large to allow of its advantageous use in ordinary cases. The dose is one or two fluidrachms. In smaller quantities it is often employed to flavour cough mixtures. It is decomposed by water.

Off. Prep. Syrupus Balsami Tolutani, *Dub., Ed.* W.

TINCTURA VALERIANÆ. *U.S., Lond., Dub.* *Tincture of Valerian.*

"Take of Valerian, bruised, *four ounces;* Diluted Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

The process of the *London* and *Dublin Colleges* correspond with the above, except that the latter continues the maceration only for a week.

This tincture possesses the properties of valerian, but cannot be given in ordinary cases, so as to produce the full effects of the root, without stimulating too highly in consequence of the large proportion of spirit. The dose is from one to four fluidrachms. W.

TINCTURA VALERIANÆ AMMONIATA. *U.S., Lond., Ed., Dub.* *Ammoniated Tincture of Valerian.*

"Take of Valerian, bruised, *four ounces;* Aromatic Ammoniated Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

The *London* process corresponds with the above. The *Edinburgh College* takes four ounces of powdered valerian, and two pounds and a half of ammoniated alcohol, and digests for a week. The *Dublin College* takes two ounces of the root, and a pint of the ammoniated spirit, and macerates for a week.

The ammonia in this preparation is thought to assist the solvent powers of the alcohol, while it co-operates with the valerian in medical operation. The tincture is employed as an antispasmodic in hysteria and other nervous affections. The dose is one or two fluidrachms, and should be given in sweetened water, milk, or some mucilaginous fluid. W.

TINCTURA VERATRI ALBI. *Ed.* *Tincture of White Hellebore.*

"Take of White Hellebore Root, bruised, *four ounces;* Diluted Alcohol *sixteen ounces* [by weight]. Digest for seven days, and filter through paper. *Ed.*

This tincture has the active properties of the white hellebore. It has been given to assist the action of cathartics, to produce vomiting in maniacal and lethargic affections, and with a view to its alterative effect in cutaneous diseases. But it is a dangerous remedy, producing in overdoses violent purging and vomiting, and not easily regulated as regards the dose. It should always be given in small quantities at first, and cautiously increased till its effects are experienced. The dose to begin with is from five to ten minims. W.

TINCTURA ZINGIBERIS. *U.S., Lond., Dub.* TINCTURA AMOMI ZINGIBERIS. *Ed.* *Tincture of Ginger.*

"Take of Ginger, bruised, *eight ounces;* Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U.S.*

The *London College* takes two ounces of ginger, sliced, and two pints of rectified spirit, and macerates for fourteen days. The *Dublin College* takes two ounces and a half of coarsely powdered ginger, and two pints of rectified spirit, and macerates for seven days. The *Edinburgh College* takes two ounces of bruised ginger, and two pounds and a half of diluted alcohol, and digests for a week.

The tinctures of the British Colleges are too weak with ginger, to be applied advantageously to any other purpose than merely to impart flavour. We greatly prefer the process of the U.S. Pharmacopœia, which yields a preparation in which the virtues of the ginger are not completely swallowed up in the menstruum. In consequence of the mucilaginous matter contained in ginger, the tincture made with diluted alcohol is apt to be turbid. Alcohol is therefore properly preferred by the U.S. and London Pharmacopœias. Good Jamaica ginger should be used.

The tincture of ginger is a useful carminative, and may often be beneficially added to tonic and purgative infusions or mixtures, in debilitated states of the alimentary canal. It is, however, in this country, chiefly used for the preparation of syrup of ginger, for which purpose it is necessary to employ the strong tincture of the U.S. Pharmacopœia.

Off. Prep. Syrupus Zingiberis, *U.S.* W.

TROCHISCI.

Troches.

Troches or lozenges are small, dry, solid masses, usually of a flattened shape, consisting of powders incorporated with sugar and mucilage. They are designed to be held in the mouth, and dissolved slowly in the saliva, and are therefore adapted for the administration of those medicines only which do not require to be given in very large quantities, and are destitute of any very disagreeable flavour. They are much more used, and more skilfully prepared, in Europe than in this country. Tragacanth, from the greater tenacity of its mucilage, is better suited to their formation than gum Arabic, which is in most instances directed by the U.S. and Edinburgh Pharmacopæias. The following directions for preparing them are taken from the *Dictionnaire des Drogues.* A mucilage of tragacanth is first prepared with cold water and strained. With this the powders, including sugar, are thoroughly mixed by rubbing upon a marble slab, and are thus formed into a paste, which is spread out by means of a roller upon the surface of the marble, previously powdered over with a mixture of sugar and starch. The thickness of the extended mass is rendered uniform by a frame upon which the ends of the roller are placed. The upper surface is now covered with a thin layer of sugar and starch, and the mass is divided into small cakes of a particular shape by means of a punch. These cakes are placed upon paper, and having been exposed to the air for twelve hours, are carried into a drying room moderately heated. When perfectly dry, they are thrown upon a sieve to separate the sugar and starch, and are then enclosed in bottles. In this way lozenges may be prepared from almost any medicine which the physician may deem it advisable to administer in that form. The following formula will serve as a guide. Take of citric acid, in powder, a drachm; refined sugar eight ounces; oil of lemons twelve minims; mucilage of tragacanth a sufficient quantity. Form them in the manner above directed into troches of twelve grains each. A species of lozenge is made by uniting the aromatic essential oils with sugar alone; but their preparation belongs to the confectioner rather than to the apothecary. The London and Dublin Pharmacopœias have omitted troches altogether. W.

TROCHISCI CALCIS CARBONATIS. *U.S.* **TROCHISCI CARBONATIS CALCIS.** *Ed.* *Troches of Carbonate of Lime.*

"Take of Prepared Carbonate of Lime *four ounces;* Gum Arabic *an ounce;* Nutmeg *a drachm;* Sugar *six ounces.* Rub them separately into powder; then mix them, and with water form them into a mass, to be divided into troches, each weighing ten grains." *U.S.* "Powder them together, and form them with water into a mass fit for making troches." *Ed.*

These are used as a gently astringent antacid in diarrhœa. W.

TROCHISCI GLYCYRRHIZÆ ET OPII. *U.S.* TROCHISCI GLYCYRRHIZÆ CUM OPIO. *Ed.* *Troches of Liquorice and Opium.*

"Take of Opium *two drachms;* Tincture of Tolu *half a fluidounce;* Syrup *half a pint;* Liquorice [extract], softened by hot water, Gum Arabic, in powder, each, *five ounces.* Rub the Opium thoroughly with the Tincture; then gradually add, first the Syrup and Extract, and afterwards the Gum, mixing them well together; lastly, dry the mass, and divide it into troches, each weighing ten grains." *U.S.*

The *Edinburgh College* directs half an ounce (by weight) of tincture of balsam of tolu, and eight ounces (by weight) of simple syrup. In other respects, the process is the same with the above.

In regard to these troches, Dr. Duncan, in his Dispensatory, states that "they are more easily prepared, and the uniform diffusion of the opium is more certainly attained, by previously drying and reducing to powder the opium and liquorice, which are to be intimately mixed with the powdered gum Arabic. This is to be beat into a mass first with the tincture, and then the syrup, and if necessary a little water gradually added." A preparation equivalent to the above is much used in Philadelphia under the name of *Wistar's cough lozenges.* A little oil of aniseed or oil of caraway is usually mixed with the other ingredients; but this addition, unless in very minute proportion, though it improves the flavour, interferes with the demulcent virtues of the preparation.

These troches are demulcent and anodyne, and very useful in allaying cough, when the state of the case admits the employment of opium, of which each of them contains about one-seventh of a grain. W.

TROCHISCI GLYCYRRHIZÆ GLABRÆ. *Ed.* *Troches of Liquorice.*

"Take of Extract of Liquorice, Gum Arabic, each, *one part;* Refined Sugar *two parts;* Boiling Water *a sufficient quantity.* Dissolve and strain; then evaporate the solution, by a gentle fire, to the consistence proper for forming troches." *Ed.*

These troches are useful in allaying cough, but are seldom employed; having been superseded by refined liquorice, which answers the same purpose, without being so cloying to the palate. W.

TROCHISCI GUMMOSI. *Ed.* *Gum Troches.*

"Take of Gum Arabic *four parts;* Starch *one part;* Refined Sugar *twelve parts.* Powder them, and with Rose Water make a mass fit for the formation of troches." *Ed.*

These are useful in allaying the irritation of the fauces which excites coughing, and may be employed at pleasure. W.

TROCHISCI MAGNESIÆ. *U.S.* *Troches of Magnesia.*

"Take of Magnesia *four ounces;* Gum Arabic *an ounce;* Nutmeg *a drachm;* Sugar *six ounces.* Prepare the Troches of Magnesia in the manner directed for those of Carbonate of Lime." *U.S.*

TROCHISCI CARBONATIS MAGNESIÆ. *Ed.* *Troches of Carbonate of Magnesia.*

"Take of Carbonate of Magnesia *six ounces;* Refined Sugar *three ounces;* Nutmeg *a scruple.* Powder them, and with Mucilage of Tragacanth make a mass fit for the formation of troches." *Ed.*

These and the preceding troches are useful in acidity of stomach, especially when attended with constipation. W.

TROCHISCI NITRATIS POTASSÆ. *Ed.* *Troches of Nitrate of Potassa.*

"Take of Nitrate of Potassa *one part;* Refined Sugar *three parts.* Powder them, and with Mucilage of Tragacanth make a mass fit for forming troches." *Ed.*

These troches, held in the mouth and allowed slowly to dissolve, form a cooling application in excessive salivation; and are useful in the incipient stages of inflammation of the throat. For internal use, the nitre is more conveniently taken in the form of powder or solution. W.

UNGUENTA.

Ointments.

These are fatty substances, softer than cerates, of a consistence resembling that of butter, and such that they may be readily applied to the skin by inunction. Many of them become rancid when long kept, and should, therefore, be prepared in small quantities at a time, or only when wanted for use. W.

UNGUENTUM ACIDI NITROSI. *Ed.* *Ointment of Nitrous Acid.*

"Take of Lard *a pound;* Nitrous Acid *six drachms.* Mix the Acid gradually with the melted Lard, and beat the mixture assiduously as it cools." *Ed.*

If the mixture be kept for a short time on the fire, it becomes of a yellow colour, and emits fumes of nitrous acid. The lard is oxidized at the expense of a portion of the acid, and combines with the remainder, assuming a firm consistence when it cools. The ointment thus prepared was originally employed by Alyon, under whose name it passes on the continent of Europe. It is useful in syphilitic ulcers, and in eruptive complaints, particularly psora and the different forms of porrigo; but it has been superseded by the ointment of nitrate of mercury, which is more efficient. W.

UNGUENTUM ACIDI NITRICI. *Dub.* *Ointment of Nitric Acid.*

"Take of Olive Oil *a pound;* Prepared Lard *four ounces;* Nitric Acid *five and a half fluidrachms.* Melt the Oil and Lard together in a glass vessel, and when they begin to congeal, add the Acid, and stir the mixture constantly with a glass rod till it stiffens." *Dub.*

This ointment possesses the same properties, and is used for the same purposes, as the preceding. W.

UNGUENTUM ACIDI SULPHURICI. *Dub.* *Ointment of Sulphuric Acid.*

"Take of Sulphuric Acid *a drachm;* Prepared Lard *an ounce.* Mix them." *Dub.*

In this process the acid is partly converted into sulphurous acid which escapes, and a portion of the lard is charred. The ointment is dark-coloured and fetid. It was a favourite application with Dr. Duncan, Senr. in scabies, and we have found it effectual in the same complaint. It may also be used with advantage in other eruptive affections, particularly ringworm. W.

UNGUENTUM AQUÆ ROSÆ. *U.S. Ointment of Rose Water.*

"Take of Rose Water, Oil of Almonds, each, *two fluidounces;* Spermaceti *half an ounce;* White Wax *a drachm.* Melt together, by means of a water-bath, the Oil, Spermaceti, and Wax; then add the Rose Water, and stir the mixture constantly until it is cold." *U.S.*

This preparation is much employed under the name of *cold cream.* It is a white, very soft, and elegant unguent, deriving a grateful odour from the rose water, which remains incorporated with the other constituents if kept enclosed in glazed vessels. It is a pleasant, cooling application to irritated and excoriated surfaces; and may be used with great advantage for chapped lips and hands so frequent in cold weather. W.

UNGUENTUM CANTHARIDIS. *U.S., Lond., Dub. Ointment of Spanish Flies.*

"Take of Spanish Flies, in powder [very fine powder, *Lond., Dub.*], *two ounces;* Distilled Water *half a pint;* Resin Cerate *eight ounces.* Boil down the Water with the Spanish Flies to one half, and strain; then mix the Cerate with the strained liquor, and evaporate to a proper consistence." *U.S., Lond., Dub.*

By this process, the active matter of the flies is more uniformly diffused through the ointment, than when they are directly incorporated, in the state of powder, with the other ingredients. The preparation is thus better calculated to meet the end proposed, of maintaining the discharge from blistered surfaces, without producing undue irritation. It is said that the virtues of the flies are impaired by the boiling; but experience has shown that considerable activity remains. It is necessary, after the strained decoction and cerate have been mixed, to stir constantly during the remainder of the process, in order to prevent the former from sinking to the bottom. It should be recollected, that this ointment is intended as a dressing for blisters, not to produce vesication. W.

UNGUENTUM INFUSI CANTHARIDIS VESICATORIÆ. *Ed. Ointment of infusion of Spanish Flies.*

"Take of Spanish Flies, White Resin, Yellow Wax, each, *one part;* Lard, Venice Turpentine, each, *two parts;* Boiling Water *four parts.* Macerate the Spanish Flies in the water for a night, and having strained the liquor with strong expression, boil it with the Lard till the water is evaporated; then add the Resin and Wax, and when these are melted, remove the mixture from the fire, and add the Turpentine." *Ed.*

This ointment differs from the preceding only in containing Venice turpentine, which increases its stimulant properties. W.

UNGUENTUM PULVERIS CANTHARIDIS VESICATORIÆ. *Ed.* CERATUM CANTHARIDIS. *Lond. Ointment of the Powder of Spanish Flies.*

"Take of Resin Ointment *seven parts;* Spanish Flies, in very fine powder, *one part.* Sprinkle the powder into the melted ointment, and stir the mixture constantly till it stiffens on cooling." *Ed.*

"Take of Spanish Flies, in very fine powder, *a drachm;* Spermaceti Cerate *six drachms.* To the Cerate softened by heat, add the Flies, and mix." *Lond.*

This ointment, like the two preceding, is intended as a dressing for blistered surfaces, with a view to maintain the discharge. The flies should be very finely powdered, in order that they may be diffused as uniformly as possible through the mass. It is unfortunate that the term *ceratum cantharidis* has been conferred upon this preparation by the London College, as the same name is properly employed in the U.S. Pharmacopœia to express the preparation of flies intended to be used as a vesicatory. None of these ointments can be used in individuals liable to strangury from the external application of cantharides. W.

UNGUENTUM CETACEI. *Lond.* *Spermaceti Ointment.*

"Take of Spermaceti *six drachms;* White Wax *two drachms;* Olive Oil *three fluidounces.* Melt them together over a slow fire, and stir them constantly until cold." *Lond.*

This ointment is employed as a mild dressing for blisters, wounds, and excoriated surfaces. It should be made in small quantities at a time, as it is apt to become rancid when long kept. W.

UNGUENTUM CONII. *Dub.* *Ointment of Hemlock.*

"Take of fresh Hemlock Leaves, Prepared Lard, each *two pounds.* Boil the Leaves in the Lard till they become crisp, and then express through linen." *Dub.*

The narcotic principle of fresh hemlock is extracted by lard with the aid of heat. The resulting ointment may be advantageously used, as an anodyne application to irritable piles, painful glandular swellings and scirrhous tumours, and to cancerous and other painful ulcers. W.

UNGUENTUM CUPRI ACETATIS. *U.S.* UNGUENTUM SUBACETATIS CUPRI. *Ed.* UNGUENTUM CUPRI SUBACETATIS. *Dub.* *Ointment of Acetate of Copper.*

"Take of Prepared Acetate of Copper, in powder, *an ounce;* Simple Ointment *fifteen ounces.* Add the Acetate of Copper to the Ointment previously melted over a gentle fire, and stir them constantly until they are cold." *U.S.*

"Take of Resinous Ointment [resin cerate] *fifteen parts;* Sub-Acetate of Copper, in very fine powder, *one part.* Sprinkle the Sub-Acetate into the melted Ointment, and stir the mixture till it stiffens upon cooling." *Ed.*

"Take of Prepared Subacetate of Copper *half an ounce;* Olive Oil *an ounce;* Ointment of White Resin [resin cerate] *a pound.* Rub the Subacetate with the oil; then add them to the Ointment previously melted, and mix." *Dub.*

This ointment is employed as a mild escharotic in fungous granulations, and, more or less diluted with lard, as a stimulating application to foul and flabby ulcers, scrofulous ulcerations of the edges of the eyelids, disease of the external meatus of the ear with purulent discharge, and to certain cutaneous eruptions, particularly that form of porrigo denominated *ringworm of the scalp.* W.

UNGUENTUM ELEMI. *Dub.* *Ointment of Elemi.*

"Take of Resin of Elemi *a pound;* White Wax *half a pound;* Prepared Lard *four pounds.* Make an ointment, and strain it through a sieve while hot." *Dub.*

UNGUENTUM ELEMI COMPOSITUM. *Lond.* *Compound Ointment of Elemi.*

"Take of Elemi *a pound;* Common Turpentine *ten ounces;* Prepared Suet *two pounds;* Olive Oil *two fluidounces.* Melt the Elemi with the Suet, and having removed them from the fire, immediately mix with them the Turpentine and Oil, and express through linen." *Lond.*

This ointment is employed as a gentle stimulant to weak ulcers, and may be used for maintaining the discharge of issues and setons. It is the *linimentum arcæi* of the older pharmacy. W.

UNGUENTUM GALLÆ. *U.S.* UNGUENTUM GALLARUM. *Dub.* *Ointment of Galls.*

"Take of Galls, in powder [very fine powder, *Dub.*], *an ounce;* Lard *seven ounces* [eight ounces, *Dub.*]. Mix them." *U.S., Dub.*

This is used chiefly in piles and prolapsus ani, though it may also be advantageously applied to indolent ulcers. To obviate the pain which it is liable to produce in irritable hemorrhoids, it is sometimes combined with powdered opium, in the proportion of a drachm of the powder to an ounce of ointment; but, thus modified, it requires to be used with caution. W.

UNGUENTUM HYDRARGYRI. *U.S., Ed., Dub.* UNGUENTUM HYDRARGYRI FORTIUS. *Lond.* *Mercurial Ointment. Strong Mercurial Ointment.*

"Take of Purified Mercury *two pounds;* Lard *twenty-three ounces;* Suet *an ounce.* Rub the Mercury with the Suet and a small portion of the Lard till the globules disappear; then add the remainder of the Lard, and mix." *U.S., Lond.*

"Take of Purified Mercury, Suet, each, *one part;* Lard *three parts.*—Rub the Mercury diligently in a mortar, with a little of the Lard, until the globules entirely disappear; then add the remainder of the fats. This Ointment may also be made with double or triple the quantity of Mercury." *Ed.*

"Take of Purified Mercury, prepared Lard, *equal weights.* Rub them together in a marble or iron mortar, till the globules of mercury disappear." *Dub.*

UNGUENTUM HYDRARGYRI MITIUS. *Lond., Dub.* *Mild Mercurial Ointment.*

"Take of Strong Mercurial Ointment *a pound;* Prepared Lard *two pounds.* Mix them." *Lond.*

The *Dublin College* prepares this ointment with twice the quantity of lard used in the preparation of the stronger ointment.

The U.S. Pharmacopœia directs only one mercurial ointment, which accords in strength with the strongest ointment of the London and Dublin Colleges, containing equal weights of mercury and fatty matter. When the physician wishes a weaker preparation, he may direct the ointment to be diluted with such a proportion of lard as may answer his purposes. The ointment of the Edinburgh College contains one part of mercury and four of fat, and may also be prepared with two parts, or three parts of the former; but even when strongest, it is not equal to our officinal ointment. The milder ointment of the London College contains one part of mercury to five of fat, that of the Dublin College, one of the former to two of the latter. If the apothecary keep a milder preparation in his shop, it should be that of the London College, which, from the smaller proportion of mercury, is preferable to that of the Dublin College for the purposes to which the milder ointment is usually applied. It should always be understood that the stronger ointment is intended by the physician, unless the contrary is expressly stated.

In the preparation of the mercurial ointment, care is requisite that the mercury should be completely extinguished. The trituration is best performed in a marble mortar, as it is difficult to keep iron so clean as not to impart more or less oxide to the ointment. The mercury is known to be extinguished, when a portion of the mass, rubbed upon paper or the back of the hand, exhibits no metallic globules. To facilitate the process, which is very tedious, the addition of various substances has been proposed, calculated to hasten the disappearance of the metal. Turpentine and sulphur have been employed for this purpose, but are both inadmissible, the former because it renders the ointment too irritating, the latter because it forms with the mercury an inactive sulphuret. Their presence in the ointment may be detected by the peculiar odour which they respectively emit when exposed to heat. Sulphur, moreover, gives the ointment a darker colour than it has when pure. Rancidity in the lard employed, also facilitates the extinguishment of the mercury, but is liable to the same objection as turpentine. M. Planche has proposed the oil of eggs; but M. Guibourt did not find it more effectual than fresh lard. The latter pharmaceutist recommends the addition of one-sixteenth of old mercurial ointment, which experience has shown to be very useful in promoting the thorough mixture of the mercury and lard, and which is liable to no practical objection. The following plan of preparing the ointment has been proposed by M. Chevallier. Having taken a pound of mercury and the same quantity of fresh lard, he introduces the metal with half the lard previously melted into a stone or glass bottle, shakes the mixture till it acquires the consistence of very thick syrup, then pours it into a mortar, and adds the remainder of the lard, stirring constantly. In this manner, according to Chevallier, a perfect ointment may be made in half an hour. But when prepared with lard alone, the ointment is apt, in hot weather, to become so soft as to allow the metal to separate. Hence the addition of suet in the processes of the U.S. and London Pharmacopœias; and even a larger proportion, as directed by the Edinburgh College, might be employed when the ointment is prepared for use in the summer season.

Mercurial ointment has when newly prepared a bluish colour, which becomes darker by age. It was formerly thought to contain the mercury in the state of protoxide; but it has been shown that most if not all of the metal can be separated from the lard by methods not calculated to reduce the oxide; and chemists now generally admit that it exists in the preparation in a state of minute division, not of chemical combination. Some, however, still maintain that the metal is partially oxidized; and the darker colour which the ointment acquires by age is attributed to the further oxidizement of the mercury. Mr. Donovan considers the common mercurial ointment as consisting partly of uncombined metal and lard, and partly of a chemical compound of the protoxide and lard; and to the latter portion alone he attributes its medicinal activity. A mixture of lard and the black oxide has not the same effect, because there is no chemical union between the ingredients, and this union, in his opinion, is necessary to the absorption of the mercurial. Upon exposing such a mixture to a temperature of 350° F. and continually agitating it for two hours, he found that every ounce of lard dissolved and combined with twenty-one grains of oxide; and the resulting compound was found to be equally effectual with the common ointment, and capable of being introduced into the system in one-third of the time. (Paris's Pharmacologia.) It has been proposed to substitute an ointment thus prepared for that made according to the officinal directions, as being more manageable, and of more uniform strength. In its preparation, care is requisite not to employ too high nor too low a temperature; as the former decomposes the oxide, and the latter is insufficient to effect its union with the lard.

Mercurial ointment, when rubbed upon the surface of the body, produces, in consequence of its absorption, the same general effects upon the system as the other preparations of the metal. It is resorted to either alone, when circumstances prevent or discourage the internal use of mercury, or conjointly with the internal use of the medicine, to produce a more speedy or powerful effect in urgent cases. It may also be advantageously employed as a resolvent in local affections, as in the case of venereal buboes, and of chronic glandular swellings, upon which it may be made to operate directly by being applied in the course of the absorbents which pass through the enlarged glands. The proper quantity to be employed atone time, with a view to salivation, is about a drachm, which should be applied night and morning, by means of friction, to the inner surface of the thighs, legs, or arms, and continued till the system is affected.

In urgent cases, or in local affections, it may also be rubbed on other parts of the body, or applied to blistered surfaces. The friction should on each occasion be continued till the whole of the ointment is absorbed. When frequently rubbed upon the same part, it is apt to produce a disagreeable eruption which interferes with its continued application. Camphor is sometimes added in order to render it more easy of absorption; but, without producing this effect, it increases the liability of the ointment to irritate the skin, and is of no other advantage than to soften its consistence, when too firm from a large proportion of suet.

The weaker ointment is employed only as an application to ulcers, and to certain cutaneous eruptions. W.

UNGUENTUM HYDRARGYRI AMMONIATI. *U.S.* UNGUENTUM HYDRARGYRI PRÆCIPITATI ALBI. *Lond.* UNGUENTUM HYDRARGYRI SUBMURIATIS AMMONIATI. *Dub.* *Ointment of Ammoniated Mercury. Ointment of White Precipitate.*

"Take of Ammoniated Mercury *an ounce;* Simple Ointment *eight ounces.* Add the Ammoniated Mercury to the Ointment previously softened over a gentle fire, and mix them." *U.S.*

The *London* and *Dublin Colleges* employ a drachm of the ammoniated mercury, and an ounce and a half of lard, and proceed as above.

This ointment is employed chiefly in cutaneous eruptions, such as psora, porrigo, and herpes. W.

UNGUENTUM HYDRARGYRI NITRATIS. *U.S., Lond.* UNGUENTUM NITRATIS HYDRARGYRI FORTIUS. *Ed.* UNGUENTUM HYDRARGYRI NITRATIS vel UNGUENTUM CITRINUM. *Dub.* *Ointment of Nitrate of Mercury. Citrine Ointment.*

"Take of Purified Mercury *an ounce;* Nitric Acid *eleven fluidrachms;* fresh Neats-foot Oil *nine fluidounces;* Lard *three ounces.* Dissolve the Mercury in the Acid; then melt the Oil and Lard together, and when they begin to stiffen [upon cooling], add the solution, and mix them." *U.S.*

"Take of Purified Mercury *an ounce;* Nitric Acid *eleven fluidrachms;* Prepared Lard *six ounces;* Olive Oil *four fluidounces.* First dissolve the Mercury in the Acid; then, while the solution is hot, mix it with the Lard and Oil previously melted together." *Lond.*

"Take of Purified Mercury *one part;* Nitrous Acid *two parts;* Olive Oil *nine parts;* Lard *three parts.* Dissolve the Mercury in the Acid; then beat up the solution strongly with the Lard and Oil when nearly stiff after having been melted together." *Ed.*

"Take of Purified Mercury *an ounce;* Nitric Acid *eleven drachms and a half;* Olive Oil *a pint;* Prepared Lard *four ounces.* Dissolve the Mercury in the Acid, then mix the solution with the Oil and Lard previously melted together, and form an ointment, in the manner directed for the Ointment of Nitric Acid." *Dub.*

This ointment should be prepared in a glass, porcelain, or well glazed earthenware vessel. Dr. A. T. Thomson says that "the addition of the metallic solution to the melted mixture of lard and oil should be gradual, and made in a broad flat vessel; while the stirring should be performed by a wooden spatula, and continued till the ointment be perfectly cool."

When recently prepared, the ointment has a beautiful yellow colour and a soft consistence, which, however, it is apt to lose by time, acquiring a dirty greenish hue, and becoming so hard and friable as to be unfit for application unless mixed with lard. This change has been attributed by some to the use of too large a proportion of lard, which, they say, is oxidized and hardened by the excess of acid. According to Dr. A. T. Thomson, the ointment, when prepared with only one-sixth of its weight of lard, retains its colour and consistence, if preserved in close pots, while with a larger proportion "it becomes hard, brittle, and of a pale dirty yellow hue, marbled with green blotches." This, however, is a mistake. It is the olive oil which is hardened by the supernitrate of mercury, and the ointment is firmer when made with that oil alone than with a proportion of lard. Hence, in the last edition of the U. S. Pharmacopœia, neatsfoot oil has been substituted for that of the olive, and with decided advantage. We had in our possession upwards of four months, a pot of ointment made according to the process of the Pharmacopœia, and, though it had, at the end of this time, partially assumed a greenish colour, it preserved a uniform, soft, unctuous consistence. It was prepared with nitric acid of the sp. gr. 1.335.*

Under the impression that the deterioration of the ointment is owing to the oxidizement of the oleaginous ingredients by the excess of nitric acid, it has been recommended to prepare it with a diminished quantity of acid, and at as low a temperature as possible. But this plan has not been found to answer the end in view. The following formula, which, Dr. Duncan informs us, yields the most perfect citrine ointment which he had seen, preserving a fine golden colour, and the requisite softness, is in direct opposition to formerly received notions. It was originally employed by Mr. Duncan of Edinburgh. "Take of nitrous acid twelve ounces, mercury four ounces, olive oil twenty-six and a half ounces, lard fifteen ounces; dissolve the mercury in the acid, and pour the solution while still hot into the lard melted in the oil, and also still hot, and mix in a vessel capable of containing five times the quantity, as a violent effervescence takes place. If it should not froth up, the action must be assisted by heat." In relation to this process, we quote the following observations from the Edinburgh Dispensatory. "The differences between this and the officinal formulæ are the much larger proportion of acid employed, and the higher temperature applied at the time of the mixture of the mercurial solution with the oily substances. The violent effervescence probably arises from a disengagement of nitric oxide, and it would appear that the rapid oxygenizement did not harden the oily substances so much as a slower change, and that a higher oxygenizement of the nitrate of mercury prevented its decomposition and gradual conversion into the state of protoxide, on which the slate colour of the officinal ointment, when long kept, probably depends. Mr. Duncan now prepares it entirely with lard, and it preserves equally the desired colour and consistence."

---

* See "Remarks on the preparation of Citrine Ointment, by W. R. Fisher," in the Journ. of the Philadelphia College of Pharmacy, i. 171. It is said that the three ounces of lard directed in the U. S. formula may be advantageously dispensed with, and its place supplied by three additional fluidounces of the neats-foot oil. See the same Journal, iv. 197.

Medical Uses. This ointment is much and very advantageously employed, as a stimulant and alterative application, in various forms of porrigo, as tinea capitis and crusta lactea, in psoriasis and ptyriasis, in certain forms of herpes, in psorophthalmia and inflammation of the eye and eyelids connected with porrigo of the face or scalp, and in various other ulcerative and eruptive affections. It should be diluted with lard, unless in cases which require a very stimulant application. Some care is requisite in its use, to avoid the risk of salivation. When hard and friable, it must be rubbed up with fresh lard before it can be applied. W.

UNGUENTUM NITRATIS HYDRARGYRI MITIUS. *Ed.* *Milder Ointment of Nitrate of Mercury.*

"This is prepared in the same manner as the stronger ointment, with three times the quantity of Oil and Lard." *Ed.*

This is a useless preparation, as it can answer no other purpose than a mixture of the stronger ointment with lard. W.

UNGUENTUM OXIDI HYDRARGYRI CINEREI. *Ed.* *Ointment of Gray Oxide of Mercury.*

"Take of Gray Oxide of Mercury *one part;* Lard *three parts.* Mix them thoroughly." *Ed.*

This was intended to supply the place of the mercurial ointment, as a means of introducing mercury into the system by friction; but it has not stood the test of experience, and is therefore little employed. It is said that the oxide of mercury is not absorbed with the lard. Dr. Paris conjectures, upon the foundation of Mr. Donovan's experiments, (see *Unguentum Hydrargyri,*) that if subjected for some hours to a heat of 300°, it would become active, in consequence of the occurrence of a chemical union between the ingredients, which would enable the mercurial to be taken up by the absorbents. W.

UNGUENTUM HYDRARGYRI OXIDI RUBRI. *U.S.* UNGUENTUM HYDRARGYRI NITRICO-OXYDI. *Lond.* UNGUENTUM OXIDI HYDRARGYRI RUBRI. *Ed.* UNGUENTUM HYDRARGYRI OXYDI NITRICI. *Dub.* *Ointment of Red Oxide of Mercury.*

"Take of Red Oxide of Mercury, in very fine powder, *an ounce;* Simple Ointment *eight ounces.* Add the Oxide of Mercury to the Ointment previously softened over a gentle fire, and mix them." *U.S.*

"Take of Nitric Oxide of Mercury *an ounce;* White Wax *two ounces;* Prepared Lard *six ounces.* To the Wax and Lard, melted together, add the Nitric Oxide of Mercury, in very fine powder, and mix." *Lond., Dub.*

"Take of Red Oxide of Mercury by Nitric Acid, in very fine powder, *one part;* Lard *eight parts.* Mix them thoroughly." *Ed.*

The U.S. Pharmacopœia contemplates the same red oxide of Mercury as the British Colleges, that, namely, prepared from the nitrate, and usually called *red precipitate.*

This ointment loses its fine red colour when long kept, probably in consequence of the conversion of the red oxide into the black. It is best to prepare it only in small quantities at a time. It is a highly useful stimulating ointment, much employed in indolent and foul ulcers, in porrigo of the scalp, and in chronic conjunctival ophthalmia, especially when attended with thickening of the inner membrane of the eyelids, or with specks upon the cornea. It may be diluted with lard if found too stimulating. W.

UNGUENTUM IODINII. *Dub.* *Ointment of Iodine.*

"Take of Iodine *a scruple;* Prepared Lard *an ounce.* Rub them together so as to form an ointment." *Dub.*

This ointment, when rubbed upon the skin, imparts to it an orange colour, which, however, slowly disappears with the evaporation of the iodine. It is useful as a local application in goitre and scrofulous swellings of the glands, operating probably through the medium of absorption. When continued for some time, it occasionally produces a pustular eruption upon the portion of skin to which it is applied. W.

UNGUENTUM PICIS NIGRÆ. *Lond.* *Ointment of Pitch.*

"Take of Pitch, Yellow Wax, Yellow Resin, each, *nine ounces;* Olive Oil *a pint.* Melt them together, and strain throngh linen." *Lond.*

This is a stimulant ointment, applicable to the same purposes with the following.

UNGUENTUM PICIS LIQUIDÆ. *U.S.*, *Lond.* *Ed.*, *Dub.* *Tar Ointment.*

"Take of Tar, Suet, each, *a pound.* Add the Tar to the Suet previously melted over a gentle fire, and stir them constantly till they are cold." *U. S.*

The *London* and *Dublin Colleges* melt together equal parts of the tar and suet, and strain the mixture, the former through linen, the latter through a sieve. The *Edinburgh College* takes five parts of tar and two parts of yellow wax, and having melted the wax with a gentle heat, adds the pitch, and stirs constantly till the mixture stiffens.

Tar ointment is highly useful as a stimulant application in various scabby eruptions, particularly in that form of porrigo usually called tinea capitis or scald head. It should be applied night and morning; and in bad cases the patient should constantly wear a cap thickly spread with the ointment upon its internal surface. W.

UNGUENTUM PIPERIS NIGRI. *Dub.* *Ointment of Black Pepper.*

"Take of Prepared Lard *a pound;* Black Pepper, in powder, *four ounces.* Make an ointment." *Dub.*

This is highly irritating, and has been used as a remedy in tinea capitis, but is not now employed. W.

UNGUENTUM PLUMBI ACETATIS. *Dub.* CERATUM PLUMBI ACETATIS. *Lond.* UNGUENTUM ACETATIS PLUMBI. *Ed.* *Ointment of Acetate of Lead.*

"Take of Simple Ointment *twenty parts;* Acetate of Lead, in very fine powder, *one part.* Mix them thoroughly." *Ed.*

The *Dublin College* mixes an ounce of acetate of lead with a pound and a half of ointment of white wax. The *London College* melts two ounces of wax in seven fluidounces of olive oil; then adds two drachms of acetate of lead previously rubbed with a fluidounce of oil; and stirs with a wooden spatula till they are mixed.

This is an excellent ointment in burns, and iu other excoriated or ulcerated surfaces, particularly blisters in an inflamed state. W.

UNGUENTUM PLUMBI CARBONATIS. *U.S.*, *Dub.* UNGUENTUM CARBONATIS PLUMBI. *Ed.* *Ointment of Carbonate of Lead.*

"Take of Carbonate of Lead, in very fine powder, *two ounces;* Simple Ointment *a pound.* Add the Carbonate of Lead to the Ointment previously softened over a gentle fire, and mix them." *U. S.*

The *Edinburgh College* prepares this ointment by mixing thoroughly one part of carbonate of lead with five parts of simple ointment. The *Dublin College* employs the same proportions with the U.S. Pharmacopœia.

This ointment is used for the same purposes as the preceding. W.

UNGUENTUM POTASSÆ HYDRIODATIS. *Dub. Ointment of Hydriodate of Potassa.*

"Take of Hydriodate of Potassa [Iodide of Potassium] *a scruple;* Prepared Lard *an ounce.* Rub them together so as to form an ointment." *Dub.*

This is employed for the discussion of goitres, scrofulous tumours, and other indolent swellings; and is usually preferred to the ointment of iodine, as it does not like that discolour the skin. It is probably, however, of inferior virtue, and certainly contains too small a proportion of the iodide. One drachm to the ounce of lard would not be too much, and may sometimes be exceeded. W.

UNGUENTUM SAMBUCI. *Lond., Dub. Elder Ointment.*

"Take of Elder Flowers, Prepared Lard, each, *two pounds.* Boil the Elder Flowers in the Lard till they become crisp, then express through linen." *Lond.*

"Take of fresh Elder Flowers *three pounds;* Prepared Lard *four pounds;* Prepared Mutton Suet *two pounds.* Boil the Flowers in the Lard till they become crisp; then strain with expression; lastly, add the Suet, and melt them together." *Dub.*

Elder flowers impart odour to lard without adding to its virtues. W.

UNGUENTUM SCROPHULARIÆ. *Dub. Ointment of Figwort.*

"Take of fresh Figwort Leaves, Prepared Lard, each, *two pounds;* Prepared Mutton Suet *a pound.* Boil the Leaves in the fat till they become crisp, then strain with expression." *Dub.*

For the properties of this ointment, see *Scrophularia Nodosa.* W.

UNGUENTUM SIMPLEX. *U.S., Ed.* UNGUENTUM CERÆ ALBÆ. UNGUENTUM CERÆ FLAVÆ. *Dub. Simple Ointment.*

"Take of White Wax *a pound;* Lard *four pounds.* Melt them together with a gentle heat, and stir them constantly till they are cold." *U.S.*

The *Edinburgh College* orders five parts of olive oil and two parts of white wax. The *Dublin College* makes two preparations, one with white, the other with purified yellow wax, in each case mixing the wax with lard in the same proportion as directed in the U. S. Pharmacopœia.

This is a useful emollient ointment, occasionally employed as a mild dressing to blistered or excoriated surfaces, but more frequently as a vehicle for the application of more active substances. It is the basis of several officinal ointments. W.

UNGUENTUM STRAMONII. *U.S. Ointment of Thorn-apple.*

"Take of fresh Thorn-apple Leaves, cut in pieces, *a pound;* Lard *three pounds;* Yellow Wax *half a pound.* Boil the Thorn-apple Leaves in the Lard, till they become friable; then strain through linen; lastly, add the Wax previously melted, and stir them till they are cold." *U.S.*

Fresh narcotic vegetables yield their active principles, and chlorophylle or green colouring matter, to oleaginous substances, when heated with them; and several officinal ointments besides the present are prepared in this manner. In the pharmacy of the continent of Europe, olive oil is frequently employed as the solvent; and the resulting preparations are called *olea infusa.* Several of these are ordered by the Paris Codex, as the oils of henbane, thorn-apple, tobacco, &c. Lard is preferred in British and American Pharmacy, as affording preparations of a more convenient consistence. The boiling takes place at a lower temperature than that necessary for the evaporation of the lard or oil, and is owing to the escape of the watery parts of the plants. It should be continued till all the water is driven off; as this, if allowed to remain, will render the ointment more liable to spontaneous decomposition; and, besides, the colouring matter of the narcotic is not freely extracted till after the dissipation of the water.

The ointment of stramonium is a useful anodyne application in irritable ulcers, in painful hemorrhoids, and in some cntaneous eruptions. W.

UNGUENTUM SULPHURIS. *U.S., Lond., Ed., Dub. Sulphur Ointment.*

"Take of Sulphur *a pound;* Lard *four pounds.* Mix them." *U.S.*

The *London College* employs three ounces of sublimed sulphur and half a pound of lard; the *Edinburgh* and *Dublin Colleges*, the same proportion as directed in the U. S. Pharmacopœia.

Sulphur ointment is a specific for the itch. It should be applied every night till the complaint is cured; and it is recommended that only one-fourth of the body should be covered at a time. We have usually directed it to be applied over the whole surface, and have found no inconvenience to result. Four applications are usually sufficient to effect a cure. It is thought by some that powdered roll sulphur is more efficacious than the sublimed. The disagreeable odour of the ointment may be in some measure concealed by a little oil of lemons. W.

UNGUENTUM SULPHURIS COMPOSITUM. *U.S., Lond. Compound Sulphur Ointment.*

"Take of Sulphur *an ounce;* Ammoniated Mercury, Benzoic Acid, each, *a drachm;* Oil of Lemons, Sulphuric Acid, each, *a fluidrachm;* Nitrate of Potassa *two drachms;* Lard *half a pound.* To the Lard previously melted over a gentle fire add the other ingredients, and stir them constantly till they are cold." *U.S.*

This ointment is essentially different from that which is directed, under the same name, by the *London College.* Though, perhaps, not more efficient than the simple sulphur ointment in the cure of itch, it has a less unpleasant smell, and may be advantageously applied to the cure of other eruptive affections, such as tinea capitis and crusta lactea.

"Take of Sublimed Sulphur *half a pound;* White Hellebore Root, in powder, *two ounces;* Nitrate of Potassa *a drachm;* Soft Soap *half a pound;* Prepared Lard *a pound and a half.* Mix them." *Lond.*

This is thought to be more efficacious than the simple sulphur ointment; but the white hellebore renders it also more irritating. W.

UNGUENTUM TABACI. *U.S. Tobacco Ointment.*

"Take of fresh Tobacco, cut in pieces, *an ounce;* Lard *a pound.* Boil the Tobacco in the Lard over a gentle fire till it becomes friable; then strain through linen." *U.S.*

In the former edition of the U. S. Pharmacopœia, this ointment, under the name of "Tobacco Liniment," was directed to be prepared with common dried tobacco; but in this condition the leaves do not yield their virtues to lard. The error was corrected in the last edition. Though the tobacco plant is not an object of general culture in the Northern States, it may readily be produced in gardens, in quantities sufficient to supply any demand for the fresh leaves which can possibly arise. The remarks made under the head of *Unguentum Stramonii*, in relation to the preparation of ointments from the fresh narcotics, are applicable in this instance.

Tobacco ointment is useful in irritable ulcers, and various cutaneous eruptions, particularly *tinea capitis;* but great care must be taken, especially in infants, not to employ it in such quantities as to endanger the production of the constitutional effects of the narcotic. W.

UNGUENTUM TARTARI EMETICI. *Dub.* *Tartar Emetic Ointment.*

"Take of Tartrate of Antimony and Potassa *a drachm;* Prepared Lard *an ounce.* Rub the Salt into a very fine powder; then mix it with the Lard." *Dub.*

This may be more conveniently prepared with *simple ointment*, as lard is too soft to be spread on linen, and simple ointment is sufficiently so to be applied by inunction.

The peculiar eruptive effect of tartar emetic may be procured in various ways, either by means of a strong solution, or of the powder sprinkled upon the surface of some adhesive plaster, or of the ointment as above directed. The last method is, perhaps, the most convenient, and most generally resorted to. The proportion of tartar emetic may sometimes be advantageously increased to two or even three drachms, when a speedy effect is required, or the skin is not very susceptible to its action. A small portion of the ointment may be rubbed twice a day, or more frequently, upon the surface to be affected, or it may be applied spread upon a piece of linen. Care should be taken that the cuticle be entire, and that the application be not too long continued, as otherwise very severe inflammation, and even gangrenous ulceration, may result. We have, however, in some instances, of great urgency, applied the ointment to a surface recently scarified in the operation of cupping; but under such circumstances, it should be used with much caution. W.

UNGUENTUM VERATRI ALBI. *U.S.* UNGUENTUM VERATRI. *Lond.*, *Dub.* *Ointment of White Hellebore.*

"Take of White Hellebore [root], in powder, *two ounces;* Oil of Lemons *twenty minims;* Lard *eight ounces.* Mix them." *U.S.*, *Lond.*

The *Dublin College* employs the same proportion of white Hellebore and lard, but omits the oil of lemons.

This ointment is sometimes employed with advantage in the itch. It is less disagreeable, but also less certain than the sulphur ointment. W.

UNGUENTUM VERATRI VIRIDIS, *U.S.* *Ointment of American Hellebore.*

"Take of American Hellebore [root], in powder, *two ounces;* Oil of Lemons *twenty minims;* Lard *eight ounces.* Mix them." *U. S.*

This may be employed for the same purpose as the ointment of white hellebore.

UNGUENTUM ZINCI OXIDI. *U.S.* UNGUENTUM ZINCI. *Lond.* UNGUENTUM OXIDI ZINCI. *Ed.* UNGUENTUM ZINCI OXYDI. *Dub.* *Ointment of Oxide of Zinc.*

"Take of Oxide of Zinc *an ounce;* Lard *half a pound.* Mix them." *U.S.*, *Lond.*

The *Edinburgh College* employs six parts of simple liniment, and one of prepared oxide of zinc; the *Dublin*, one pound of ointment of white wax (simple ointment), and two ounces of the prepared oxide. In the latter case the ointment is melted before the addition of the oxide.

The oxide of zinc directed in the U.S. and London Pharmacopœias, is that obtained by precipitation, and, being in the state of fine powder, requires no previous preparation. That employed by the Edinburgh and Dublin Colleges, being procured by the combustion of the metal, requires to be levigated before it can be used for the formation of the ointment.

This preparation is employed as a mild astringent application in chronic ophthalmia with a relaxed state of the vessels, in various cutaneous eruptions, and in sore nipples and other instances of excoriation or ulceration. W.

UNGUENTUM OXIDI ZINCI IMPURI. *Ed.* *Ointment of Impure Oxide of Zinc.*

"Take of Simple Liniment *five parts;* Prepared Impure Oxide of Zinc *one part.* Mix them thoroughly." *Ed.*

This is the old *unguentum tutiæ*, or *tutty ointment.* It has been superseded in most of the Pharmacopœias by the last mentioned ointment, which is of a white instead of a gray colour, and is altogether a neater preparation. It is still, however, occasionally used in excoriations. W.

VINA MEDICATA.

Medicated Wines.

The advantages of wine as a pharmaceutic menstruum are, that, in consequence of the alcohol it contains, it dissolves substances insoluble in water, and, to a certain extent, resists their tendency to spontaneous change, while, at the same time, it is less stimulant than rectified or proof spirit, both from its smaller proportion of alcohol, and from the modified state in which this fluid exists in its composition. The acid which it usually contains, serves in some instances to increase its solvent power. But most wines, particularly the light varieties, are liable to undergo decomposition; and even the strongest acquire such a liability, from the principles which they extract from vegetable substances; so that medicated wines, though they keep much better than infusions or decoctions, are inferior in this respect to the tinctures. The proportion of alcohol, moreover, is not constant; and the preparations, therefore, made with them, are of unequal strength. From these causes, few medicated wines are at present retained. Indeed the London College has altogether discarded wine as a menstruum, and substituted in its place a mixture of water and proof spirit; still, however, retaining the title *vina* or *wines* for the preparations. We can see no advantage in this menstruum over wine of good quality, as, though of itself insusceptible of change, the substances which it dissolves serve as a ferment, and promote its decomposition. In the choice of wine, the purest and most generous should be selected. Teneriffe, as directed by the U.S. Pharmacopœia, Sherry, or Madeira, should be preferred. The medicated wines, in consequence of their liability to change, should be prepared in small quantities, without heat, and should be kept in well stopped bottles in a cool place. W.

VINUM ALOES. *U.S., Lond., Dub.* VINUM ALOES SOCOTORINÆ. *Ed.* *Wine of Aloes.*

"Take of Aloes, in powder, *an ounce;* Cardamom [seeds], bruised, Ginger, bruised, each, *a drachm;* Wine [Teneriffe] *a pint.* Macerate for fourteen days, with occasional agitation, and filter through paper. *U. S.*

The *Edinburgh* process differs from the above only in using two pounds of Sherry wine instead of a pint of Teneriffe, and digesting for one week instead of macerating for two.

"Take of Extract of the Aloe spicata *eight ounces;* Canella Bark *two ounces;* Proof Spirit, Distilled Water, each, *four pints.* Rub the Aloes into powder with clean white sand; rub the Canella Bark also into powder; and upon these, mixed together, pour the Spirit and Water. Macerate for fourteen days, occasionally stirring, and filter." *Lond.*

The *Dublin College* employs a menstruum consisting of three measures of Spanish white wine (Sherry), and one of proof spirit. In other respects its formula corresponds with that of the London College, one-half the quantity only being made, and the aloes being powdered without sand.

The sand directed by the London College assists in the pulverization of the aloes, and is said to prevent it from running together into masses when moistened by the fluid.

The wine of aloes is a warm stomachic purgative, useful in constipation dependent on a want of due irritability of the alimentary canal, and in complaints connected with this state of the bowels. It has long been used in chlorosis, amenorrhœa, dyspepsia, gout, paralysis, &c. It is said to leave behind it a more lax condition of the bowels than most other cathartics. The dose as as tomachic is one or two fluidrachms, as a purgative from half a fluidounce to two fluidounces. W.

VINUM COLCHICI RADICIS. *U.S.* VINUM COLCHICI. *Lond.* *Wine of Meadow-saffron Root.*

"Take of Meadow-saffron Root, bruised, *half a pound;* Wine *a pint.* Macerate for fourteen days, with occasional agitation, and filter through paper." *U.S.*

"Take of fresh Meadow-saffron Root, sliced, *a pound;* Proof Spirit *four fluidounces;* Distilled Water *eight fluidounces.* Macerate for fourteen days and filter." *Lond.*

This is intended to be a saturated vinous tincture of colchicum. The dried bulb is necessarily employed in this country, as the fresh is not kept in the shops. As the colchicum imported into the United States is of variable strength, the only method by which an active preparation can be ensured, is to employ a large quantity of the bulb in proportion to that of the menstruum. If the former should happen to be in excess, no other injury could result than a slight pecuniary loss, while a deficiency in the strength of the preparation would frequently be of serious detriment in urgent cases of disease. We have never been disappointed in obtaining the effects of colchicum from the wine which we knew to have been prepared according to the direction of the U. S. Pharmacopœia, while that which has been made with a smaller quantity of the bulb has often failed in our hands. The dose is from ten minims to a fluidrachm, to be repeated three or four times a day, or more frequently in severe cases, till its effects are experienced. In gout it is frequently given in connexion with magnesia; and in neuralgic cases we have found much advantage from combining it with the solution of sulphate of morphia, especially when we have desired to give it a direction rather to the skin than the bowels. W.

VINUM COLCHICI SEMINIS. *U.S.* *Wine of Meadow-saffron Seed.*

"Take of Meadow-saffron Seed, bruised, *an ounce;* Wine [Teneriffe] *a pint.* Macerate for fourteen days, with occasional agitation, and filter through paper." *U.S.*

As the seeds of colchicum are less liable to injury than the bulb, and are therefore of more uniform strength, there is not the same necessity for preparing a saturated tincture. The proportion of the seeds in the above process is the same as that recommended by Dr. A. T. Thomson in his Dispensatory. It would, perhaps, have been better, had two ounces been employed instead of one, so that the wine might have corresponded in strength with the officinal tinctures of the British Colleges in which the seeds are employed. (See *Tinctura Seminum Colchici*, Dub., and *Spiritus Colchici Ammoniatus*, Lond.) Dr. Williams, who introduced the seeds into use, recommends that they should not be bruised, as their virtues reside in their outer coat. The dose of this wine is one or two fluidrachms. W.

VINUM GENTIANÆ COMPOSITUM. *U.S., Ed.* *Compound Wine of Gentian.*

"Take of Gentian, bruised, *half an ounce;* Peruvian Bark, in powder, *an ounce;* Orange Peel, bruised, *two drachms;* Canella, bruised, *a drachm;* Diluted Alcohol *four fluidounces;* Wine [Teneriffe] *two pints.* Macerate for fourteen days, with occasional agitation, and filter through paper." *U.S.*

The *Edinburgh College* takes the quantities above mentioned of gentian, Peruvian Bark, Seville orange peel, and Canella; pours upon them, previously sliced and bruised, four ounces of diluted alcohol; then, after twenty-four hours, adds two pounds and a half of Sherry wine; and macerates for seven days.

This is a stomachic bitter, sometimes employed to promote appetite and invigorate digestion. It is apt, however, to become sour when kept. The dose is from four to eight fluidrachms. W.

VINUM IPECACUANHÆ. *U.S., Lond., Ed., Dub.* *Wine of Ipecacuanha.*

"Take of Ipecacuanha, bruised, *an ounce.* Wine [Teneriffe] *a pint.* Macerate for fourteen days, with occasional agitation, and filter through paper." *U.S.*

The *London College* takes two ounces of the bruised root, twelve fluidounces of proof spirit, and twenty fluidounces of distilled water; the *Dublin College*, two ounces of the bruised root, and two pints of Sherry Wine; both macerate for two weeks. The *Edinburgh College* employs one part of the root and fifteen parts of Sherry wine, and macerates for a week.

The preparations of the different Pharmacopœias are of the same strength. Wine of ipecacuanha possesses all the virtues of the root, and may be used as a substitute when it is desirable to administer the medicine in a liquid form. As it is milder, without being less efficacious than antimonial wine, it is in some instances preferable as an emetic in infantile cases, especially when the antimonial, as not unfrequently happens, is disposed to produce griping and irritation of the bowels. Under the same circumstances, it may be used as an expectorant and diaphoretic; and the effects of the Dover's powder may be obtained by combining it with laudanum or other liquid preparation of opium. The dose as an emetic, for an adult, is a fluidounce; as an expectorant and diaphoretic; from ten to thirty minims. A fluidrachm may be given as an emetic to a child one or two years old, and repeated every fifteen minutes till it operates. W.

VINUM OPII. *U.S., Lond., Ed., Dub.* *Wine of Opium.* *Sydenham's Laudanum.*

"Take of Opium *two ounces;* Cinnamon bruised, Cloves bruised, each, *a drachm;* Wine [Teneriffe] *a pint.* Macerate for fourteen days, with occasional agitation, and filter through paper." *U.S.*

The *London College* takes an ounce of extract of opium, a drachm of bruised cinnamon, a drachm of bruised cloves, six fluidounces of proof spirit, and ten fluidounces of distilled water; and macerates for eight days. The *Edinburgh College*, to the same quantity of extract of opium, cinnamon, and cloves, adds sixteen ounces of Sherry wine, and macerates for a week. The *Dublin College* takes an ounce of Turkey opium, a drachm of cinnamon, a drachm of cloves, and a pint of Sherry wine, and macerates for eight days.

The wine made according to the directions of the U. S. Pharmacopœia is a stronger preparation than that of the British Colleges, being a saturated vinous tincture of opium. It contains about the same proportions of the ingredients as the *laudanum of Sydenham*, from which it differs only in wanting a drachm of saffron. The spices which it contains are thought to adapt it to certain states of the stomach or system, in which the simple tincture of opium is found to produce unpleasant effects; but the same end may be obtained by an extemporaneous addition of some aromatic oil to the latter. Mr. Ware recommends it as a local application to the eye, in the latter stages of ophthalmia, when the vessels of the conjunctiva still remain turgid with blood. Two or three drops are introduced into the eye every morning till the redness disappears. The dose of the wine of opium is the same with that of the tincture. W.

VINUM RHEI. *U.S., Ed.* *Wine of Rhubarb.*

"Take of Rhubarb, bruised, *two ounces;* Canella, bruised, *a drachm;* Diluted Alcohol *two fluidounces* [two ounces, *Ed.*]; Wine *a pint* [Sherry Wine fifteen ounces, *Ed.*]. Macerate for fourteen days [seven days, *Ed.*], with occasional agitation, and filter through paper." *U.S., Ed.*

This is a warm cordial laxative, applicable to debilitated conditions of the system or alimentary canal requiring evacuation of the bowels. The dose is from two to eight fluidrachms or more, according to the amount of effect required, and the condition of the patient. W.

VINUM TABACI. *U.S.* VINUM NICOTIANÆ TABACI. *Ed.* *Wine of Tobacco.*

"Take of Tobacco, cut in pieces, *an ounce;* Wine [Teneriffe] *a pint.* Macerate for fourteen days, with occasional agitation, and filter through paper." *U.S.*

The *Edinburgh College* takes one part of dried tobacco leaves, and twelve parts of Sherry wine, and macerates for seven days.

The dose of the wine of tobacco as a diuretic, is from ten to thirty minims. It is very seldom used. W.

VINUM VERATRI ALBI. *U.S.* VINUM VERATRI. *Lond.* *Wine of White Hellebore.*

"Take of White Hellebore [root], bruised, *four ounces;* Wine [Teneriffe] *a pint.* Macerate for fourteen days with occasional agitation, and filter through paper." *U.S.*

The *London College* takes eight ounces of the sliced root, a pint of proof spirit, and a pint and a half of distilled water, and macerates for fourteen days.

It has been supposed that the wine of white hellebore, in consequence of the veratria which it contains, would act in the same manner with colchicum in the cure of gout and rheumatism; but it is uncertain and occasionally violent in its operation, and is very little used. The dose is ten minims two or three times a day, to be gradually increased till the peculiar effects of the medicine are experienced. W.

ZINCUM.

Preparations of Zinc.

ZINCI ACETAS. *U.S.* *Acetate of Zinc.*

"Take of Sulphate of Zinc *six ounces;* Acetate of Lead *eight ounces;* Distilled Water *a gallon.* Dissolve the Sulphate of Zinc and Acetate of Lead severally in four pints of the Distilled Water; then mix the solutions, and filter through paper; lastly, evaporate the filtered liquor, so that upon cooling it may crystallize." *U.S.*

Upon mingling the solutions of sulphate of zinc and acetate of lead, a double decomposition takes place, resulting in the formation of acetate of zinc which remains in solution, and sulphate of lead which precipitates. This latter is removed by filtration, and the clear liquor, by due evaporation, furnishes crystals of acetate of zinc. The proper quantities for mutual decomposition are 143.4 parts of the sulphate to 190.08 of the acetate, or one equiv. of each salt in the crystallized state. This ratio corresponds very nearly with that of the Pharmacopœia, which directs only a slight excess of the acetate.

A better method, according to Dr. Turner, for preparing this salt, is to suspend a piece of zinc in a dilute solution of acetate of lead for a sufficient length of time. The zinc takes the place of the lead, acetate of zinc is formed, and the lead is precipitated on the surface of the zinc in an arborescent form, called *arbor Saturni*, or *lead tree.* The precipitation of lead is known to be complete, when sulphuretted hydrogen produces in the solution a pure white precipitate. By this process the acetate of zinc is obtained quite pure.

Properties, &c. Acetate of zinc is in the form of white silky crystals, having the shape of hexagonal plates. It is very soluble in water, and slightly efflorescent in dry air. When heated before the blow-pipe on charcoal, it burns in the same manner with zinc. It is decomposed at a high temperature, and yields when distilled a considerable quantity of *pyro-acetic spirit.* It consists of one equiv. of acetic acid 51.48, one of oxide of zinc 40.3, and seven of water 63=154.78.

Medical Properties and Uses. Acetate of zinc is used as an external remedy only, for the most part as an astringent collyrium in ophthalmia, and injection in gonorrhœa, after the acute stage in these affections has passed over. It is officinal, in the crystallized state, only in the U.S. Pharmacopœia; the Edinburgh and Dublin Colleges ordering it, the former in aqueous solution, the latter in tincture. (See the *two following articles.*) It is, however, an improvement, to have the salt officinal in the solid form; as this state permits of its being prescribed in any desired proportion in solution, according to the nature of the case to which it is to be applied. The average strength of the solution, usually employed, is a grain of the salt to a fluidounce of distilled water. B.

SOLUTIO ACETATIS ZINCI. *Ed.* *Solution of Acetate of Zinc.*

"Take of Sulphate of Zinc *a drachm;* Acetate of Lead *four scruples;*

Distilled Water *twenty ounces* [by weight]. Dissolve the salts separately, each in ten ounces of the Water. Mix the solutions, and after the precipitate has subsided, filter the liquor." *Ed.*

In this formula, precisely the same changes take place as in the last; but the acetate of zinc, instead of being obtained in a solid state by evaporation, is allowed to remain in solution. The proportion also in which the salts are used is the same. From the amount of materials employed, it may be determined by calculation, that each fluidounce of the solution will contain about three grains of the acetate of zinc.

Medical Properties and Uses. The medical properties of this solution are the same with those of acetate of zinc. The salts employed to form it were formerly frequently prescribed together as an injection in gonorrhœa; but as a double decomposition necessarily took place, the prescription was equivalent to ordering a solution of acetate of zinc, mingled with a portion of the insoluble sulphate of lead. This mode of prescribing the acetate is objectionable, as the sulphate of lead is probably inert, if not injurious to the urethra. B.

ZINCI ACETATIS TINCTURA. *Dub.* *Tincture of Acetate of Zinc.*

"Take of Sulphate of Zinc, Acetate of Potassa, each, *one part.* Rub them together, and add of Rectified Spirit *sixteen parts.* Macerate for a week, with occasional agitation, and filter through paper." *Dub.*

In this process, the acetate of potassa first dissolves in the alcohol, and then reacts upon the sulphate of zinc; and in consequence of a double decomposition, sulphate of potassa and acetate of zinc are formed. Of these salts, the latter only is soluble in the rectified spirit, while the former remains undissolved, and is removed by the filtration.

Properties, &c. This tincture is transparent and colourless, and when evaporated nearly to dryness, affords crystals of acetate of zinc, recognizable by their shape and silky appearance. (See *Zinci Acetas.*) It is much stronger than the aqueous solution of the Edinburgh College, noticed in the preceding article; and, on account of the nature of its menstruum, is necessarily more stimulating. It is employed as an astringent collyrium and injection, but requires to be diluted with water. B.

ZINCI CARBONAS PRÆPARATUS. *U.S.* CALAMINA PRÆPARATA. *Lond.* CARBONAS ZINCI IMPURUS PRÆPARATUS. *Ed.* ZINCI CARBONAS IMPURUM PRÆPARATUM. *Dub.* *Prepared Carbonate of Zinc. Prepared Calamine.*

"Take of Carbonate of Zinc *any quantity.* Heat it to redness, and afterwards pulverize it; then reduce it to a very fine powder, in the manner directed for the preparation of Carbonate of Lime." *U.S.*

The *London* and *Dublin* processes agree essentially with the above.

"The Impure Carbonate of Zinc, after being roasted by those who make brass, is to be pulverised in an iron mortar, and levigated on a porphyry stone with a little water, and then put into a capacious vessel, and water poured upon it, which, after frequent agitation, is to be poured off while loaded with the powder. The subtle powder, which subsides on allowing the water to stand at rest, is to be dried. The coarse powder, which the water cannot suspend, is again to be levigated, and treated in the same manner." *Ed.*

The nature, properties, and composition of the native carbonate of zinc have been explained under another head. (See *Zinci Carbonas.*) The object of this process is to bring it to the state of an impalpable powder. It is first calcined, to render it more readily pulverizable, and then levigated and elutriated. During the calcination, water, and more or less carbonic acid are driven off; so that little else remains than the oxide of zinc, and the earthy impurities originally existing in the mineral.

Properties, &c. Prepared carbonate of zinc is in the form of a reddish-yellow powder, of an earthy appearance. It is used only as an external application, being employed as a mild astringent and exsiccant in excoriations and superficial ulcerations. For this purpose, it is dusted on the part, and hence the necessity for its being very finely levigated. It is often employed in the form of cerate. (See *Ceratum Zinci Carbonatis.*)

Off. Prep. Ceratum Zinci Carbonatis, *U.S.*, *Lond.*, *Ed.*, *Dub.* B.

ZINCI OXIDUM. *U.S.* ZINCI OXYDUM. *Lond.*, *Dub.* OXIDUM ZINCI. *Ed.* *Oxide of Zinc.*

"Take of Sulphate of Zinc *a pound;* Water of Ammonia *a sufficient quantity;* Distilled Water *four pints.* Dissolve the Sulphate of Zinc in the Distilled Water, and add sufficient Water of Ammonia to precipitate the whole of the Oxide of Zinc. Having poured off the clear liquor, wash the powder repeatedly with Distilled Water, and dry it by means of a sand-bath." *U.S.*

The *London College* takes a pound of the sulphate of zinc, a pint, or a sufficient quantity of water of ammonia, and a pint of distilled water, and proceeds as above.

"Place a large crucible in a furnace filled with live coals, so as to be somewhat inclined towards its mouth, and when the bottom of the crucible is moderately red, throw into it a piece of Zinc, *about a drachm* in weight. The Zinc soon inflames, and is converted at the same time into white flocks, which are to be removed from time to time from the surface of the metal by means of an iron spatula, in order that the combustion may be more complete; and at length, when the inflammation has ceased, the Oxide of Zinc is to be taken out of the crucible. Another piece of Zinc being then thrown in, the operation is to be gone through again, and may be repeated as often as necessary. Lastly, the Oxide of Zinc is to be prepared in the same manner as the impure Carbonate of Zinc." *Ed.*

"Take of Zinc, broken into pieces, *any quantity.* Throw it at intervals into a sufficiently deep crucible, heated to redness, and placed with its mouth inclined towards the mouth of the furnace. After the injection of each piece of Zinc, cover the crucible with another inverted over it, but loosely, so that the air may not be excluded. Preserve the light and very white sublimed powder for use." *Dub.*

The Pharmacopœias here adopt two different processes for obtaining this oxide, which require to be noticed separately. In the U.S. and London processes it is obtained by precipitation; in the Edinburgh and Dublin, by combustion. When ammonia is added to the solution of sulphate of zinc, sulphate of ammonia is formed, and oxide of zinc, in the state of hydrate, is thrown down as a gelatinous precipitate. Care must be taken not to add the ammonia in excess, as in that case it dissolves the precipitate at first produced. Pure sulphate of zinc should be employed, and not the sulphate of commerce, as the latter contains iron, which would be thrown down along with the oxide of zinc. If the commercial salt be used, the iron may be got rid of by adding an excess of ammonia, which will dissolve the pure oxide of zinc, to the exclusion of the oxide of iron. The ammoniacal solution, after being filtered, may then be evaporated to dryness, and the dry mass calcined. The *London College* has committed the error of ordering too little water for effecting the solution of the sulphate of zinc. This oversight has been corrected in the U.S. formula, in which, as recommended by Mr. Phillips, the water is taken at about five times the weight of the sulphate.

In the processes of the *Edinburgh* and *Dublin Colleges*, the combustibility of zinc is taken advantage of for producing this oxide. Zinc, when subjected to heat, melts at 680°, and immediately becomes covered with a film of gray oxide. When the temperature reaches nearly to redness, it takes fire and burns with an intense white light, giving rise to the oxide in the form of very light and white flocculi, resembling wool, which quickly fill the crucible, and are in part driven into the atmosphere by the current of air. It is to prevent loss from the latter circumstance, that the crucible, in the officinal formula, is inclined towards the mouth of the furnace, a position which prevents the axis of the crucible from coinciding with the direction of the draught. The oxide formed in the first instance, by covering the melted metal, impedes its further oxidation; and hence the necessity of continually removing it with a spatula or iron spoon, so as to expose a bright metallic surface to the action of the air. Notwithstanding every precaution, small portions of the metal will be mixed with the oxide when prepared in this way, and hence the *Edinburgh College* has ordered the product to be levigated and elutriated. The zinc is directed to be thrown into the crucible in successive pieces; but a better and more expeditious method is to put the whole of the zinc, intended to be converted into oxide, into a crucible large enough to be only two-thirds filled by it. Heat being applied, the zinc soon melts, and afterwards catches fire; and the oxide, as it is formed, is to be removed by means of a ladle with a long handle, until the whole of the metal is consumed.

Properties, &c. Oxide of zinc is in the form of an inodorous, tasteless, white powder, insoluble in water or alcohol. It is insoluble also in the carbonated fixed alkalies, but dissolves readily in acids, and, when newly precipitated and moist, in the caustic fixed alkalies, and in ammonia whether pure or carbonated. It is not decomposed nor volatilized by heat, and is very difficult of fusion. When heated moderately, it becomes yellow, and white again upon cooling if iron is not present; but otherwise, the yellow tint remains permanent. When prepared by combustion, it was formerly called *pompholix*, *nihil album*, *lana philosophica*, and *flowers of zinc*. It is sometimes adulterated with white lead or chalk. If it contain either, it will not be entirely soluble in dilute sulphuric acid, but an insoluble sulphate of lead or of lime will remain behind. When pure, its neutral solutions in acids give a white precipitate with sulphuretted hydrogen, or ferrocyanate of potassa. This oxide is the only well characterized compound of zinc with oxygen, and is uniformly present in the salts of this metal; but Berzelius and Thenard mention two others, a *suboxide* and a *superoxide*, which are not salifiable. It consists of one equiv. of zinc 32.3, and one of oxygen 8=40.3.

Medical Properties and Uses. Oxide of zinc has tonic properties, and has been used with advantage in chorea, epilepsy, hooping cough, spasms of the stomach dependent on dyspepsia, and other similar affections. Externally it is employed as an exsiccant to excoriated surfaces; sometimes by sprinkling it on the affected part, but generally in the form of ointment. (See *Unguentum Zinci Oxidi.*) The dose is from two to eight grains, several times a day, given in the form of pill. For internal use, the precipitated, as the purer oxide, should be preferred.

Off. Prep. Unguentum Zinci Oxidi, *U.S.*, *Lond.*, *Ed.*, *Dub.* B.

OXIDUM ZINCI IMPURUM PRÆPARATUM. *Ed. Prepared Impure Oxide of Zinc. Prepared Tutty.*

"This is prepared in the same manner as the Impure Carbonate of Zinc." *Ed.*

The nature of the impure oxide of zinc has been explained under another head. (See *Oxidum Zinci Impurum, Ed.*) The preparation which it is directed to undergo, consists in levigation and elutriation, with a view to bring it to the state of an impalpable powder. It is only used externally as an exsiccant to excoriations, being either dusted upon them tied up in a muslin bag, or applied in the state of an ointment. This oxide, however, is a useless addition to the materia medica; as, owing to its impurity and variable quality, it can in no case advantageously replace the pure oxide, which is officinal with all the Pharmacopœias. B.

Off. Prep. Unguentum Oxidi Zinci Impuri, *Ed.*

ZINCI SULPHAS. *U.S., Lond., Dub.* SULPHAS ZINCI. *Ed. Sulphate of Zinc. White Vitriol.*

"Take of Zinc, cut in small pieces, *four ounces;* Sulphuric Acid *six ounces;* Distilled Water *four pints.* To the Zinc and Water, previously introduced into a glass vessel, add by degrees the Sulphuric Acid; and when the effervescence shall have ceased, filter the solution through paper; then boil it down till a pellicle begins to form, and set it aside to crystallize." *U.S.*

The *London* process differs from the above, merely in directing the materials to be mixed, without specifying in what order.

"Take of zinc, cut into small pieces, *three parts;* Sulphuric Acid *five parts;* Water *twenty parts.* Mix them, and when the effervescence has ceased, digest for a little while on hot sand. Then pour off the solution, and filter it through paper; and after due evaporation, set it aside that crystals may form." *Ed.*

"Take of Zinc, broken into small pieces, *thirteen parts;* Sulphuric Acid *twenty parts;* Water *one hundred and twenty parts.* Put the Zinc into a glass vessel, and gradually add the Acid, previously diluted with the Water. When the effervescence has ceased, digest for a little while. Then filter and evaporate the solution, and after sufficient concentration, set it aside that crystals may form." *Dub.*

By this process, a pure and crystallized sulphate of zinc is obtained. *Strong* sulphuric acid has very little action on zinc, but when *diluted,* water is instantly decomposed, and while its hydrogen escapes with rapid effervescence, its oxygen combines with the zinc, and the oxide formed, uniting with the sulphuric acid, generates the sulphate of zinc. Thus it is perceived that *hydrogen* is a collateral product of this process, which, being easily performed, is generally resorted to for obtaining that gas. The proportions employed in the several formulæ are somewhat different. The zinc is to the acid as 4 to 6 in the U. S. and London processes; as 4 to 6.66 in the Edinburgh; and as 4 to 6.15 in the Dublin. The equivalent numbers give the ratio of 4 to 6.08; which indicates that the U. S. and London numbers approach very nearly to the true proportion. The U. S. Pharmacopœia is more precise than that of London or Edinburgh, as to the mixture of the materials. If they be mixed at once, without any precaution, the effervescence of hydrogen is apt to be excessive, and to cause the overflowing of the liquid. This is avoided by the Dublin direction to add the diluted acid gradually to the zinc, and more completely still in the U. S. formula, in which the solution of the zinc is commenced by a very dilute acid, which, as the action slackens, is made by degrees stronger and stronger, by the addition, at intervals, of small portions of fresh acid.

Preparation on a large scale. Sulphate of zinc in an impure state, as it occurs in commerce, is called *white vitriol.* In this state it is manufactured by roasting *blende* (native sulphuret of zinc) in a reverberatory furnace. This mineral, besides sulphuret of zinc, contains small quantities of the sulphurets of iron, lead, and copper; and by roasting is converted, in consequence of the oxidation of its constituents, into sulphate of zinc, mixed with the sulphates of iron, copper, and lead. The roasted matter is then lixiviated, and the solution obtained, after being allowed to settle, is concentrated by evaporation; so that, on cooling, it may concrete into a white crystalline mass, resembling white sugar. In this state, it always contains sulphate of iron, and sometimes a small portion of sulphate of copper. It may be purified to a certain extent by dissolving it in water, and boiling the solution with oxide of zinc, which converts the sulphates of iron and copper, by precipitating their bases, into sulphate of zinc. The purified solution is then decanted or filtered, and, after due evaporation, is allowed to crystallize. It has generally been proposed to purify the white vitriol of commerce by digesting its solution with metallic zinc, under an impression that this is capable of precipitating all the foreign metals; but, according to Berzelius, though it will precipitate copper readily, it has no action on the sulphate of iron. Neither is it capable of precipitating the base of sulphate of magnesia, a salt which is a very common impurity in white vitriol; and this objection is applicable also to the oxide of zinc as a precipitant.

Properties, &c. Sulphate of zinc is a white transparent salt, having a disagreeable, metallic, styptic taste, and crystallized usually in slender four-sided prisms, terminated by four-sided pyramids. Its crystals have considerable resemblance to those of sulphate of magnesia. It effloresces slightly in dry air, and though neutral in composition, is still capable of reddening vegetable blues. It dissolves in two and a half times its weight of cold, and in less than its weight of boiling water, and is insoluble in alcohol. When heated, it dissolves in its water of crystallization, which gradually evaporates; and by a prolonged ignition, the whole of the acid is expelled, and oxide of zinc is left. The caustic alkalies first precipitate its oxide, and then dissolve it when added in excess. The alkaline carbonates throw down the metal in the state of white carbonate. Pure sulphate of zinc is precipitated white by ferrocyanate of potassa. If copper be present, ammonia will produce a blue tinge; if iron, the ferrocyanate of potassa will cause a blue precipitate instead of a white one. Sulphate of zinc is incompatible with alkalies and alkaline carbonates, hydrosulphates, and lime-water, and causes a precipitate in astringent vegetable infusions.

The impure commercial variety of sulphate of zinc, called white vitriol, is in the form of irregular opaque masses, having some resemblance to white sugar. The lumps usually present, here and there, on the surface, yellow stains, produced by the oxide of iron. It is less soluble than the pure salt, on account of its containing less water of crystallization.

Composition. Crystallized sulphate of zinc consists of one equiv. of sulphuric acid 40.1, one of oxide of zinc 40.3, and seven of water 63=143.4. The white vitriol of commerce contains but three equivalents of water.

Medical Properties and Uses. This salt is tonic, astringent, and, in large doses, a prompt emetic. As a tonic, it is supposed to be well suited to cases of debility attended with irritation, being less heating than sulphate of iron. In dyspepsia it has been used with advantage in very minute doses, as for instance, a quarter of a grain, repeated several times a day; but if its good effects are not soon apparent, it should be laid aside. In obstinate intermittents, it is a valuable resource, and may be given alone, or conjoined with cinchona or sulphate of quinia. But it is in spasmodic diseases, such as epilepsy, chorea, pertussis, &c., that it has been principally employed as an internal remedy. Dr. Paris speaks of its efficacy in high terms, in spasmodic cough, especially when combined with camphor or myrrh, and "in affections of the chest attended with inordinate secretion." As an astringent, it is chiefly employed externally. In this mode of application, its solution constitutes a good styptic to bleeding surfaces, and is frequently resorted to as an injection in fluor albus and the advanced stages of gonorrhœa, and as a collyrium in ophthalmia. In some conditions of ulcerated sorethroat, it is found useful as a gargle. Before the discovery of tartar emetic, sulphate of zinc was almost exclusively employed to produce vomiting; but at present its use as an emetic is restricted principally to the dislodging of poisons, for which purpose its property of operating rapidly renders it particularly well suited. The dose, as a tonic, is from one to two grains; as an emetic, from ten to thirty grains. To children affected with hooping cough, it may be given in doses of from an eighth to a quarter of a grain two or three times a day. When used as a collyrium, injection, gargle, or wash for indolent ulcers, from one to three grains, or more, may be dissolved in a fluidounce of water. For medical purposes, the crystallized salt should be used, and in no case the impure white vitriol of commerce.

Off. Prep. Liquor Aluminis Compositus, *Lond.;* Solutio Acetatis Zinci, *Ed.;* Solutio Sulphatis Zinci, *Ed.;* Zinci Acetatis Tinctura, *Dub.;* Zinci Oxidum, *U.S.*, *Lond.* B.

SOLUTIO SULPHATIS ZINCI. *Ed.* *Solution of Sulphate of Zinc.*

"Take of Sulphate of Zinc *sixteen grains;* Water *eight ounces* [by weight]; Diluted Sulphuric Acid *sixteen drops.* Dissolve the Sulphate of Zinc in the Water; then, having added the Acid, filter through paper." *Ed.*

This formula is *intended* to furnish a solution of sulphate of zinc of proper strength for use as a collyrium and injection. The employment of the impure commercial salt appears to be contemplated by the *Edinburgh College;* and hence the diluted sulphuric acid is directed, with the intention of dissolving any excess of oxide which it may contain. The use, however, of the impure salt is improper; and were it otherwise, the proportion of salt employed, and the presence of the acid, render it too stimulating for the purposes for which it was designed. For these reasons the formula might very well be dispensed with. B.

APPENDIX.

I. DRUGS AND MEDICINES NOT OFFICINAL.*

In the progress of the medical art, numerous remedies have at different times risen into notice and employment, which, by the revolutions of opinion to which our science is incident, or by the discovery of more efficient substitutes, have so far fallen into disrepute as to have been discarded from general practice, and no longer to hold a place in the officinal catalogues. Of these, however, some are still occasionally employed by practitioners and referred to by writers, and many retain a popularity as domestic remedies, or among empyrics, which they have lost with the medical profession generally. The attention of physicians must, therefore, frequently be called to them in the course of practice; and it is highly desirable to possess some knowledge of their properties and effects, in order to be enabled to judge of their agency in any particular case, and at the same time to avoid the suspicion of incompetence which might attach to the exhibition of entire ignorance in relation to them. The remark is true also of other substances, which, though at no time ranked among regular medicines, are yet habitually employed in families, and the influence of which, either remediate or otherwise, must often enter into our estimate of the causes which produce or modify disease. New medicines, moreover, are frequently brought forward, which, without having obtained the sanction of the medical authorities, are occasionally prescribed, and therefore merit notice. To supply, to a certain extent, the requisite means of information in regard to these extra-officinal remedies, is the object of the following brief notices, among which are also included accounts of substances not employed as medicines, but usually kept in the drug stores for various purposes connected with the arts, or with domestic convenience. In a work intended for the use as well of the apothecary and druggist, as of the physician and medical student, the introduction of such accounts is obviously proper, if kept in due subordination to the more important object of teaching the properties of medicines, and the mode of preparing them. The authors regret that the limits which practical convenience appears to require in a Dispensatory, do not admit of a more complete enumeration of the various drugs and medicines of the kind above alluded to, or of ampler details in relation to those actually treated of, than will be found in the following pages. They have endeavoured, however, in the selection of objects, to choose those which are likely most frequently to engage the attention of the Medical and Pharmaceutical professions, and, in the extent of the descriptions, to consult as far as possible the relative importance of facts, of which they could not detail the whole. In relation to the nomenclature employed, it may be proper to observe, that all those vegetable remedies, which, not being generally kept in the shops, have no current commercial name, are described under the scientific title of the plant producing them; while other substances are designated by the names which ordinary usage has assigned them.

---

* By the term officinal medicines, here as well as elsewhere in this work, are meant such as are designated in the United States and British Pharmacopœias.

ACETIC ETHER. *Æther Aceticus.* This ether was discovered by Lauraguais, in 1759. It may be formed by several processes, the chief of which are the following:—1. Mix 100 parts of alcohol, (sp. gr. 0.83) with 63 parts of concentrated acetic acid, and 17 parts of strong sulphuric acid, and distil 125 parts into a receiver, kept cold with wet cloths. 2. Distil to dryness, a mixture of 3 parts of acetate of potassa, 3 of alcohol, and 2 of sulphuric acid, and mix the distilled product with one-fifth of sulphuric acid, and distil a second time an amount of ether equal to the alcohol employed. 3. Distil 2 parts of effloresced acetate of lead, with 1 part of alcohol, and a little more than 1 part of sulphuric acid. In the two latter processes, the acetic acid is set free by the action of the sulphuric acid on the acetate employed.

Acetic ether is colourless, and possesses a very grateful odour, and a peculiar, agreeable taste. Its sp. gr. is 0.866 and its boiling point 160°. It undergoes no change by being kept. By contact of flame, it burns readily, diffusing an acid odour. It dissolves in seven and a half parts of water, and unites in all proportions with alcohol. It consists of one equiv. of acetic acid 51.48, one of etherine 28.48, and one of water 9=88.96. It is classed by Thenard as an organic-oxacid ether.

Acetic ether is occasionally used in medicine as a stimulant and antispasmodic. The dose is from fifteen to thirty drops, sufficiently diluted with water. It is sometimes employed externally, in frictions, as a resolvent, and for rheumatic pains.

ACHILLEA MILLEFOLIUM. *Milfoil. Yarrow.* This is a perennial herb, common to the old and new continents, though supposed to have been introduced into this country from Europe. It is abundant in old fields, along fences, and on the borders of woods and of cultivated grounds, throughout the United States. It is from a foot to eighteen inches high, and is distinguished by its doubly pinnate minutely divided leaves, from which it derived the name of milfoil, and by its dense corymb of whitish flowers, which appear throughout the summer, from June to September. The whole herb is medicinal. Both the flowers and leaves have an agreeable, though feeble aromatic odour, which continues after drying, and a bitterish, astringent, pungent taste. The aromatic properties are strongest in the flowers, the astringency in the leaves. The plant owes its virtues to a volatile oil, a bitter extractive, and tannin. The oil, which may be obtained separate by distillation with water, has the peculiar flavour of milfoil in a high degree. The active principles are extracted both by water and alcohol. The medical properties of the herb are those of a mild aromatic tonic and astringent. In former times it was much used as a vulnerary, and was also given internally for the suppression of hemorrhages, and of profuse mucous discharges. It has been recommended in intermittents, and as an antispasmodic in flatulent colic, and various affections dependent on nervous debility. At present it is little used. In some parts of Sweden it is said to be employed as a substitute for hops in the preparation of beer, which it is thought to render more intoxicating. It is most conveniently administered in the form of infusion. The volatile oil has been given in the dose of twenty or thirty drops.

ACTÆA SPICATA. *Baneberry. Herb Christopher.* This is a perennial, herbaceous, European plant, growing in the woods of mountainous regions, and attaining a height of two feet or more. The root is of a dark brown colour, and bears some resemblance to that of the Helleborus niger, for which it is said to be occasionally substituted in some parts of continental Europe. Its odour, in the recent state, is sweetish and rather nauseous, but is in great measure dissipated by drying. The taste is bitterish and somewhat acrid. In its operation on the system, the root is purgative and sometimes emetic, and is capable, in over doses, of producing dangerous effects. It is unknown in this country. We have, however, a native species of Actæa—the *A. Americana* of Pursh—of which there are two varieties—the *alba* and *rubra*—distinguished by the colour of their berries, which in the former are white, and in the latter red. They are sometimes called *white* and *red cohosh*, a name derived from the language of the aborigines. By some botanists they are considered as distinct species, under the name of *Actæa alba*, and *Actæa rubra*. They grow in the rich deep mould of shady and rocky woods, from Canada to Virginia. They are said to have been much esteemed by the Indians. Their medical properties are probably similar to those of the *A. spicata*. The name *baneberry*, applied to different species of Actæa, was derived from the reputed poisonous properties of their berries.

ADIANTUM PEDATUM. *Maidenhair.* An indigenous fern, the leaves of which are bitterish and somewhat aromatic, and have been supposed to be useful in chronic catarrhs and other pectoral affections. A European species known by the same vulgar name, is the *A. Capillus Veneris*, which has similar properties with the former, though feebler, and has been much used as a pectoral on the continent of Europe, from very early times. It is given in the form of infusion, sweetened with sugar or honey; and a syrup prepared from it is popular in France, under the name of *sirop de capillaire*. The name of maidenhair has also been given to the *Asplenium Trichomanes*, the leaves of which have a mucilaginous, sweetish, somewhat astringent taste, and have been used for the same purposes with those of the plants above mentioned. Another species of Asplenium, the *A. Adiantum-nigrum*, has been substituted for the genuine maidenhair; but neither of them has the aromatic flavour of that fern.

ÆSCULUS HIPPOCASTANUM. *Horsechesnut.* The horsechesnut is a native of Asia, and was introduced about the middle of the sixteenth century into Europe, where, as well as in this country, it is now extensively cultivated as an ornamental tree. The fruit and bark have been used in medicine. The *fruit* abounds in starch, but has a rough, unpleasant, bitter taste, which renders it unfit for food, though it is said to be eaten with avidity by horses, oxen, hogs, and sheep. It may be deprived, in great measure, of the bitter principle by maceration in an alkaline solution. It is asserted that the starch may be readily obtained in a state of purity, and that it excels as an article of diet that procured from the potato. (*Dict. de Mat. Med.*) The powdered kernel of the fruit, snuffed up the nostrils, produces sneezing, and has been used with advantage as a sternutatory in complaints of the head and eyes. The *bark* of the horsechesnut has attracted much attention on the continent of Europe, as a substitute for cinchona. That of the branches from three to five years old is considered best. It should be collected in the spring. The bark has little odour, but an astringent and bitter, though not very disagreeable taste. It contains, among other ingredients, bitter extractive and tannin, and imparts its virtues to boiling water. By numerous physicians it has been found very efficacious in the treatment of intermittent fever; but has entirely failed in the hands of many others; and certainly cannot be considered comparable to the Peruvian bark in its power over this complaint. It is at present very seldom used, and never in this country. It has been given in substance, decoction, and extract. From half an ounce to an ounce of the powder may be given in the course of twenty-four hours. The decoction is prepared and administered in the same manner with that of Peruvian bark.

AGAVE AMERICANA. *American agave. American aloe.* An evergreen succulent plant, indigenous in Florida, Mexico, and other parts of tropical America. This and other species of Agave bear a considerable resemblance, in appearance, to the plants of the genus Aloe, with which they are sometimes confounded. From the root and leaves of the American agave, when cut, a saccharine juice flows out, which may be converted by evaporation into syrup and even sugar, and by fermentation into a vinous liquor. This juice, when fresh, is said to be laxative, diuretic, and emmenagogue. The expressed juice, evaporated to the consistence of a soft extract, has the property of forming a lather with water, and is employed in some places as a substitute for soap. The fibres of the old leaves, separated by bruising and maceration in water, are used for forming thread.

AGRIMONIA EUPATORIA. *Common agrimony.* This species of agrimony is a perennial herb, inhabiting Asia, Europe, and North America, and in this country, found in fields and on the borders of woods, and flowering during the summer months. Its stem, which rises from one to three feet in height, is hairy, furnished with interruptedly pinnate leaves, and terminated by a long simple spike of yellow flowers. Both the herb and root have been employed. The former has a weak but agreeable aromatic odour, and a rough, bitterish, somewhat aromatic taste. The fragrance is strongest in the flowers. The root has similar properties; but its taste is more bitter and astringent. A volatile oil may be obtained from the plant by distillation with water. Agrimony is a mild corroborant and astringent. The herb has been considerably employed in relaxed conditions of disease, as in passive hemorrhages, and chronic affections of the mucous membranes. It has been highly recommended also, as a deobstruent in jaundice and visceral obstructions, and as an alterative in diseases of the skin. In Europe it is said to be popularly used, in the form of gargle, in affections of the throat. The Indians of North America and the Canadians are reported to have employed the root with advantage in fevers. The plant may be given in substance, infusion, or decoction. The dose of the powder is a drachm or more.

AJUGA CHAMÆPITYS. *Ground pine. Chamæpitys.* A low creeping, annual, labiate plant, a native of Europe, and found also in some parts of the United States.—The leaves, which bear some resemblance to those of the pine in shape, have a strong, peculiar, resinous, not disagreeable odour, and a bitter, balsamic taste. They yield by distillation with water a small proportion of volatile oil, resembling that of turpentine. They are said to be stimulant, diuretic, and aperient; and have been given in rheumatism, gout, palsy, and amenorrhœa. The dose of the leaves in powder is one or two drachms; but their infusion in wine is considered the best preparation.

The *Ajuga reptans* or *common bugle*, and the *A. pyramidalis*, perennial plants of Europe, have also been used in medicine. They are nearly inodorous, but have a somewhat astringent, bitterish, and saline taste. Their virtues are probably those of a mild astringent and tonic. They have been recommended in pulmonary consumption, hæmoptysis and other hemorrhages, and in hepatic obstructions, and have enjoyed considerable reputation as vulneraries; but they are at present nearly obsolete.

ALCHEMILLA VULGARIS. *Ladies-mantle.* A perennial European herb, growing in meadows, on the banks of rivulets, and in the borders of woods. The whole plant has an astringent bitterish taste, which is strongest in the root. It was formerly employed in diarrhœa, and other complaints requiring the use of astringents. By the ancients it was highly esteemed; and extraordinary powers were ascribed to it by the alchemists, from whom, according to Linnæus, it derived its generic title.

ALCORNOQUE. Under this name, a bark was introduced into Europe from South America, about thirty years since, and for a short time attracted considerable attention. It has been conjecturally referred by different writers to different plants; but its precise origin is unknown. In the Dictionary of Materia Medica of Merat and De Lens, it is described as being in large thick pieces, composed of two layers, of which the external is reddish, cracked, granular, spongy, and two or three lines in thickness, the internal lamellated, woody, and possessed of the property of imparting a yellow colour to the saliva when chewed. It is inodorous. The outer layer is of an astringent, somewhat bitter taste, and was thought to have febrifuge powers; the inner is much more bitter, and is decidedly emetic. The bark was brought into notice chiefly as a remedy in phthisis; but, failing to produce any favourable impression upon that complaint, in the hands of European practitioners, it has fallen into entire neglect. It was given in the form of powder, in the dose of thirty grains; or half an ounce of it was boiled in a pint of water down to half a pint, and two or three tablespoonfuls of the decoction were administered every two hours. In these doses it acted as an emetic.

ALISMA PLANTAGO. *Water plantain.* A perennial herbaceous plant, common to Europe and the United States, and growing in streams, pools, ditches, and other standing waters. The *root* has when fresh an odour like that of Florentine orris, but loses it when dried. Its taste is acrid and nauseous. It acquired at one time considerable credit as a preventive of hydrophobia, for which purpose it was said to have been used with great advantage in Russia; but subsequent experiments have proved its total inefficacy. The Calmucks are said to use it for food. The *leaves* are rubefacient, and will sometimes even blister when applied to the skin. They have been recommended in gravel and complaints of the bladder, in the dose of a drachm.

ALLIARIA OFFICINALIS, Andrz. *Erysimum Alliaria*, Linn. *Hedge garlic.* A perennial European herb, having when rubbed an odour like that of garlic, and of a bitterish somewhat acrid taste. When eaten it communicates an alliaceous smell to the breath. The herb and seeds are esteemed diuretic, diaphoretic, and expectorant, and have been given in humoral asthma, chronic catarrh, and other complaints in which garlic is considered useful. The herb has also been recommended as an external application in gangrenous affections, and to promote suppuration.

ALNUS GLUTINOSA. *Common European alder.* A European tree, of twenty-five feet or more in height, growing in swamps, on the sides of streams, and in other damp places. The bark and leaves are very astringent and somewhat bitter. The former has been used in intermittent fever, the latter as a topical remedy in wounds and ulcers. The bruised leaves are sometimes applied to the breast for the purpose of repelling the milk. The cones also are said to be astringent, and to form a useful gargle in complaints of the throat. All these parts of the tree are used in dying, and the leaves and bark in tanning. The *Alnus serrulata* or common *American alder* has propertiesanalogous to those of the European species.

AMBERGRIS. *Ambra grisea.* This substance, which is found floating on the sea, or thrown by the waves upon the shores of various countries, particularly in the southern hemisphere, is now generally believed to be produced in the intestines of the *Physeter macrocephalus* or spermaceti whale, and perhaps in those of some other fish. It is in roundish or amorphous pieces, usually small, but sometimes of considerable magnitude; and masses have been found weighing 50, 100, or even 200 pounds. These pieces are often composed of concentric layers. They are of various colours, usually gray, with brownish, yellow, and white streaks, often dark brown or blackish on the external surface. They are opaque, lighter than water, and of a consistence like that of wax. Ambergris has a peculiar aromatic agreeable odour, is almost tasteless, softens with the warmth of the hand, melts under 212°, is almost completely volatilizable by heat, and takes fire when heated in the open air. It is insoluble in water, but is readily dissolved, with the aid of heat, by alcohol, ether, and the volatile and fixed oils. It consists chiefly of a peculiar fatty matter analogous to cholesterin, and denominated by Pelletier and Caventou *ambrein.* This may be obtained by treating ambergris with heated alcohol, filtering the solution, and allowing it to stand. Crystals of ambrein are deposited. It differs from most other fatty matters by not forming soaps with the alkalies. When pure it has little or no odour. The other constituents of ambergris do not appear to have been thoroughly investigated. It is often adulterated; but does not then exhibit its ordinary fusibility and volatility. Ambergris was long regarded as a cordial and antispasmodic, somewhat analogous to musk in its mode of action; and has been recommended in typhoid fevers, and various nervous diseases. It formerly entered into a great variety of officinal preparations, and is still retained by some of the Pharmacopœias of the continent of Europe. It is, however, in all probability very feeble in remediate power, and is much more used in perfumery than in medicine. The dose is from five grains to a drachm.

ANACARDIUM OCCIDENTALE, Linn. *Cassuvium pomiferum*, Lam. *Cashew-nut.* A small and elegant tree, growing in the West Indies, and other parts of tropical America. A gum exudes spontaneously from the bark, which bears some resemblance in appearance to Gum Arabic, but is only in part soluble in water, and consists of proper gum and bassorin. It is the *gomme d'acajou* of the French writers. The fruit is more important. It is a fleshy, pear-shaped receptacle, supporting at its summit a hard, shining, ash-coloured, kidney-shaped nut, an inch or more in length, three-quarters of an inch broad, consisting of two shells, with a black juice between them, and of a sweet oily kernel within the inner shell. The receptacle is of a red or yellow colour, and of an agreeable sub-acid flavour with some astringency. It is edible, and affords a juice which has been recommended as a remedy in dropsy. This juice is converted by fermentation into a vinous liquor, from which a spirit is obtained by distillation, much used in making punch, and said to be powerfully diuretic. The nuts are well known under the name of *cashew nuts.* The black juice contained between their outer and inner shell, is extremely acrid and corrosive, producing, when applied to the skin, severe inflammation, followed by blisters or desquamation of the cuticle. It is used in the West Indies for the cure of corns, warts, ringworms, and obstinate ulcers, and is said to be sometimes applied to the face by females in order to remove the skin, and produce a fresher and more youthful aspect. The worst case of external poisoning which has ever come under our notice, was produced in a lady who was exposed to the fumes of the nut while roasting. The face was so much swollen that for some time not a feature was discernible. The kernel, when fresh, has a sweet, agreeable taste, and is eaten like chestnuts, either raw or roasted. It is also used as an ingredient of puddings, &c., and forms an excellent chocolate when ground with cocoa. By age it becomes rancid and loses its pleasant flavour. The black juice of the nut, and a milky juice which flows from the tree by incision, are sometimes used for marking linen, upon which they leave a nearly indelible brown or black stain.

ANAGALLIS ARVENSIS. *Scarlet pimpernel.* An annual plant, growing in Europe and this country, with small, delicate, procumbent stems, furnished with opposite branches, opposite ovate leaves, and small scarlet flowers, which are supported upon axillary, solitary peduncles, and appear in June and July. It is inodorous, and has a bitterish somewhat acrid taste. The ancients esteemed it as a counter-poison, and in modern times it has been used as a preventive of hydrophobia; but at present no faith is placed in its alexipharmic powers. It is, nevertheless, not wholly inactive; as Orfila found three drachms of an extract prepared from it sufficient to destroy a dog, with marks of inflammation of the bowels. It has been recommended as a local application in old and ill-conditioned ulcers, and has been given internally in visceral obstructions, consumption, dropsy, epilepsy, mania, &c. But too little is known of its precise properties, to authorize its indiscriminate employment in these complaints. Another species, considered by Linnæus as a mere variety of the A. arvensis, is the *A cærulea*, distinguished by its blue flowers. It is incorrectly designated by the older writers as the *female* plant, the former being called *male.* The medical properties of the two, so far as is known, are the same.

ANCHUSA OFFICINALIS. *Bugloss.* This species of Anchusa is a native of Europe, and unknown in the United States. It is a biennial plant, from one to three feet high, and was formerly much esteemed as a medicine. The root, leaves, and flowers, were all officinal. These are inodorous, and nearly tasteless. The root is mucilaginous and slightly sweetish, and the flowers very feebly bitter. The plant has no claim whatever to the credit, formerly attached to it, of possessing cordial and exhilarating properties. It was used by the ancients in hypochondriacal affections; but as it was given in wine, the elevation of spirits experienced may with propriety be ascribed to the vehicle. In France, the *Anchusa Italica*, which is there known as *buglosse*, is employed for the same purposes and in the same manner as the Borago officinalis.

ANDROMEDA ARBOREA. *Sorrel tree* A beautiful indigenous tree, growing in the valleys of the Alleghany mountains, from Pennsylvania to Florida. The leaves have a very pleasant acid taste, which has given rise to the common name of the tree. They are frequently used by hunters to allay thirst, and in decoction they form a grateful refrigerant drink in fevers.

The other species of Andromeda are shrubs, and some of them are ornamental. Dr. Barton, in his "Collections," states that a decoction of the *A. Mariana* is usefully employed, in the Southern States, as a wash in a disagreeable ulceration of the feet to which the Negroes are liable. The powder upon the leaves and buds of the *A. speciosa* is said to be a powerful errhine.

ANEMONE PRATENSIS. *Meadow anemone.* This plant enjoyed at one time considerable credit from the recommendation of Störck, who believed that he had found it useful in amaurosis and other complaints of the eye, in secondary syphilis, and in cutaneous eruptions. The *A. Pulsatilla*, an analogous species, has been employed for similar purposes; and favourable reports have been made of its efficacy in obstinate diseases of the skin, and in hooping-cough. The preparation employed was an extract of the herbaceous part of the plant, which was given by Störck in the dose of one or two grains daily, gradually increased to twenty grains or more. In large doses it was found frequently to produce nausea and vomiting, or griping and looseness of the bowels, and sometimes acted as a diuretic. The species of Anemone above mentioned are European plants, and are not cultivated in this country. We have several native species, which, however, are not employed. One of them, the *A. nemorosa*, which is common to Europe and the United States, is said to act as a poison to cattle, producing bloody urine and convulsions. It is stated also to have proved, when applied to the head, a speedy cure for tinea capitis. Most of the species are, in the recent state, acrid and rubefacient, resembling in this respect other Ranunculaceæ, to which family they belong.

ANIME. *Gum anime.* The substance known at present by the name of *anime*, is a resin supposed to be derived from the *Hymenæa Courbaril*, a tree of South America; though this origin is denied by Hayne, and is at least doubtful. It is in small, irregular pieces, of a pale lemon-yellow colour sometimes inclining to reddish, more or less transparent, covered with a whitish powder, brittle and pulverizable, with a shining fracture, a weak but agreeable odour, and a mild resinous taste. It softens in the mouth, adheres to the fingers when in the state of powder, and readily melts with heat, diffusing its agreeable odour in an increased degree. It consists of two distinct resins, one soluble, the other insoluble in cold alcohol, and of a small proportion of volatile oil. There is a variety of a darker colour, less transparent, and exhibiting small cavities in the interior; in other respects resembling the preceding. Another variety of anime is the East Indian, supposed to be derived from the *Vateria Indica;* but this never reaches us as a distinct article of commerce. Anime formerly entered into the composition of various ointments and plasters; but is now used only as incense, or in the preparation of varnishes. The Brazilians are said to employ it internally in diseases of the lungs.

ANNOTTA. *Orleana.* The colouring substance called *annotta*, *arnotta*, or *roucou*, is the reddish pulp surrounding the seeds in the fruit of the *Bixa Orellana*, a middling sized tree growing in Guiana, and other parts of South America. The pulp is separated by bruising the fruit, mixing it with water, then straining through a sieve, and allowing the liquid to stand till the undissolved portion subsides. The water is then poured off, and the mass which remains, having been sufficiently dried, is formed into flat cakes or cylindrical rolls, and sent into the market. Annotta is of a brownish-red colour, usually rather soft, but hard and brittle when dry, of a dull fracture, of a sweetish peculiar odour, and a rough, saline, bitterish taste. It is inflammable, but does not melt with heat. It softens in water, to which it imparts a yellow colour, but does not dissolve. Alcohol, ether, the oils, and alkaline solutions dissolve the greater part of it. The chief uses to which it is applied, are for dying silk and cotton orange-yellow, and for colouring cheese. The colour, however, which it imparts to cloth is fugitive. It has been given internally as a medicine; but is not now used, and probably exercises little influence upon the system. In pharmacy it is occasionally used to colour plasters, and has sometimes been substituted for saffron.

ANTIRRHINUM LINARIA. Linn. LINARIA VULGARIS, Lindley. *Common toadflax.* This species of Antirrhinum is a perennial herbaceous plant, from one to two feet high, with numerous narrow linear leaves, and a terminal crowded spike of large yellow flowers. It is a native of Europe, but has been introduced into this country, where it is now naturalized, and grows in great abundance along the road sides, throughout the Middle States. It is readily distinguishable by the shape of its leaf, and by its conspicuous yellow flowers, which appear in succession from June to October. The herb is the part used. It should be collected when in flower, dried quickly, and kept excluded from the air. When fresh it has a peculiar, heavy, rather disagreeable odour, which is in a great measure dissipated by drying. The taste is herbaceous, weakly saline, bitter, and slightly acrid. This plant is said to be diuretic and cathartic, and has been used in dropsy, jaundice, and various cutaneous eruptions. It is most conveniently employed in the state of infusion. The fresh plant is sometimes applied externally, in the shape of poultice or fomentation, to hemorrhoidal tumours; and an ointment made from the flowers has been used for the same purpose, and also as a local application in diseases of the skin.

AQUILEGIA VULGARIS. *Columbine.* A perennial herbaceous plant, indigenous in Europe, but cultivated in our gardens as an ornamental flower. All parts of it have been medicinally employed. The roots, leaves, and flowers have a disagreeable odour, and a bitterish, acrid taste. The seeds are small, black, shining, inodorous, and of an oleaginous sweetish taste, followed by a sense of acrimony. Columbine has been considered diuretic, diaphoretic, and antiscorbutic, and has been employed in jaundice, in small-pox to promote the eruption, in scurvy, and externally as a vulnerary. It is not used at present, and is even suspected to possess dangerous properties, like most other plants of the natural order of Ranunculaceæ to which it belongs.

ARECA NUT. *Betel nut.* This is the product of the Areca Catechu, an East India tree belonging to the family of palms. The fruit, which is about the size and shape of a small egg, and of an orange-yellow colour, contains the nut embedded in a fibrous fleshy envelope, and invested with a brittle shell which adheres to the exterior flesh. The kernel, which is the betel-nut of commerce, is of a roundish-conical shape, rather larger than a chestnut, externally of a deep brown, diversified with a fawn colour, so as to present a reticular appearance, internally brownish-red with whitish veins, very hard, of a feeble odour when broken, and of an astringent, somewhat acrid taste. It abounds in tannin, and contains also gallic acid, a fixed oil, gum, a little volatile oil, lignin, and various saline substances. It yields its astringency to water, and in some parts of Hindostan an extract is prepared from it having the appearance and properties of catechu. Immense quantities are consumed in the East, mixed with the leaves of the Piper Betel, and with lime, forming the masticatory so well known by the name of *betel.* The red colour which this mixture imparts to the saliva and the excrements, is owing to the Areca nut, which is also powerfully astringent, and by its internal use, tends to counteract the relaxation of bowels to which the heat of the climate so strongly predisposes. The nut is used in this country almost exclusively in the preparation of tooth-powder, for which purpose it is first reduced by heat to the state of charcoal. The superiority of this form of charcoal over that from other sources, is probably owing to the extreme hardness of its particles.

ASPARAGUS OFFICINALIS. *Asparagus.* This well known plant, so abundantly cultivated as a garden vegetable, is a native of Europe. It is perennial and herbaceous. The *root*, which is inodorous, and of a weak sweetish taste, was formerly used as a diuretic, aperient, and purifier of the blood; and is stated to be still employed to a considerable extent in France. It is given in the form of decoction, made in the proportion of one or two ounces of the root to a quart of water. Hayne asserts, that in the dried state it is wholly inert. The *young shoots*, as every one knows, are much used in spring as an article of diet. Before being boiled they have a disagreeable taste; and their juice was found by Robiquet and Vauquelin to contain a peculiar crystallizable principle, called *asparagin* (see p. 68.), which, however, is not known to exert any special influence on the system. The sprouts themselves are not without effect, as the urine acquires a disagreeable odour very soon after they have been eaten. They are considered by some writers as diuretic, aperient, and deobstruent, and as constituting a very wholesome and useful article of diet, early in the spring, when so few vegetables are to be obtained. Broussais thinks that they exert a sedative influence over the heart, and recommends them especially in hypertrophy and other diseases of that organ attended with excessive action, and without phlogosis of the stomach. M. Gendrin, however, after much experience with asparagus, affirms that he has never found it to exercise the slightest influence over the actions of the heart, and ascribes its palliative effects in diseases of that organ, to its diuretic action. From the experiments of M. Gendrin, it appears, that this medicine operates powerfully on the kidneys. He found it, in all the cases in which he administered it, to increase the quantity of urine, which in some instances was quintupled. The most convenient forms for exhibition are those of syrup and extract, prepared from the shoots. The former may be given in the dose of one or two fluidounces, the latter of half a drachm or a drachm. The syrup may be made by adding a sufficient quantity of sugar to the expressed juice of the shoots, previously deprived of its albumen by exposure to heat and by filtration; the extract, by evaporating the same juice to the consistence of a pilular mass. The *berries* are capable of undergoing the vinous fermentation, and affording alcohol by distillation. In their unripe state they possess the same properties with the shoots, and probably in a much higher degree. We have employed a syrup prepared from them, with apparent advantage, in a case of diseased heart.

ASPLENIUM FILIX FŒMINA, R. Brown. *Female fern.* This is the *Polypodium Filix fœmina* of Linn., the *Aspidium Filix fœmina* of Swartz, and the *Athyrium Filix fœmina* of Roth. It has a root analogous in character to that of the male fern (*Aspidium Filix mas*), and supposed to possess similar vermifuge properties. At present, however, it is not used. The vulgar name of *female fern* has also been bestowed upon the *Pteris aquilina*, or *common brake*, which is asserted by some authors to have the property of destroying the tape-worm. The leaves of two species of Asplenium, the *A. Trichomanes* or *common spleenwort*, and *A. Adiantum-nigrum*, or *black spleenwort*, are somewhat mucilaginous, and have been used as substitutes for the *Maidenhairs* (*Adiantum Capillus Veneris* and *A. pedata*) as pectorals, though destitute of the aromatic flavour, which is, perhaps, the chief recommendation of these plants.

BAPTISIA TINCTORIA. *Sophora tinctoria*, Linn. *Podalyria tinctoria*, Michaux. *Wild indigo.* This is an indigenous perennial plant, found in all parts of the United States, growing abundantly in woods and dry barren uplands. It is from one to three feet high, with a smooth, very branching stem, small, ternate, cuneate-obovate, bluish-green leaves, and yellow flowers, which appear in July and August, and, like the whole plant, become black when dried. The root, which is the part most highly recommended, is of a dark-brown colour, inodorous, and of a nauseous, somewhat acrid taste. Its virtues appear to reside chiefly in the cortical portion. In large quantities, it is said to operate violently as an emetic and cathartic; but in smaller doses, it produces only a mild laxative effect. Its general influence upon the system has not been accurately investigated. It is said to have proved useful in scarlatina, typhus fever, and in that state of system which attends gangrene or mortification. Dr. Thatcher speaks highly of its efficacy as an external application to obstinate and painful ulcers; and Dr. Comstock, of Rhode Island, found it extremely useful, both as an internal and external remedy, in threatened or existing mortification. By the latter physician it was given in decoction, made in the proportion of an ounce of the root to a pint of water, of which half an ounce was administered every four or eight hours, any tendency to operate on the bowels being checked with laudanum. It may be used externally in the form of decoction or of cataplasm. The stem and leaves are said to possess the same virtues with the root, though in a less degree. A pale blue colouring substance has been prepared from the plant as a substitute for indigo, but is greatly inferior.

BASSORA GUM. We are wholly ignorant of the plant which yields this substance. It came into commerce originally from the neighbourhood of Bassora, on the Gulf of Persia, but is frequently found mixed with gums brought from other countries, and is probably not the product of one plant exclusively. It is in irregular pieces, of various sizes, never very large, white or yellow, intermediate in the degree of its transparency between gum Arabic and tragacanth, inodorous, tasteless, and possessed of the property of yielding a slight sound when broken under the teeth. But a small portion of it is soluble in water, whether hot or cold. The remainder swells up considerably, though less than tragacanth, and does not, like that substance, form a gelatinous mass, as it consists of independent granules which have little cohesion. The soluble portion is pure gum, or as it is now sometimes named *arabin;* and, according to M. Guérin, constitutes 11.2 per cent. The insoluble portion consists of a peculiar principle called *bassorin*, associated with a small proportion of various saline substances, which yield, when the gum is burnt, 5.6 per cent. of ashes. The gum is useless both in medicine and pharmacy, and is described here only as an object to be avoided, and as affording a principle which enters into the composition of several officinal substances, and the nature of which, therefore, should be known.

Bassorin is insoluble in water, alcohol, and ether, but softens and swells up in hot or cold water. Diluted nitric and muriatic acids, with the aid of heat, dissolve it almost entirely. The acidulous solution, concentrated by evaporation and treated with alcohol, lets fall a flocculent precipitate which has all the characters of pure gum, into which the bassorin appears to have been converted by the action of the acid. This does not, however, constitute more than a tenth part of the bassorin dissolved. By gradually evaporating the alcoholic acidulous solution, a thick bitterish liquid is obtained, which exhales a strong odour of ammonia when treated with potassa. Strong nitric acid converts bassorin into mucic and oxalic acids; and, treated with sulphuric acid, it yields a sweet crystalline substance which is incapable of the vinous fermentation. (Guérin.) Vauquelin was the first to call attention to this principle, upon which he conferred its present name, from having first observed it in the Bassora gum. Bucholz afterwards discovered the same or a closely analogous principle in tragacanth; and John, a principle which was supposed to be the same, in the gum of the cherry tree; hence it has sometimes been called *tragacanthin* and *cerasin*. M. Guérin, however, has demonstrated that the insoluble principle of the cherry gum is essentially different from bassorin. Berzelius considers the latter as belonging to the class of substances which he associates together under the name of mucilage, and of which examples are furnished in the mucilages of flaxseed and of quince seed. For his views on this subject the reader is referred to the article Linum, in the Materia Medica.

BDELLIUM. A gum-resin brought from Arabia, or the neighbouring countries of the East, and said to be the product of the *Heudelotia Africana*. (*Journ. de Pharm.* xix. 250 and 312.) It sometimes comes mixed with gum Arabic and gum Senegal. It is either in small roundish pieces, of a reddish colour, semi-transparent, and brittle with a wax-like fracture, or in larger irregular lumps, of a dark brownish-red colour, less transparent, somewhat tenacious, and adhering to the teeth when chewed. Bdellium has an odour and taste like those of myrrh, but weaker. It is infusible, and inflammable, diffusing while it burns a balsamic odour. According to Pelletier it consists of 59 per cent. of resin, 9.2 of gum, 30.6 of bassorin, and 1.2 of volatile oil including loss. In medical properties it is analogous to myrrh, and was formerly used for the same purposes; but it is now scarcely ever given internally. In Europe it is still occasionally employed as an ingredient in plasters. The dose is from ten to forty grains.

BEAN OF SAINT IGNATIUS. *Faba Sancti Ignatii.* This is the product of the *Ignatia amara* of the younger Linnæus, which is now generally considered by botanists a species of Strychnos, and entitled *S. Ignatia.* (See *Nux Vomica.*) It is a tree of middling size, with numerous long, cylindrical, glabrous, vine-like branches, which bear opposite, nearly sessile, oval, pointed, entire, and very smooth leaves. The flowers are white, tubular, fragrant, and arranged in short axillary racemes. The fruit is of the size and shape of a pear, with a smooth, whitish, ligneous rind, enclosing about twenty seeds embedded in a dry pulpy matter, and lying one upon the other. These seeds are the part used. The tree is a native of the Philippine Islands, where the seeds where highly esteemed as a medicine, and having attracted the attention of the Jesuits, were honoured with the name of the founder of their order.

They are about an inch long, rather less in breadth, still less in thickness, convex on one side, obscurely angular with two, three, or four faces on the other, and marked at one end with a small depression indicating their point of attachment. They are externally of a pale brown colour, apparently smooth, but covered in fact with a short down or efflorescence, which may be removed by scraping them with a knife. They are somewhat translucent, and their substance is very hard and horny. They have no smell, but an excessively bitter taste. To Pelletier and Caventou they afforded the same constituents with the nux vomica, but a much larger proportion of strychnia. (See *Nux Vomica.*) One thousand parts contain twelve of this alkali.

MM. Magendie and Delile have proved that they act on the human system in the same manner as the nux vomica. In the Philippines they have been employed for the cure of obstinate intermittents, and in numerous other diseases. It is probable that in small doses they act as a tonic. In this country they are never employed; nor have they a place in the British Pharmacopœias. We have introduced them here on account of their comparatively large proportion of strychnia, which is triple that contained in the nux vomica. In France they are profitably employed for the extraction of this principle.

BERBERIS VULGARIS. *Barberry.* A shrub growing wild in Europe and the United States, and sometimes cultivated in gardens on account of its berries. These grow in loose bunches, are oblong and of a red colour, have a grateful, sour, astringent taste, and contain malic and citric acids. They are refrigerant, astringent, and antiscorbutic, and are sometimes used in Europe, in the form of drink, in febrile diseases and diarrhœas. An agreeable syrup is prepared from the juice; and the berries themselves are sometimes preserved for the table. The root and inner bark have been used for dyeing yellow, and are said to have been employed beneficially in jaundice. They owe their colouring property to a peculiar crystallizable principle, which has been denominated *berberin.* (*Journ. de Pharm.* xxi. 309.) It is a vulgar error to suppose that the vicinity of this plant is very injurious to wheat. The American plant differs slightly from the European, and is described by Pursh as a distinct species, under the name of *B. Canadensis.* It grows in mountains and hilly districts from Canada to Virginia. The berries are smaller and much less juicy than those of the garden barberry.

BETONICA OFFICINALIS. *Wood betony.* A perennial European herb, belonging to the natural order of labiate plants, the general properties of which it possesses in an inferior degree. It has a pleasant but feeble odour, and a warm, somewhat astringent, and bitterish taste. By the ancients it was very highly esteemed, and employed in numerous diseases; but it is at present little used. It appears to be slightly warming and corroborant, but is inferior in this respect to many other plants belonging to the same family. The root has been considered emetic and purgative.

BETULA ALBA. *Common European birch.* Various parts of this tree have been applied to medical uses. The *inner bark*, which is bitterish and astringent, has been employed in intermittent fever. The epidermis is separable into thin layers, which may be employed as a substitute for paper, and are applied to various economical uses. It contains a peculiar principle, called *betulin*, which may be separated by heat. This is in white, loose, cotton-like flakes, which are volatile, and when heated exhale a peculiar aromatic odour. When the bark is distilled, this principle is decomposed, and affords an empyreumatic volatile oil, having the peculiar odour of Russia leather, in the preparation of which it is employed. The *leaves*, which have a peculiar, aromatic, agreeable odour, and a bitter taste, have been employed in the form of infusion, in gout, rheumatism, dropsy, and cutaneous diseases. The same complaints, particularly dropsy, are said to have been successfully treated by enveloping the body in the fresh leaves, which thus applied excite perspiration. When the stem or branches of the tree are wounded, a sweet *juice* flows out, which is considered useful in complaints of the kidneys and bladder. In consequence of the sugar it contains, it is susceptible, upon the addition of yeast, of the vinous and subsequently of the acetous fermentation. A beer, wine, vinegar, and spirit are prepared from it, and habitually used in some parts of Europe.

Of the American species of birch, the *Betula lenta*, variously called *sweet birch, black birch, cherry birch*, aud *mountain mahogany*, is remarkable for the aromatic flavour of its bark and leaves, which have the odour and taste of the Gaultheria procumbens, and are sometimes used in infusion, as an agreeable, gently stimulant, and diaphoretic drink. This species also affords a saccharine liquor, which, indeed, appears to be common to all the birches. The bark of the *B. papyracea* very closely resembles that of the common European birch, and is much employed by the Northern Indians for making canoes. Thin layers of the epidermis may be advantageously placed inside of boots to prevent the access of moisture.

BEZOAR. This name has been applied to concretions which form in the stomach or intestines of animals, and which were at one time thought to possess extraordinary medical virtues. Numerous varieties have been noticed; but they were arranged in two classes, the *oriental bezoars* (*Lapis bezoar orientalis*), and *western bezoars* (*lapis bezoar occidentalis*), of which the former were most highly esteemed. They have fallen into merited neglect.

BIRD-LIME. A viscid substance existing in various plants, particularly in the bark of the *Viscum album*, and *Ilex aquifolium* or European holly, from the latter of which it is usually procured. The process for preparing it consists in boiling the middle bark for some hours in water, then separating it from the liquid, and placing it in proper vessels in a cool situation, where it is allowed to remain till it becomes viscous. It is then washed to separate impurities, and constitutes the substance in question. Bird-lime thus prepared is greenish, tenacious, of a glutinous consistence, of a bitterish taste, and of an odour analogous to that of flaxseed oil. Exposed to the air in thin layers it becomes dry, brown, and pulverizable, but reacquires its viscidity upon the addition of water. It consists of several proximate principles, but is thought to owe its characteristic properties to the presence of a peculiar substance, identical with that which exudes spontaneously from certain plants, and which has received the name of *glu* from the French chemists. This principle is without odour or taste, extremely adhesive, fusible by heat, inflammable, insoluble in water, nearly insoluble in alcohol, but dissolved freely by sulphuric ether, and the oil of turpentine. According to M. Macaire, it is insoluble in the fixed oils, either hot or cold. This property distinguishes it from the resins, to which Berzelius is disposed to attach it. M. Macaire proposes for it the name of *viscin*. (*Journ. de Pharm.* xx. 18). Bird-lime is so tenacious, that it may be employed to catch small birds, which, when they alight on a stick thickly covered with it, are unable to escape.

BOLE ARMENIAN. The term *bolus* or *bole* was formerly applied to various forms of argillaceous earth, differing in their colour, or place of origin. Thus we find mentioned, among others, the *Armenian, Lemnian*, and *French boles*, and the *red* and *white boles*. Some of these substances were so highly valued as to be formed into small masses and impressed with a seal, and hence received the name of *terræ sigillatæ*. They were all similar in effect, though the small proportion of oxide of iron contained in the coloured boles may have given them greater activity. The only one at present kept in the shops is that called *bole Armenian*, from its resemblance to the substance originally brought from Armenia. It is prepared by trituration and elutriation from certain native earths existing in different parts of Europe. It is in pieces of various sizes, of a reddish colour, soft and unctuous to the touch, adhesive to the tongue, and capable of mixing with water so as to form a paste. It consists chiefly of alumina and silica, coloured with oxide of iron. The boles were formerly employed as absorbent medicines and astringents; and they were undoubtedly useful in some cases of acidity of stomach and relaxed bowels; but they have been superseded by more active medicines. The *bole Armenian* is now used chiefly as an ingredient in tooth powders.

BORAGO OFFICINALIS. *Borage.* This is an annual, hairy, succulent European plant, one or two feet high, with fine blue flowers, on account of which it is sometimes cultivated in our gardens. All parts of it abound in mucilage, and the stem and leaves contain the nitrate of potassa with other saline ingredients. To these constituents the plant owes all its virtues. It is much used in France. An infusion of the leaves and flowers, sweetened with honey or syrup, is employed as a demulcent, refrigerant, and gently diaphoretic drink in catarrhal affections, rheumatism, diseases of the skin, &c. The expressed juice of the stem and leaves is also given in the dose of from two to four ounces. The flowers are sometimes applied externally as an emollient. A distilled water, extract, and syrup were formerly used, but have fallen into neglect. Borage is scarcely known in this country as a medicinal plant, and is altogether too feeble to merit much attention.

BRAZIL WOOD. A red dye-wood, the product of different species of Cæsalpina, growing in the West Indies and South America. Two varieties are known in commerce:— 1. the proper Brazil wood, said to be derived from the *Cæsalpina echinata*, and sometimes called *Pernambuco* or *Fernambuca wood*, from the province of Brazil where it is collected; 2. the *brasilleto*, produced by the *C. Braziliensis* and *C. Crista*, which grow in Jamaica and other parts of the West Indies. The former is the most highly valued. The *sappan* or *sampfen wood* may be referred to the same head, being obtained from the *Cæsalpina Sappan*, and possessing properties analogous to those of the brasilleto. The *Nicaragua* or *peach wood* is also analogous to the *brasilleto*, and is said by Bancroft to be derived from a species of Cæsalpina. It is produced in the East Indies. Brazil wood is nearly inodorous, has a slightly sweetish taste, stains the saliva red, and imparts its colouring matter to water. It was formerly used in medicine; but has been abandoned as inert. In pharmacy it sometimes serves to colour tinctures, &c.; but its chief use is in dyeing. A red lake is prepared from it, and it is an ingredient in a red ink.

BROMINE. *Brominum.* This is an elementary body, possessing many analogies to chlorine and iodine. It was discovered in 1826 by Balard, a chemist of Montpelier, in the bittern of sea-salt works, in which it exists as a bromide of magnesium. Since then it has been discovered in the waters of the ocean, in certain marine animals and vegetables, in numerous salt springs, both in Europe and America, and in two instances in the mineral kingdom—in an ore of zinc, and in the cadmian of Silesia. In the United States it was first discovered by Professor Silliman, who found it in the bittern of the salt works at Salina, in the State of New York, where it exists apparently in considerable quantities. It has been detected also in the waters of the Saratoga Springs, and by Professor Emmet of the University of Virginia, in the Kenhawa water.

Preparation. Pass a current of chlorine through bittern, and then agitate it strongly with a portion of ether. The chlorine decomposes the bromide of magnesium, forming a chloride of magnesium, and disengaging the bromine, which dissolves in the ether and communicates to it a hyacinth-red colour. Decant the ethereal solution of bromine, and treat it with a concentrated solution of caustic potassa. The alkali is converted into bromide of patassium and bromate of potassa, while the ether loses its colour and becomes pure, and may be employed anew in dissolving fresh portions of bromine. Having in this way obtained a sufficient quantity of the salts above mentioned, their solution is evaporated to dryness, and the dry mass calcined at a red heat to convert the bromate of potassa into the bromide of potassium. Next decompose the bromide by distilling it with sulphuric acid and the peroxide of manganese, from a retort furnished with a bent tube, plunging into water contained in a bottle. The acid combines with potassium and oxygen so as to form sulphate of potassa, and the liberated bromine distils over, and condenses under the water.

Properties. Bromine is a liquid of a dark red colour when viewed in mass, but hyacinth-red in thin layers. Its taste is very caustic, and its smell powerful and disagreeable, having some resemblance to that of chlorine. Its density is very nearly 3. At — 4° it becomes a hard, brittle, crystalline solid, having a dark leaden colour, and a lustre nearly metallic. It boils at about 117°, forming a reddish vapour, resembling that of nitrous acid, and of the sp. gr. 5.39. It evaporates readily, a single drop being sufficient to fill a large flask with its peculiar vapour. This vapour extinguishes flame, but previously communicates to it a greenish colour at its base, and a red one above.

Bromine is sparingly soluble in water to which it communicates an orange colour, but is very soluble in alcohol, and especially in ether. The alcoholic and ethereal solutions lose their colour in a few days and become acid from the generation of hydrobromic acid. It bleaches vegetable substances like chlorine, and decomposes organic matters, such as wood, cork, resins, volatile oils, &c. Its combination with starch has a yellow colour. It corrodes the skin and gives it a deep yellow stain.

Bromine is intermediate in its affinities between chlorine and iodine; since its combinations are decomposed by chlorine, while in its turn, it decomposes those of iodine. Its equivalent number is 78.4. It forms acids with oxygen and hydrogen, called bromic and hydrobromic acids, which are analogous both in properties and composition to the corresponding compounds of chlorine and iodine. In testing for bromine in mineral or saline waters, the water is evaporated in order to crystallize most of the salts. The solution, after having been filtered, is placed in a narrow tube, and a few drops of strong liquid chlorine are added. If this addition produces an orange colour, bromine is present. The water, in order that the test may succeed, must be free from organic matter, and the chlorine not added in excess.

Medical Properties. Bromine, from its analogy to iodine, was early tried as a remedy; and the results of these trials have demonstrated its value as a therapeutic agent in certain forms of disease. It probably acts like iodine, by stimulating the lymphatic system and promoting absorption, but is generally supposed to possess more energy. By Magendie it has been employed chiefly as a remedy for scrofula, as an emmenagogue, and in hypertrophy of the ventricles. This physician recommends its employment in cases, in which iodine does not operate with sufficient activity, or has lost its effect by habit. It has been employed in aqueous solution, and in the form of the bromides of potassium, iron, and mercury. The dose of the aqueous solution, containing one part of bromine to forty of distilled water, is about six drops taken in the course of the day The bromide of potassium may be given to the extent of twelve grains in 24 hours, dissolved in three or four fluidounces of water, sweetened with syrup. The dose of the bromide of iron is a grain, given twice a day, in the form of pill made up with conserve of roses and gum Arabic. This bromide is obtained by heating, under water, equal parts of bromine and iron filings. When the liquid becomes greenish, it is filtered and evaporated to dryness; and the dry mass, again dissolved and evaporated to dryness, gives the bromide. Bromide of iron is a brick-red deliquescent salt, very soluble and extremely styptic. Mercury forms two bromides, a proto and deutobromide. The latter is a corrosive poison, and requires to be given in minute doses. It may be employed in ethereal solution, made by dissolving a grain in a drachm of ether, of which ten, fifteen, or twenty drops may be given daily. For frictions the ointment of bromide of potassium is generally used, made with 34 grains of the salt to the ounce of lard. Of this from half a drachm to a drachm may be rubbed into a scrofulous tumour once in 24 hours. See Magendie's Formulary—Eighth Ed., 1835.

Bromine in an overdose acts as a poison. Its most poisonous combination is perhaps the deutobromide of mercury, for which, as for the deutochloride of the same metal, the best antidote is albumen.

CAHINCA. Though not admitted into the Pharmacopœias, this medicine has recently attracted so much attention as to have just claims to notice in the present work. We prefer the title *Chiococca*, as conforming with the nomenclature of the U. S. Pharmacopœia, which, as a general rule, designates particular vegetable remedies by the name of the genus or species to which the plants producing them belong. *Cahinca* or *caïnca* is a term which has passed into common use from the language of the Brazilian Indians. The Portuguese of Brazil call the medicine *raiz pretta* or black root. When first noticed in Europe, it was supposed to be derived from the *Chiococca racemosa* of Linnæus, which was known to botanists as an inhabitant of the West Indies. But Martius, in his "Specimen Materiæ Medicæ Brasiliensis," describes two other species of Chiococca, the *C. anguifuga* and the *C. densifolia*, which afford roots having the properties of that ascribed to the *C. racemosa;* and as the medicine is brought from Brazil, not from the West Indies, there is reason to believe that it is really derived from one or both of the plants named by that botanist. A. Richard, however, informs us that he has received from more than one source in Brazil, specimens of the *C. racemosa* as the cahinca plant; and it is not impossible that the roots of the three species possess identical properties and are indiscriminately used.

The cahinca root, as found in French commerce, is described by M. Achille Richard in the following terms. "It is of a reddish-brown colour, and consists of cylindrical branches, two or three feet long, of the thickness of a quill or smaller, occasionally putting forth slender and branching fibres, obscurely striated longitudinally, presenting at certain distances small irregular tubercles, and here and there transverse fissures produced by drying. These branches are composed of a very thin whitish bark, covered externally with an adhering brown epidermis, and of an internal ligneous centre, which forms almost the whole mass of the root. The cortical portion, which is of a resinous character, has a bitter disagreeable taste, somewhat acrid and astringent; the ligneous part is quite tasteless. Together with the pieces just described, others are sometimes found, derived either from the branches of the stem above ground, or from those which run along the ground and have taken root. They are distinguishable from the true root by being straighter and more regular, and presenting a medullary canal in their centre. The taste of their cortical portion is much weaker, and they are probably less active." *Elem. d'Hist. Nat. Med.* ii. 331.

A specimen brought into our market as the cahinca, consisted of cylindrical pieces, varying in size from the thickness of a straw to that of the little finger, somewhat bent or contorted, slightly wrinkled longitudinally, with occasional small asperities, internally ligneous, externally covered with a thin brittle reddish-brown bark, having a light brown or brownish ash-coloured epidermis. The virtues of the root reside almost exclusively in the cortical portion. They are extracted by water and alcohol. Cahinca has been analyzed by several chemists. Four distinct principles were discovered in it by Pelletier and Caventou:—1. a crystallizable substance, in which all the bitterness of the root resides; 2. a green fatty matter of a nauseous odour; 3. a yellow colouring matter; and 4. a coloured viscid substance. The crystallizable principle appears to be that in which the medical virtues reside. Under the belief that it is essentially acid, its discoverers have named it *cahincic acid.* It is white, without smell, of a taste at first scarcely perceptible, but afterwards extremely bitter, and slightly astringent, of difficult solubility in water, but readily soluble in alcohol, permanent in the air, and unaltered at the temperature of boiling water. It reddens vegetable blues, and unites with the alkalies, but does not form crystallizable compounds. The form in which it exists in the root is thought to be that of a sub-cahincate of lime.

Medical Properties. Cahinca is tonic, diuretic, purgative, and emetic. In moderate doses it gently excites the circulation, increases the discharge of urine, and produces evacuations from the bowels; but is rather slow in its operation. Like most other diuretics, it may be so administered as to prove diaphoretic, by keeping the skin warm, using warm drinks, and counteracting its purgative tendency. In some patients it occasions nausea and griping pains in the bowels, and in very large doses always acts powerfully both as an emetic and cathartic. In Brazil it has long been used by the natives as a remedy for the poisonous effects resulting from the bites of serpents; and its Indian name is said to have been derived from this property. According to Martius, the bark of the fresh root is rubbed with water till the latter becomes charged with all its active matters; and the liquid, while yet turbid, is taken in such quantities as to produce the most violent vomiting and purging, preceded by severe spasmodic pains. Patrick Brown speaks of the root of the *C. racemosa* as resembling seneka in taste, and as very useful in obstinate rheumatisms. But the virtues of cahinca in dropsy, though well known in Brazil, were first communicated to the European public in the year 1826, by M. Langsdorff, Russian Consul at Rio Janeiro. Achille Richard afterwards published a few observations in relation to it in the *Journal de Chimie Medicale;* and within a few years the medicine has been noticed, and its properties investigated by numerous practitioners. M. François of Paris has contributed more than any other physician to its present reputation as a cure for dropsy. By this gentleman it is considered superior to all other remedies in hydropic complaints. General experience appears to be decidedly in its favour, but by no means to the extent of the partial estimate of Dr. François. The root may possibly take a place among the standard diuretics, but is equally obnoxious with most others to the charge of uncertainty. It may be employed in substance, decoction, extract, or tincture. The powdered bark of the root may be given as a diuretic and purgative, in a dose varying from a scruple to a drachm; but in this form the remedy is considered very uncertain. The aqueous extract is usually preferred. The dose of this is from ten to twenty grains. An extract is also prepared with diluted alcohol, and given in the same dose. Dr. François recommends that in the treatment of dropsy, a sufficient quantity should be given at once to produce a decided impression, which should afterwards be maintained by smaller doses, repeated three or four times in the twenty-four hours.

CALENDULA OFFICINALIS. *Marygold.* This well known garden plant was formerly much employed in medicine. It has a peculiar, rather disagreeable odour, which is lost by drying, and a bitter, rough, saline taste. Among its constituents is a peculiar principle, called *calendulin,* discovered by Geiger most abundantly in the flowers, and considered by Berzelius as analogous to bassorin, though soluble in alcohol. The plant was thought antispasmodic, sudorific, deobstruent, and emmenagogue, and was given in low forms of fever, scrofula, jaundice, amenorrhœa, and various other complaints. Both the leaves and flowers were used; but the latter were preferred, and were usually administered in the recent state, in the form of tea. An extract was also prepared, and employed with supposed advantage in cancerous and other ulcers, sick stomach, &c. At present marygold is very seldom if ever used in regular practice.

CALOTROPIS GIGANTEA. Brown. *Asclepias gigantea*, Linn. Under the name of *madar*, or *mudar*, the bark of the root of this, and perhaps other analogous plants, has been employed in the East Indies, with great asserted advantage, in numerous complaints. The plant is a native of Hindostan, and has been introduced into the West Indies, where it is now naturalized. The bark, as employed, is destitute of epidermis, of a whitish colour, nearly or quite inodorous, and of a bitter, somewhat nauseous taste. It appears to have the general properties of many other acrid medicines; in small doses, increasing the secretions, and in larger, producing nausea and vomiting. According to Dr. Cassanova, who published an essay upon the subject at Calcutta, it is more especially directed to the skin, the capillaries and absorbents of which it stimulates to increased action. It is chiefly recommended as a remedy in the obstinate cutaneous diseases of tropical climates, such as elephantiasis and leprosy. It has been employed also with advantage in syphilis, dropsy, rheumatism, and hectic fever. It is administered in substance in the dose of from three to twelve grains, three times a day, and gradually increased till it affects the system.

CAM WOOD. A red dye-wood, procured from the *Baphia nitida* of De Candolle, a leguminous tree, growing on the Western Coast of Africa. The wood is usually kept in the shops in the ground state.

CANARY SEED. The seeds of the *Phalaris Canariensis*, an annual plant, belonging to the family of grasses, originally from the Canary Islands, but now growing wild in Europe and the United States, and cultivated in many places. The seeds are ovate, somewhat compressed, about two lines long, shining and of a light yellowish-gray colour externally, and brownish within. Their chief constituent is starch. They were formerly esteemed medicinal, but are not now employed unless for the formation of emollient cataplasms. They are nutritive, and their meal is said to be mixed, in some places, with wheat flour, and made into bread. They are much used as food for Canary birds.

CANNABIS SATIVA. *Hemp.* An annual plant, originally from Asia, but now cultivated in various parts of Europe and North America. The *leaves* are possessed of narcotic properties, and are employed in Persia and the East Indies, in the form of infusion, as an intoxicating drink. They are also smoked, in these and other countries of the East, for the same purposes as tobacco, with which they are frequently mixed. An extract prepared from them is said to produce effects analogous to those of opium. Even the odour of the fresh plant is stated to be capable of producing vertigo, headach, and a species of intoxication. The *seeds* have been used in medicine. They are about the eighth of an inch long, roundish-ovate, somewhat compressed, of a shining gray colour, inodorous, and of a disagreeable, oily, sweetish taste. They contain a considerable quantity of fixed oil, which is separated by expression, and used to some extent in the arts. They contain also uncrystallizable sugar and albumen, and when rubbed with water afford an emulsion, which may be used advantageously in inflammatory affections of the mucous membranes, though it is not superior to a similar preparation from other emulsive seeds. They are much used as food for birds, which are fond of them. It is, however, for the fibrous bark of hemp, and the various products manufactured from it, that the plant is chiefly cultivated.

CAOUTCHOUC. *Gum elastic.* The substance known by this name in commerce is the concrete juice of the *Siphonia Cahuchu* of Schreber and Willdenow, identical with the *Siphonia elastica* of Persoon, the *Jatropha elastica* of the younger Linnæus, and the *Hevea Guianensis* of Aublet. This is a large tree growing in Brazil, Guiana, and probably also in Central America. (*Journ. Phil. Col. of Pharm.* iii. 292.) On being wounded it emits a milky juice, which concretes on exposure, and constitutes the substance in question. A similar product is afforded by several other lactescent plants; but the juice of the Siphonia alone is extensively collected for use. Caoutchouc comes to us in different forms, sometimes in large flat pieces, sometimes in the shape of various animals, but usually in that of small flasks. These are formed by applying successive layers of the juice upon models of clay, which are broken and removed when the coating has attained a sufficient thickness and consistence. In the drying of these layers they are said to be exposed to smoke, which gives to the concrete mass a blackish colour. The juice, when it concretes by exposure to the air, assumes on the outer surface a yellowish-brown colour, while the mass remains white or yellowish-white within. The recent juice is not a pure proximate principle; but contains, according to Faraday, 1.9 per cent. of vegetable albumen, traces of wax, 7.13 per cent. of a bitter azotized substance soluble in water and alcohol, 2.9 of a substance soluble in water but insoluble in alcohol, 56.37 of water with a little free acid, and only 31.7 of the pure elastic principle to which chemists have given the name of caoutchouc. Some of these principles exist also in greater or less proportion in the concrete juice, which, as it reaches us, is usually contaminated with the soot derived from the smoke used in drying it. *Pure caoutchouc* is nearly colourless, and in thin layers transparent. It is highly elastic, lighter than water, without taste and smell, fusible at about 248°, remaining unctuous and adhesive upon cooling, inflammable at a higher temperature, insoluble in water, alcohol, the weak acids, and alkaline solutions, soluble in ether when entirely freed from alcohol, soluble also in most of the fixed and volatile oils, though at the expense of its elasticity. It is said, however, that the oils of lavender and sassafras dissolve it without change, and that when precipitated by alcohol from its solution in cajuput oil, it is still elastic. It is not affected by common air, chlorine, muriatic or sulphurous acid gas, nor by ammonia. It consists, according to Faraday, of 87.2 parts of carbon, and 12.8 of hydrogen.

Caoutchouc is used for erasing pencil marks; in the formation of flexible tubes for the laboratory, and of catheters and bougies for surgical purposes; in the melted state, as a luting to the joints of chemical apparatus; in the shape of thin layers, for covering the mouths of bottles, and for other purposes in which the exclusion of air and moisture is requisite; in the manufacture of water-proof cloth; and for numerous other objects, to which its elasticity, and the resistance which it offers to the ordinary solvents and to other powerful chemical agents peculiarly adapt it. Every one is aware of the highly important application which has recently been made of caoutchouc to the manufacture of water-proof shoes. It is most conveniently brought to the state of thin layers, in which it may often be used advantageously by the chemist and apothecary, by softening the small flasks in ether containing alcohol, or by boiling them in water for fifteen minutes, and then distending them by means of air forced into them. Tubes of caoutchouc may be made from its ethereal solution, or from the juice imported in the liquid state.

CAPPARIS SPINOSA. *Caper-bush.* A low, trailing shrub, growing in the South of Europe and North of Africa. The buds or unexpanded flowers, treated with salt and vinegar, form a highly esteemed pickle, which has an acid burning taste, and is considered useful in scorbutic affections. The dried bark of the root was formerly officinal. It is in pieces partly or wholly quilled, about one-third of an inch in mean diameter, transversely wrinkled, grayish externally, whitish within, inodorous, and of a bitterish, somewhat acrid and aromatic taste. It is considered diuretic, and was formerly employed in obstructions of the liver and spleen, amenorrhœa, and chronic rheumatism.

CARANNA. *Gum caranna.* A resinous substance, in pieces of a blackish-gray colour externally, dark-brown internally, somewhat shining and translucent, brittle and pulverizable when dry, but, in the recent state, soft and adhesive like pitch, easily fusible, of an agreeable balsamic odour when heated, and of a bitterish resinous taste. (*Geiger.*) It is said to be derived from the *Amyris Carana* of Humboldt, a tree growing in Mexico and South America. Geiger refers it also to the *Bursera gummifera* of the West India Islands; but the resin obtained from this tree is described by the French writers under the name of *resine de Gomart* or *resine de chibou ou cachibou*, and is said to bear a close resemblance to the resin *tacamahac.*

CATALPA CORDIFOLIA. *Bignonia Catalpa.* Linn. *Catalpa tree*, or *Catawba tree.* This is a beautiful flowering tree, growing wild in this country, and occasionally cultivated for ornamental purposes. It has been introduced into the gardens of Europe. It is commonly reputed to possess poisonous properties. The seeds have been advantageously employed by several practitioners of Continental Europe in asthma. M. Automarchi recommends a decoction made by boiling twelve ounces of water with three or four of the seeds down to six ounces, the whole to be given morning and night. (*Journ. of the Phil. Col. of Pharm.* vi. 352.)

CEANOTHUS AMERICANUS. *New Jersey tea. Red root.* A small indigenous shrub, growing throughout the United States. The root is astringent, and imparts a red colour to water. It is said to be useful in syphilitic complaints, in which it is given in the form of decoction, made in the proportion of two drachms of the root to a pint of water. Schoepf states that it is purgative. The leaves were used during the revolutionary war as a substitute for tea. Dr. Hubbard, in a communication to the Boston Medical and Surgical Journal, (Sept. 30th, 1835,) speaks very highly of the use of the Ceanothus as a local application in aphthous affection of the mouth and fauces, and in the sorethroat of scarlatina, and as an internal remedy in dysentery. He used a strong infusion of the dried leaves and seeds.

CHÆROPHYLLUM SATIVUM. *Chervil.* An annual European plant, cultivated in gardens as a pot-herb, and supposed by some physicians to possess medicinal powers. It has a strong agreeable odour, especially when rubbed, and a pungent slightly bitterish taste. These properties it owes to a volatile oil, which may be separated by distillation with water. It is said to be deobstruent, diuretic, and emmenagogue, and has been recommended by different authors in consumption, scrofula, dropsy, cutaneous and scorbutic affections, and as an external application to swollen breasts, bruises, and other local complaints or injuries. It is, however, a very feeble remedy, and is more employed as an addition to broths than as a medicine.

CHELIDONIUM MAJUS. *Celandine.* A perennial herbaceous plant, growing wild in this country, about old houses and in rocky places; but supposed to have been introduced from Europe, where it is indigenous. It is one or two feet high, bears pinnate leaves and small peduncled umbels of yellow flowers, and, when wounded, emits a yellow, opaque juice. It was employed by the ancients, and is occasionally used in modern practice, but little on this side of the Atlantic. The whole plant is used. It has a faint unpleasant odour, and a bitter, acrid, durable taste, which is stronger in the roots than in the leaves. The odour is nearly lost by drying, but the taste remains. The yellow juice is bitter and exceedingly acrid, and when applied to the skin produces inflammation and even vesication. The plant, analyzed by MM. Chevallier and Lassaigne, afforded a bitter resinous substance of a deep yellow colour; a kind of gum-resin of an orange-yellow colour, and bitter, nauseous taste; mucilage; albumen; and various saline substances, besides free malic acid and silica. Celandine is an acrid purgative, possessed also of diuretic, and perhaps diaphoretic and expectorant properties. In over doses, it produces unpleasant effects, and is by some considered poisonous. By the ancients it was much esteemed as a remedy in jaundice: and it has been found useful in the same complaint by some modern physicians. It was the chief ingredient of the old *decoctum ad ictericos* of the Edinburgh Pharmacopœia. It has been given also, with asserted advantage, in various other complaints, especially those of a scrofulous character, affecting the mesenteric and lymphatic glands, the skin, and the eyes. The yellow juice is often applied, in domestic practice, to corns and warts, which it destroys by stimulating them beyond their vital powers. The dose of the dried root or herb is from thirty grains to a drachm, that of the fresh root one or two drachms; and the same quantity may be given in infusion. The watery extract and the expressed juice have also been employed. The dose of the former is from five to ten grains, that of the latter from ten to twenty drops. In each case, the dose is to be gradually increased, until the effects of the remedy are experienced.

CHELTENHAM SALT, ARTIFICIAL. Several artificial mixtures have been prepared, professing to be exact imitations of the saline ingredients in the chalybeate Cheltenham water; but the only one which appears worthy of confidence, is that prepared by Robert Alsop, Chemist, of London. The composition of the natural Cheltenham chalybeate is given at p. 103, under the head of *Aqua.* The imitation of Mr. Alsop, as analyzed by Mr. Faraday, contains the same solid and gaseous contents as the natural water, except the sulphate of lime, which is very properly omitted; and in the same proportions precisely, with the exception that there is about twice as much free carbonic acid in the artificial preparation. The iron is present in the state of protoxide, and is immediately dissolved by the free carbonic acid, upon adding a sufficient quantity of water to the mixed salts. The free carbonic acid probably exists as such in the dry mixture; as there is no obvious agent present to cause it to be disengaged in the mere act of solution.

This saline mixture is in the form of a white powder, possessing a saline and slightly ferruginous taste. It is put up in bottles of two sizes, the smaller containing two and a half ounces, or sufficient to make thirty doses of forty grains each. It forms a good combination, in which the aperient property of the salts present is combined with the tonic virtue of the iron. It is considered to be useful in glandular obstructions, especially of the liver, and in scrofulous affections, attended with feeble digestion, sluggish bowels, and pallidness of skin. It is employed also, with advantage, in sick headach, habitual costiveness, and hemorrhoids. The dose is a teaspoonful, quickly dissolved in half a pint of cold water, and swallowed immediately, before the iron has time to separate in an insoluble state. This quantity may be taken in the morning fasting, and repeated once or twice after an interval of twenty minutes, or in the course of the day. To obtain its full tonic and alterative effects, it should be persevered in for a month or six weeks.

CHLORIDE OF LIME. *Oxymuriate of Lime. Bleaching Powder. Calcis Chloridum.* This compound is introduced here on account of its importance as a medicinal and disinfecting agent. It was first prepared, and brought into notice as a bleaching agent, in 1798, by Mr. Tennant of Glasgow. Since that time, ample experience has proved it to be the most convenient combination, by means of which the manufacturer can avail himself of the bleaching powers of chlorine gas; and accordingly vast quantities of it are at present prepared in different countries in which bleaching operations are conducted on an extensive scale.

Preparation. Chloride of lime may be easily prepared on a small scale, by passing a stream of chlorine through the pulverulent hydrate of lime, as long as it continues to be absorbed. On a large scale it is made by means of a great variety of apparatus, but the following, employed at Glasgow, is, according to Dr. Ure, the simplest and best. A large chamber is constructed eight or nine feet high, built of siliceous sandstone, the joints being secured by a cement of pitch, rosin, and dry gypsum. At one end it is furnished with an air-tight door, and on each side, with a glass window, to enable the operator to inspect the process during its progress. The slaked or hydrated lime is sifted and placed on wooden trays, eight or ten feet long, two feet broad and one inch deep. These are piled up within the chamber to the height of five or six feet on cross-bars, which, by keeping them about an inch asunder, favour the circulation of the gas over the lime.

The chlorine is generated in vessels nearly spherical, composed either entirely of lead, or the upper half of lead, and the lower half of iron. The vessel, when all of lead, has its lower two-thirds enclosed in a leaden or iron case, leaving an interstice of two inches in width, intended to receive steam for the purpose of producing the requisite heat. When of the other construction, the iron hemisphere has cast round its outer edge a groove, in which the lower edge of the leaden hemisphere rests, and is secured by Roman cement. The heat, in this case, is applied by exposing the bottom of the iron vessel directly to a gentle fire. In the leaden hemisphere are four apertures. The first is about ten or twelve inches square, and is closed by a leaden valve, the incurvated edges of which rest in a groove which is on the margin of the opening and filled with water: this aperture is intended to facilitate the adjustment of any interior derangement of the apparatus. The second aperture is in the centre of the top, and receives a tube which descends nearly to the bottom, and through which a vertical stirrer passes, intended to mix the materials, and furnished at the lower end with horizontal cross-bars of iron, or of wood sheathed with lead. A rotary motion is given to the stirrer, either by a winch turned by hand, or by steam or water power. The third opening admits a syphon-shaped funnel, through which the sulphuric acid is introduced, and the fourth is connected with a pipe intended to lead off the gas.

The pipes passing from the different generating vessels all terminate under water contained in a leaden chest or cylinder, where the gas, by passing through this liquid, is washed from muriatic acid. From this intermediate vessel, the chlorine finally passes, by means of a pretty large leaden pipe, through the ceiling of the chamber containing the lime. The process of impregnation generally requires to be continued four days, in order to form a good bleaching powder. If the process be hastened, heat will be generated, which will favour the production of muriate of lime, attended with a proportional diminution of the chloride.

The proportions of the materials employed for generating the chlorine vary in different manufactories. Those generally adopted, are 10 cwt. of salt, mixed with from 10 to 14 cwt. of peroxide of manganese; to which are added, in successive portions, from 12 to 14 cwt. of strong sulphuric acid, diluted before being used until its sp. gr. is reduced to about 1.65, which will be accomplished by adding about one-third of its weight of water. In manufactories in which sulphuric acid is also made, the acid intended for this process is brought to the sp. gr. of 1.65 only, whereby the expense of further concentration is saved.

The nature and composition of chloride of lime are not well settled. From the analyses which we possess, it appears very variable in quality, containing more or less loosely combined chlorine. From the results of Dr. Ure, it may be inferred, that, in the commercial samples of this compound, the chlorine is combined with between three and four times its weight of hydrate of lime. Hence it is easy to make a rough calculation of the quantity of the chloride which should result from the use of a ton of common salt. In this quantity of salt there are six-tenths of a ton of chlorine, which, if combined with three times its weight of hydrated lime, would furnish two and four-tenths of a ton of the compound. But in practice, the manufacturer gets only a ton and a half of good bleaching powder by the use of a ton of rock salt, instead of the quantity above indicated. The deficit arises, in a great degree, from the unavoidable loss of chlorine, both from its imperfect liberation from the salt, and from its waste in the combining chamber; but it is probably greater than it would be, if science directed the operation.

The mode in which chloride of lime is manufactured in this country, corresponds, in the general outline, with that pursued in Scotland, as above described.

Properties. Chloride of lime is a dry grayish-white pulverulent substance, possessing a hot penetrating taste, and a feeble odour of chlorine. When perfectly saturated with chlorine, it dissolves almost entirely in water; but as ordinarily prepared, a large proportion is insoluble, consisting of hydrate of lime, containing a small portion of chlorine. When exposed to heat it gives out oxygen and a little chlorine, and is converted into chloride of calcium. By the action of acids, however, the chlorine is disengaged, and hence this addition gives activity to the substance as a bleacher and disinfector. By exposure to the air it absorbs moisture and deteriorates, being converted in part into muriate, at the expense of the chloride of lime. When moist, it is of inferior quality, as this circumstance indicates the presence of muriate of lime.

As chloride of lime is very variable in its quality, it becomes important to possess the means of testing its value. Welter proposed for this purpose a weak solution of indigo in sulphuric acid. It is used by observing what proportion of a solution obtained from a given weight of the chloride is necessary to discharge the colour of a solution of indigo of a determinate strength; and the value of the sample is inversely as this quantity. Of course, in making comparative experiments of this kind, care must be taken that the sulphate of indigo is of uniform strength, and that the solution obtained from the different samples of chloride is made under similar circumstances. Another test, which was proposed by Mr. Dalton, is to add a solution of the bleaching powder to one of protosulphate of iron until the smell of chlorine is perceived; and the value of the sample will be in proportion to the smallness of the quantity of the solution, necessary to produce this effect. Dr. Thomson reports, that Mr. Crum, a practical chemist of Glasgow, finds this method exact in its indications.

Composition. Notwithstanding the bleaching powder has been studied by a number of able chemists, its composition is still involved in doubt. At first it was asserted to be a compound of one equivalent of chlorine with two of lime in the state of hydrate. Dr. Ure contends that the lime and chlorine are united in variable proportions, not correspondent to equivalent quantities; but Dr. Thomson asserts that the compound has been so much improved in quality of late years, that good specimens are almost entirely soluble in water, and consist of one equiv. of chlorine 35.42, and one equiv. of lime 28.5 = 63.92. Berzelius, however, takes a different view of the composition of this compound. He considers it to be a combination of tritoxide of chlorine, which he calls *chlorous* acid, with lime. According to this view, then, it is a *chlorite of lime.*

Medical Properties and Uses. Chloride of lime is a powerful disinfecting agent, and has been used with advantage in solution as an application to ill-conditioned ulcers, burns, and cutaneous eruptions, as a gargle in putrid sorethroat, and as a wash for the mouth to disinfect the breath, and for ulcerated gums. As it occurs of variable quality in commerce, and must be used in solution more or less dilute according to the particular purpose to which it is to be applied, it is impossible to give any very precise directions for its strength as a therapeutical agent. From one to four drachms of the powder added to a pint of water and filtered, will constitute a solution within the limits of strength ordinarily required. For the cure of itch, M. Derheims has recommended a much stronger solution—three ounces of the chloride to a pint of water, the solution being filtered, and applied several times a day as a lotion. When applied to ulcers, their surface may be covered with lint dipped in the solution. This preparation acts, without doubt, by means of the chlorine which it contains; but is not so eligible, perhaps, for external use or internal exhibition, as the compound of analogous constitution, called *chloride of soda.* (See the next article.)

In consequence of its powers as a disinfector, chloride of lime is a very important substance in its application to medical police. It possesses the extraordinary property of preventing or arresting animal and vegetable putrefaction, and of destroying pestilential and infectious miasms. It is consequently applicable to a great variety of purposes, more or less connected with the health or comfort of communities. It may be used with advantage for preserving bodies from exhaling an unpleasant odour before interment in the summer season. In juridical exhumations, its use is indispensable, as it effectually removes the disgusting and insupportable fetor of the corpse. The mode in which it is applied in this case, is to envelop the body with a sheet completely wet with a solution, made by adding about a pound of the chloride to a bucketful of water. It is employed also for disinfecting dissecting rooms, privies, common sewers, docks, and other places which exhale offensive effluvia. In destroying contagion and infection, it also appears to be highly useful. Hence hospitals, alms-houses, jails, ships, &c., may be purified by its means. In short, all places which may be deemed infectious, from having been the receptacle of cases of virulent disease, may be more or less disinfected by its use, after they have undergone the ordinary processes of cleansing.

The way in which chloride of lime acts, is exclusively by means of its chlorine, which, being loosely combined, is disengaged by the slightest affinities. All acids, even the carbonic, disengage it; and as this acid is a product of animal and vegetable decomposition, noxious effluvia furnish the means, to a certain extent, of their own disinfection by this chloride. But the stronger acids disengage the chlorine far more readily; and among these, sulphuric acid is the cheapest and most convenient. Accordingly the chloride of lime may be dissolved in a very dilute solution of sulphuric acid, or a small quantity of this acid may be added to a solution of the chloride, in case a more copious evolution of chlorine is desired than that which takes place from the mere action of the atmosphere. Another way of effecting the same object, which is commended by Berzelius, is to mix the chloride with the bisulphate of potassa in powder, in which case it is only necessary to moisten the mixture to disengage the chlorine. The bisulphate, being a supersalt, here acts the part of an acid.

Chloride of lime may be advantageously applied to the purpose of purifying offensive water, a property which makes it invaluable on long voyages. When used for this purpose, from one to two ounces of the chloride may be mixed with about sixty-five gallons of the water. After the purification is effected, the water must be exposed for some time to the air and allowed to settle before it is fit to drink. For further details the reader is referred to an interesting article, by Mr. Elias Durand, on the chlorides of oxides, contained in the first vol. of the Journ. of the Phil. Col. of Pharm.

CHLORIDE OF POTASSA. *Javelle's Water. Eau de Javelle. Liquor Potassæ Chloridi.* This is obtained precisely as the chloride of soda, described in the next article. It is employed for taking out fruit stains, &c., from linen. In chemical constitution, it is deemed a *chlorite.*

CHLORIDE OF SODA. *Labarraque's Disinfecting Soda Liquid. Liquor Sodæ Chloridi.* This compound was first brought into notice as a disinfecting agent by Labarraque, an apothecary of Paris, who announced it to be a combination of chlorine with soda, analogous to the chloride of lime. Its nature has since been investigated by Phillips and Faraday, especially by the latter, who considers it not to be exclusively a chloride of soda; but a combination of this chloride, which is its active ingredient, with a certain portion of carbonate of soda.

Preparation. In preparing the chloride of soda, it is necessary, in order to have a good preparation, to follow the proportions recommended by Labarraque. He dissolves 15 parts of carbonate of soda in 40 parts of water, and passes through the solution all the chlorine generated by a mixture of 2 parts of peroxide of manganese, and 6 parts of muriatic acid of commerce. The chlorine should be passed through water to free it from muriatic acid. During the continuance of the process no carbonic acid is evolved.

Another process for obtaining the chloride of soda, more easy of execution than the above, is that proposed by M. Payen. It consists in decomposing the chloride of lime by carbonate of soda. By double decomposition, chloride of soda and carbonate of lime are formed, the latter of which separates in consequence of its insolubility. The proportions directed by M. Payen are, a pound of dry chloride of lime, two pounds of crystallized carbonate of soda, and eighteen pounds of water. The chloride is dissolved in twelve pounds of water, which is added by small successive portions, and the solution obtained allowed to settle for three hours in a covered vessel; after which it is decanted clear, and filtered. The insoluble portion is now thrown upon a filter, and exhausted by two successive additions of water of two pounds each. The carbonate of soda is now dissolved, by the assistance of heat, in two pounds of water, and the solution having been allowed to grow cold, is mixed with that of the chloride of lime. An abundant precipitate of carbonate of lime is immediately formed, from which the solution of chloride of soda, simultaneously generated, is decanted. This is then filtered and introduced into bottles, which should be carefully stopped. The quantities of the materials above indicated, yield about two gallons and a half of the liquid chloride of soda.

Properties. Labarraque's soda liquid has a pale yellow colour, and a slight odour of chlorine. Its taste is sharp, saline, and but feebly alkaline, producing a persisting biting impression on the tongue. It possesses an alkaline reaction. When boiled, chlorine is not given off, nor is its bleaching property sensibly impaired; and if carefully evaporated, a mass of damp crystals will be obtained, which, when redissolved in water, will possess the properties of the original liquid. When long kept it undergoes alteration, from the generation of chloric acid and chloride of sodium.

Composition. The nature of Labarraque's liquid is still involved in doubt. It seems to be conceded, however, that it is not a pure chloride of soda, as it contains carbonic acid as well as the constituents of that combination. Berzelius takes the same view of it as he does of the chloride of lime; namely, that it is a compound of chlorous acid (tritoxide of chlorine) and soda. He accordingly calls it *chlorite of soda.* (See *Chloride of Lime.*) Dr. Turner has thrown out the conjecture that the chlorine, in this preparation, combines with half the soda; while the other half, with all the carbonic acid, constitutes a bicarbonate. On this view of its composition, Labarraque's liquid is a combination of chloride and bicarbonate of soda.

Medical Properties and Uses. Chloride of soda is a powerful disinfectant, possessing in this respect the same general properties as the chloride of lime. It is, however, much better suited for disinfecting operations; as it does not, when exposed to air, become covered with a crust of carbonate of lime, an objection to which the solution of the bleaching powder is liable. It was first introduced to the notice of the French practitioners by Labarraque; and the experience already had of its powers in various affections, has been sufficient to establish its remedial value. Its principal medical use is as an external application, though occasionally it is given internally. The external affections in which it has been found useful are, generally, all those attended with fetor; such as gangrenous and ill-conditioned ulcers, ulcerations of the gums, carbuncle, cancer, ozæna, mortification, putrid sorethroat, &c. It is applied, in such cases, in a more or less dilute state, as a wash, mixed with poultices, or imbibed by lint. In the sore mouth from ptyalism, it forms a good mouth-wash, when diluted with eight parts or more of water. In fetid discharges from the uterus and bladder, it has been employed with advantage as an injection, diluted with from fifteen to thirty parts of water for the uterus, and with sixty parts when the object is to wash out the bladder by means of a double cannula. The chloride has also been applied successfully to burns, and to cutaneous eruptions, particularly tinea capitis, and obstinate herpetic affections. Internally it has been exhibited in scarlatina maligna, in dysentery attended with peculiarly fetid stools, in those forms of dyspepsia attended with putrid eructations, and in asphyxia produced by sulphuretted hydrogen. The dose is from fifteen to twenty-five drops in a cupful of water, repeated every two or three hours.

As a disinfecting agent, chloride of soda is more valuable than the chloride of lime; but its comparative expensiveness will restrict its use to disinfecting operations on a small scale. In the bed chambers of the sick, especially with infectious diseases, it will be found highly useful, sprinkled on the floor or bed, and added to the vessels intended to receive the excretions. In short, it is applicable to most of the disinfecting purposes detailed under the head of ***chloride of lime***, to which article the reader is referred.

CHLORINE ETHERS. There appear to be three species of chlorine ether, each consisting of some form of hydro-carbon, united with different proportions of chlorine. The first is called *protochlorine ether*, and is formed by passing an excess of chlorine through cold alcohol. It consists of one equiv. of chlorine 35.42, and one of etherine 28.48. The second, denominated *bichlorine ether*, consists of two equiv. of chlorine and one of etherine, and is the long known oily liquid of the Dutch chemists, obtained by the action of olefiant gas on chlorine. The third species was discovered within a few years by three chemists, independently of each other—Soubeiran in France, Liebig in Germany, and Guthrie in this country. Dumas has determined its composition to be three equiv. of chlorine to one of bicarburet of hydrogen, and ascertained that it differs from formic acid, into which it is susceptible of conversion by the action of potassa, in containing an equivalent quantity of chlorine, in place of the oxygen of that acid. On account of its connection with formic acid, it is called by the French chemists chloroforme, which may be rendered in English chloroformid. It is this latter compound which it is the object more particularly of this article to describe.

Chloroformid was obtained by Mr. Guthrie by distilling a gallon from a mixture of three pounds of chloride of lime and two gallons of alcohol of sp. gr. 0.844, and rectifying the product by redistillations, first from a great excess of chloride of lime, and afterwards from strong sulphuric acid. Thenard recommends it to be obtained by dissolving one part of chloride of lime in three parts of water, decanting the solution, adding from one-fifth to one-tenth of alcohol, and distilling from a retort sufficiently capacious to guard against the overflowing of the materials when they swell. In the receiver water will condense, swimming over an oleaginous liquid. The water is decanted, and the oily liquid, being agitated several times with concentrated sulphuric acid, and rectified from finely powdered baryta, will furnish pure chloroformid.

This compound is a colourless oleaginous liquid, of a sweetish ethereal odour, and hot, aromatic, peculiar taste. It boils at 142° and has the sp. gr. of 1.480. It is not inflammable, but renders the flame of an alcohol lamp yellow and fuliginous. It is scarcely acted on by sulphuric acid in the cold, but dissolves readily in alcohol and ether, from its solution in which it is precipitated by water. The alcoholic solution, the state in which it is used in medicine, forms, when sufficiently diluted with water, an aromatic and saccharine liquid of a very grateful taste.

Medical Properties. Mr. Guthrie was led to prepare this ether by his peculiar process from noting a passage in Professor Silliman's Elements of Chemistry, which referred to the chloric ether of the Dutch chemists as being a grateful diffusible stimulant, when properly diluted. He supposed that he had fallen upon a cheap and easy process for obtaining this long known ether, without being aware that in reality he had obtained a new compound of the same class. Specimens of it were transmitted to Professor Silliman, who distributed portions among his medical friends. It appears to act as a diffusible soothing stimulus, in the same manner as sulphuric ether, but with this decided advantage, that, when sufficiently diluted, it possesses a bland, sweet taste, which renders its administration easy, even to children. It has been used with advantage in asthma, spasmodic cough, the sorethroat of scarlet fever, atonic quinsey, and other diseases in which a grateful and composing stimulus is indicated. Professor Ives, and Dr. N. B. Ives, of New Haven, speak favorably of its effects. The dose for an adult is a teaspoonful, diluted with water. In affections characterised by difficult respiration, it may be used by inhalation. It is employed for medicinal purposes in alcoholic solution.

CHROME YELLOW. This is the neutral chromate of lead, prepared by precipitating a solution of the nitrate of lead with chromate of potassa. It is of a beautiful lemon-yellow colour. The subchromate of lead, consisting of one equiv. of acid and two equiv. of base, is of a red colour, and is sometimes used as a pigment. *Chrome green* is a mixture of chrome yellow and Prussian blue.

CICHORIUM INTYBUS. *Succory.* A perennial herbaceous plant, indigenous in Europe, but naturalized in this country, where it grows in fields, and in roads along the fences, in neighbourhoods which have been long settled. It is one or two feet high, with large, compound, beautifully blue flowers, which appear in July and August, and serve to distinguish the plant at first sight. The whole plant has a bitter taste, without acrimony, or any very peculiar flavour. The taste is strongest in the root, and weakest in the flowers. The leaves, when young and tender, are said to be sometimes eaten as salad in Europe. Succory is gently tonic without being irritating, and is considered by some authors as aperient and deobstruent. It is said to be useful, if freely taken, in hepatic congestion, jaundice, and other visceral obstructions in the early stages; and it is affirmed to have done good even in pulmonary consumption. The usual form of administration is that of the decoction, which is prepared by boiling one or two ounces of the root, or a handful of the herb, in a pint of water. The root dried and roasted has acquired some popularity, in certain parts of Europe, as a substitute for coffee. The common *garden endive* is a species of Cichorium denominated *C. Endivia.*

CICUTA VIROSA. *Water hemlock. Cowbane.* A perennial, umbelliferous European plant, growing on the borders of pools and streams. It is exceedingly poisonous, proving fatal to most animals which feed upon it, though said to be eaten with impunity by goats and sheep. Several instances are on record of children who have died from eating the root by mistake for parsnip. It operates as an acrid narcotic, producing inflammation of the stomach, together with symptoms which indicate cerebral disturbance, such as vertigo, intoxication, and convulsions. When it vomits, as it frequently does, fatal effects are less apt to ensue. There is reason to believe that the narcotic principle is volatile, and that the plant is less poisonous in the dried than the recent state. It is at present never used internally as a medicine, having been superseded by the *Conium maculatum*, which is considered safer. Externally it is sometimes applied as an anodyne poultice in local pains, particularly those of a rheumatic or gouty nature.

The *Cicuta maculata* or *American water hemlock* is closely analogous, in botanical character, and in its operation upon the system, to the European species. In several instances, children have been fatally poisoned by eating its root. It is never used in medicine. For a full account of this plant, the reader is referred to Bigelow's Medical Botany, vol. i. page 125. In cases of poisoning by either of these plants, vomiting should be induced as speedily as possible, and maintained till the stomach is thoroughly evacuated.

CIVET. *Zibethum.* This is an odorous substance, obtained from two animals of the genus Viverra, viz., the *V. Civetta* or civet-cat of Africa, and the *V. Zibetha* which inhabits the East Indies. It is secreted into a cavity which opens between the anus and external genitals, and is collected from animals confined for the purpose. It is semi-liquid, unctuous, yellowish, becoming brown and thicker by exposure to the air, of a very strong, peculiar odour, similar to that of musk, though less agreeable and less diffusible, and of a bitterish, subacrid, disagreeable, fatty taste. When heated it becomes quite fluid, and at a higher temperature takes fire, and burns with a clear flame, leaving little residue. It is insoluble in water, and only slightly soluble in ether and cold alcohol; but heated alcohol dissolves it almost entirely, depositing it again upon cooling. It contains, among other ingredients, a volatile oil, fat, and free ammonia. In medicine it was formerly employed as a stimulant and antispasmodic, like castor and musk; but it is now used exclusively as a perfume.

CLEMATIS ERECTA. *Upright Virgin's Bower.* A perennial plant, growing wild on the continent of Europe. The leaves and flowers have an acrid burning taste, and if long retained in the mouth produce blisters. When bruised in a mortar they irritate the eyes and throat, giving rise to a flow of tears and to coughing; and applied to the skin they produce inflammation and vesication Hence the name of *flammula Jovis*, by which the plant was known in older pharmacy. The acrimony is greatly diminished by drying. Störck found this species of Clematis very useful in secondary syphilis, cancerous and other foul ulcers, and in severe headachs. He gave it internally, and at the same time applied the powdered leaves to the surface of the sore. It acted as a diuretic and diaphoretic. Two or three drachms of the leaves were infused in a pint of water, of which he administered four ounces three times a day. He also employed an extract, in the dose of a grain or two in the course of a day; but this preparation must have been nearly inert. At present the plant is not used.

Other species of Clematis have the same acrid properties. Among these are the *C. Flammula* or *sweet-scented virgin's bower*, which, though a native of Europe, is cultivated in our gardens, the *C. Vitalba* or *traveller's joy*, also a native of Europe, and several indigenous species, of which the *C. Virginica* or *common virgin's bower*, the *C. Viorna* or *leather flower*, and the *C. crispa*, have been particularly cited by authors as proper substitutes for the C. erecta used by Störck. All these are climbing plants. The C. Vitalba has been used in Europe with success in the cure of the itch. For this purpose the roots and stems, bruised, and boiled for a short time to diminish their acrimony, were infused in boiling oil, which, thus impregnated, was applied to the skin several times a day. Twelve or fifteen applications were usually sufficient to effect a cure.

COBALT BLUE. This beautiful pigment is a compound of oxide of cobalt and alumina, obtained by precipitating the mixed solutions of a salt of alum and of cobalt by means of an alkali, and washing, drying, and strongly calcining the precipitate. (*Berzelius.*) The cobalt blue of Thenard is made by heating together the hydrated subphosphate of cobalt and hydrate of alumina. It is used in painting.

COBWEB. *Spider's Web. Tela Araneæ.* The genus *Aranea* of Linn. has been divided by subsequent naturalists into several genera, of which the *Tegeneria* of Walkenaer is the one that includes the medicinal species of spider. The *T. domestica* of Europe, and *T. medicinalis* of this country, (Henz, *Journ. Acad. of Nat. Scien.* ii. 53,) are the particular species which have attracted most attention. They inhabit cellars, barns, and other dark places, and are of a brown or blackish colour. It is affirmed that the web of the field spider is inefficacious, while that collected in the cellars of houses, &c., has extraordinary medical virtues. Several authors speak in very decided terms of its powers as a febrifuge and antispasmodic. According to Dr. Robert Jackson, it is superior even to bark and arsenic in the cure of intermittents, and is, moreover, highly useful in various spasmodic and nervous diseases, controlling and tranquillizing irregular nervous action, exhilarating the spirits, and disposing to sleep, without producing any of the narcotic effects of opium on the brain. These praises are to a certain extent echoed by Dr. Chapman and Dr. Eberle, in their respective works on Therapeutics and Materia Medica. Among the complaints in which it has been found useful, besides intermittent fever, are periodical headach, the hectic fever of consumption, asthma, hysteria, and nervous irritations attended with morbid vigilance and irregular muscular action. It will be observed, that these are, for the most part, affections over which the imagination has much control. The dose of spider's web is five or six grains, to be given in the form of pill, and repeated every three or four hours. Dr. Jackson states that its influence is not in proportion to the quantity administered, and that he obtained the same effects from ten as from twenty grains. This might well be, if the supposition be allowed, that its chief operation is through the mind of the patient. Spider's web has also been used externally, with asserted advantage, as a styptic in wounds, and a healing application in superficial ulcers. Spiders themselves were formerly employed in the treatment of intermittent fever, and the application of the web to the cure of this disease is not a measure of recent origin.

COCOA. *Cacao. Chocolate Nuts.* These are the seeds of the *Theobroma Cacao*, a handsome tree, from twelve to twenty feet in height, growing in Mexico, the West Indies, and South America, in some parts of which it is largely cultivated, particularly in Guayaquil and Venezuela. The fruit is an oblong ovate capsule or berry, six or eight inches in length, with a thick, coriaceous, somewhat ligneous rind, enclosing a whitish pulp, in which numerous seeds are embedded. These are ovate, somewhat compressed, about as large as an almond, and consist of an exterior thin shell, and a brown oily kernel. Separated from the matter in which they are enveloped, they constitute the *cocoa* of commerce. They have a slightly aromatic, bitterish, oily taste, and, when bruised or heated, an agreeable odour. They contain a large quantity of fixed oil, together with albumen and bitter extractive. The oil is obtained by hot expression, or by decoction. It is a soft solid, whitish or yellowish, with a peculiar agreeable odour and a bland pleasant taste, and is known by the name of *cocoa butter.* It is said to be frequently adulterated with animal fats. The chief use to which it is applied, is as an ingredient in cosmetic unguents. The shells of the nuts are sometimes employed in the state of infusion, as a substitute for tea or coffee. They impart to boiling water a taste analogous to that of chocolate, but weaker. The kernel is consumed in great quantities, in the shape of chocolate, or in some analogous form.

Chocolate is differently prepared in different countries. In Great Britain and the United States, it usually consists, when pure, exclusively of the cocoa nuts, which are first roasted, then deprived of their shell, and lastly reduced, by grinding between heated stones, to the state of a paste, which is moulded into oblong cakes. Not unfrequently rice flour or other farinaceous substance, with butter or lard, is added; but these must be considered as adulterations. On the continent of Europe, sugar is generally incorporated with the paste, and spices, especially cinnamon, are often added. Vanilla is a favorite addition in South America, France, and Spain. Cocoa is often sold in the state of powder, which is sometimes mingled with other ingredients, such as ground rice, barley flour, sugar, &c. Chocolate is prepared for use by reducing it to powder, and boiling it in milk, water, or a mixture of these fluids. In this state it is much employed as a drink at the morning and evening meals, and serves as an excellent substitute for coffee in dyspeptic cases, being nutritive and digestible, without exercising any narcotic or otherwise injurious influence. It is also a good article of diet for convalescents, and may sometimes be given advantageously as a mild nutritive drink in cases of disease, though, under these circumstances, it should usually be prepared without milk, and of less strength than as ordinarily used.

CODFISH OIL. *Oleum Jecoris Aselli. Huile de Morue, Fr.* A fixed oil obtained from the liver of the codfish, the *Gadus Morrhua* of naturalists. It is procured by exposing the livers, heaped up in tubs, to the sun's rays. The oil flows out spontaneously, and is collected in proper vessels. That first received is limpid and of a light yellowish colour, and is reserved for internal use. After the commencement of putrefaction in the livers, a darker coloured oil flows out, which is unfit for medical purposes. A still darker and more offensive liquid is obtained by boiling the livers in iron pots.

Codfish oil has been much lauded, on the continent of Europe, particularly in Germany and Switzerland, as a remedy in gouty and rheumatic affections, scrofula and rickets, obstinate constipation, incontinence of urine, and intestinal worms. The dose is a tablespoonful three or four times a day for adults, a teaspoonful repeated as frequently for children. It may be taken alone, or mixed with some mucilaginous liquid. It is sometimes also applied externally by friction, and, in cases of ascarides or lumbricoides, is injected into the rectum.

COFFEE. The coffee plant—*Coffea Arabica*—belongs tot he class and order Pentandria Monogynia of the sexual system, and to the natural order Cinchonaceæ of Lindley. It is a small tree, rising from fifteen to twenty feet in height, and in favourable situations sometimes even thirty feet. The branches are opposite,the lower spreading, the upper somewhat declining, and gradually diminishing in length as they ascend, so as to form a pyramidal summit, which is covered with green foliage throughout the year. The leaves are opposite, upon short footstalks, oblong-ovate, acuminate, entire, wavy, four or five inches long, smooth and shining, of a dark green colour on their upper surface, paler beneath, and accompanied with a pair of small, pointed stipules. The flowers are white, with an odour not unlike that of the jasmine, and stand in groups in the axils of the upper leaves. The calyx is very small, the corolla salverform, with a nearly cylindrical tube, and a flat border divided into five lanceolate, pointed segments. The stamens project above the tube. The fruit, which is inferior, is a roundish berry, umbilicate at top, at first green, then red, and ultimately of a dark purple colour. It is about as large as a cherry, and contains two seeds, surrounded by a paper-like membrane, and enclosed in a yellowish pulpy matter. These seeds, divested of their coverings, constitute coffee.

The tree is a native of Southern Arabia and Abyssinia, and probably pervades Africa about the same parallel of latitude, as it is found growing wild at Liberia on the western coast of the continent. The value of its produce has led to its extensive cultivation in various parts of the world where the temperature is sufficiently elevated and uniform. Considerable attention has long been paid to its culture in its native country, particularly in Yemen, in the vicinity of Mocha, from which the demands of commerce were at first almost exclusively supplied. About the year 1690, it was introduced by the Dutch into Java, and in 1718 into their colony of Surinam. Soon after this latter period, the French succeeded in introducing it into their West India islands, Cayenne, and the Isles of France and Bourbon; and it has subsequently made its way into the other West India islands, various parts of tropical America, the peninsula of Hindostan, and Ceylon.

The tree is raised from the seeds, which are sown in a soil properly prepared, and germinating in less than a month, produce plants which at the end of the year are large enough to be transplanted. These are then set out in rows at suitable distances, and in three or four years begin to bear fruit. It is customary to top the trees at this age, in order to prevent their attaining an inconvenient height, and to increase the number of fruit-bearing branches. It is said that they continue productive for thirty or forty years. Though almost always covered with flowers and fruit, they yield most abundantly at two seasons, and thus afford two harvests during the year. Various methods are employed for freeing the seeds from their external coverings; but that considered the best, is by means of machinery to remove the fleshy portion of the fruit, leaving the seeds surrounded only by their papyraceous envelope, from which they are afterwards separated by drying and by the action of peeling and winnowing mills.

The character of coffee varies considerably with the climate and mode of culture. Consequently several varieties exist in commerce, named usually from the sources from which they are derived. The *Mocha coffee*, which is in small and roundish grains, takes the precedence of all others; but very little of it is now imported into Europe or America. The *Java coffee* is generally esteemed most highly in this country, and commands the highest price; but our chief supplies are derived from the West Indies and South America. Some good coffee, we are told, has recently been brought from Liberia. Coffee is thought to improve by age, losing a portion of its strength, and thus acquiring a more agreeable flavour. It is said to be much better when allowed to become perfectly ripe upon the tree, than as ordinarily collected. The grains should be hard, and so heavy as readily to sink in water. When soft, light, black or dark coloured, or musty, they are inferior.

The general aspect of coffee is too well known to need description. It has a faint peculiar odour, and a slightly sweetish, somewhat austere taste, entirely different from that developed by roasting. From the experiments of Seguin, Schrader, Robiquet and Pelletier, and other chemists, it appears to contain a minute quantity of volatile oil, a concrete fixed oil, gum, resin, an extractive matter having the characteristic taste of the coffee and affording a dark green precipitate with the salts of iron, albumen, a little sugar, saline substances, lignin, and a peculiar crystallizable principle which has received the name of *caffein*. This was first discovered by Runge, and afterwards by Robiquet. It may be obtained in the following manner. Exhaust bruised coffee by two successive portions of boiling water, unite the infusions, add acetate of lead in order to precipitate the principles which accompany the caffein, filter, decompose the excess of acetate of lead in the filtered liquor by sulphuretted hydrogen, and evaporate to the point of crystallization. The crystals which form may be purified by again dissolving them in water and evaporating. This is the process employed by Runge. (*Berzelius, Trait. de Chim.*) Pelletier obtained caffein by submitting the alcoholic extract of coffee to the action of water, treating the solution thus obtained with magnesia, filtering, evaporating the filtered liquor to the consistence of syrup, treating the residue with alcohol, and filtering and evaporating the alcoholic solution. (*Dict. des Drogues.*) Caffein crystallizes by the cooling of its concentrated solution, in opaque, silky, flexible needles; by slow and spontaneous evaporation, in long, transparent prisms. It has a feebly bitter and disagreeable taste, is soluble in water and alcohol, but insoluble in ether and oil of turpentine, combines neither with alkalies nor acids, melts when exposed to heat, and at a higher temperature sublimes, without residue, into needles analogous to those formed by benzoic acid. It is remarkable for containing a larger proportion of nitrogen than any other proximate vegetable principle, and in this respect equals some of the most highly animalized products. According to Pelletier and Caventou, its constituents are in 100 parts, 46.51 parts of carbon, 4.81 of hydrogen, 21.54 *of nitrogen*, and 27.14 of oxygen. Fibrin contains only about 20 per cent. of nitrogen. Notwithstanding the quantity of nitrogen in its composition, caffein does not putrefy, even when its solution is kept for some time in a warm place. Quite recently Pfaff has ascertained, what had been previously to a certain extent observed by Runge, that in the precipitate produced by acetate of lead with the decoction of coffee, there are two peculiar principles, one resembling tannin, the other having acid properties, and called *caffeic acid*. The latter may be obtained by decomposing with sulphuretted hydrogen the precipitate previously suspended in water, filtering the liquor, evaporating it to the consistence of syrup, and then adding alcohol, which precipitates the acid, mixed with several caffeates, from which the acid may be separated by boiling water. The most interesting character of this acid is that, when decomposed by heat, it exhales the odour of burnt coffee, and is therefore probably, in part at least, the source of those empyreumatic products, to the delicious flavour of which coffee owes its chief value.

Coffee undergoes considerable change during the roasting process. It swells up very much, acquiring almost double its original volume, while it loses about 20 per cent. of its weight. It acquires, at the same time, a peculiar odour entirely different from that of the unaltered grains, and a decidedly bitter taste. A volatile oil is developed during the process, and, according to Chenevix, a portion of tannin. The *caffein* does not appear to undergo material change, as, according to Garot, it may be extracted unaltered from the roasted coffee. The excellence of the flavour of roasted coffee depends much upon the manner in which the process is conducted, and the extent to which it is carried. It should be performed in a covered vessel, over a moderate fire, and the grains should be kept in constant motion. When these have acquired a chestnut-brown colour, the process should cease. If too long continued, it renders the coffee unpleasantly bitter and acrid, or by reducing it to charcoal, deprives it entirely of flavour. The coffee should not be burnt long before it is used, and should never be kept in the ground state, as it loses much of its agreeable flavour and activity.

Medical and Economical Uses. More attention has been paid to the effects of coffee on the system in the roasted than in the crude state. Unroasted coffee has been employed by Dr. Grindel of Russia in intermittent fevers, and the practice has been followed by some other physicians; but the success, though considerable, was not such as to lead to the conclusion that this medicine would answer as a substitute for Peruvian bark. It was given in powder in the dose of a scruple every hour, or in decoction prepared by boiling an ounce with eighteen ounces of water down to six, or in the state of extract in the dose of from four to eight grains. Whether its operation corresponds with that of the roasted coffee we are unable to say. The following observations relate only to the latter.

The action of coffee is directed chiefly to the nervous system. When swallowed it produces a warming cordial impression on the stomach, quickly followed by a diffused agreeable nervous excitement, which extends itself to the cerebral functions, giving rise to increased vigour of imagination and intellect, without any subsequent confusion or stupor such as characterizes the action of narcotic medicines. Indeed one of its most extraordinary effects is a disposition to wakefulness, which continues for several hours after it has been taken. It is even capable of resisting, to a certain extent, the intoxicating and soporific influence of alcohol and opium, and may sometimes be advantageously employed for this purpose. It also moderately excites the circulatory system, and stimulates the digestive function. A cup of coffee taken after a hearty meal, will often relieve the sense of oppression so apt to be experienced, and enable the stomach to perform its office with comparative facility. These exhilarating effects of coffee, united with its delicious flavour when suitably qualified by cream and sugar, have given rise to its habitual employment as an article of diet. Its use for this purpose has prevailed from time immemorial in Persia and Arabia. In 1517 it was introduced by the Turks into Constantinople, whence it was carried to France and England about the middle of the succeeding century, and has since gradually made its way into almost universal use. It cannot be supposed that a substance capable of acting so energetically upon the system, should be entirely destitute of deleterious properties. Accordingly, if taken in very large quantities, it leaves, after its first effects are passed, a degree of nervous derangement or depression equivalent to the previous excitement; and its habitual immoderate employment is well known very greatly to injure the tone of the stomach, and frequently to give rise to troublesome dyspeptic affections. This result is peculiarly apt to take place in individuals of naturally susceptible nervous systems, and in those of sedentary habits.

In the treatment of disease, coffee has been less employed than might have been expected from its effects upon the system. There can be no doubt that it may be advantageously used in various nervous affections. In a tendency to stupor or lethargy dependent on deficient energy of the brain, without congestion or inflammation, it would be found useful by stimulating the cerebral functions. In light nervous headachs, and even in sick headach not caused by the presence of offending matter in the stomach, it often proves useful. It has acquired much reputation as a palliative in the paroxysm of spasmodic asthma, and is recommended by some writers in hysterical affections. The Egyptians are said to have formerly employed it as a remedy in amenorrhœa. Hayne informs us that in a case of violent spasmodic disease, attended with short breath, palpitation of the heart, and a pulse so much increased in frequency that it could scarcely be counted, immediate relief was obtained from a cup of coffee, after the most powerful antispasmodics had been used in vain for several hours. It is said also to have been used very effectually in obstinate chronic diarrhœa; and Dr. Chapman of Philadelphia has found it highly useful in calculous nephritis. In all inflammatory affections of a high grade it is contraindicated.

Coffee is usually prepared in this country by boiling the roasted grains, previously ground into a coarse powder, in water for a short time, and then clarifying by the white of an egg. Some prefer the infusion, which has more of the aroma of the coffee, with less of its bitterness. The proper proportion for forming the infusion for medical use, is an ounce to a pint of boiling water, of which a cupful may be given warm for a dose, and repeated if necessary.

COLLINSONIA CANADENSIS. *Horse-weed. Horse-balm. Richweed. Heal-all. Stone-root. Knot-root.* An indigenous plant, with a perennial, knotty root, and an herbaceous simple stem about two feet high, furnished with two or three pairs of broad, cordate ovate, smooth leaves, and terminating in a panicle of yellow flowers in branched racemes. The flowers are diandrous and monogynous, with a labiate calyx and corolla, the latter of which has the lower lip fringed. The plant grows in woods from Canada to Carolina, and flowers from July to September. The whole plant has a strong disagreeable odour, and a warm pungent taste. It is considered tonic, astringent, diaphoretic, and diuretic; and the root in substance is said to irritate the stomach and produce vomiting even in small doses. The plant is used in numerous complaints in domestic practice. It is preferred in the fresh state, as the active principle is volatile. A decoction of the fresh root is said to have been used with advantage in catarrh of the bladder, leucorrhœa, gravel, dropsy, and other complaints; and the leaves are applied by the country people, in the form of cataplasm or fomentation, to wounds, bruises, and sores, and in cases of internal abdominal pains.

COLUTEA ARBORESCENS. *Bladder Senna.* A shrub, growing spontaneously in the southern and eastern parts of Europe, and cultivated in gardens as an ornamental plant. Its leaves are pinnate, consisting of from three to five pairs of leaflets, with an odd one at the end. The leaflets are obovate, slightly emarginate, smooth and of a deep green colour on the upper surface, grayish-green and somewhat pubescent beneath. The flowers are yellow, and the fruit vesicular, whence the plant derived its vulgar name. The leaflets are possessed of purgative properties, and, in some parts of Europe, are used as a substitute for senna, which is said to be sometimes adulterated with them. The bladder senna is comparatively very feeble. It is administered in infusion or decoction, of which the dose is about half a pint, containing the virtues of from one to three ounces of the leaves.

COMPTONIA ASPLENIFOLIA, *Sweet Fern.* A shrubby indigenous plant, named from the resemblance of its leaves to the *spleenwort fern*, but belonging to the Linnæan class and order *Monœcia Triandra.* It grows in thin sandy or stony woods, from New England to Virginia. All parts of it possess a resinous spicy odour, which is increased when the plant is rubbed. It is said to be tonic and astringent, and to be occasionally used in domestic practice as a remedy in diarrhœa, and various other complaints. It is employed in the form of decoction.

CONVALLARIA MAJALIS. *Lily of the Valley.* This charming little garden flower is a native of Europe, and is found growing wild in the United States, upon the highest mountains of Virginia and Carolina. The *flowers* have a strong delightful odour, which is in great measure lost by drying. Their taste is nauseous, bitter, and acrid. Taken internally they are said to be emetic and cathartic, and their extract purges actively in the dose of half a drachm. They were formerly used in epilepsy and against worms. At present they are employed only as a sternutatory, for which purpose they are dried and reduced to a coarse powder. The *root*, which is also bitter, has similar purgative properties, and, reduced to powder, is said to be sternutatory.

CONVALLARIA POLYGONATUM, Linn. *Polygonatum uniflorum*, Desfontaines. *Solomon's seal.* A perennial, herbaceous European plant, the root of which is horizontal, jointed, white, and marked, at short intervals, with small circular impressions, which bear a remote resemblance to those made by a seal, and have served to give a name to the plant. The root is inodorous, and of a sweetish mucilaginous taste, followed by a slight degree of bitterness and acrimony. It is said to be emetic. In former times it was used externally in bruises, tumours, wounds, and cutaneous eruptions, and was highly esteemed as a cosmetic. At present it is not employed, though recommended by Hermann as a good remedy in gout and rheumatism. The berries and flowers are said to be acrid and poisonous.

The *C. multiflora* (*Polygonatum multiflorum*, Desf.), which grows in this country, as well as in Europe, is analogous to the preceding in properties.

COPAL. A resinous substance, brought from the East Indies, South America, and the western coast of Africa, but most abundantly from the first mentioned source. It is the concrete juice of different trees, and is furnished by exudation. The East India copal is said to be derived from the *Vateria Indica* of Linn., the *Elæocarpus copalliferus* of Retzius; and the Brazilian is attributed by Martius and Hayne, probably with justice, to different species of *Hymenæa.* Copal varies somewhat in appearance and properties, as procured from different sources. It is in roundish, irregular, or flattish pieces, colourless, yellowish, or brownish-yellow, more or less transparent, very hard, with a shining conchoidal fracture, inodorous and tasteless, of a sp. gr. varying fron 1.045 to 1.139, insoluble in alcohol, soluble in ether, and slightly so in oil of turpentine. Some varieties unite with alcohol if suspended in its vapour while boiling. By heat it melts and is partially decomposed, becoming thereby soluble in alcohol and oil of turpentine. It is not a proximate principle, but consists of various resins united in different proportions. The East India copal is in flatter pieces than the American or African, and is whiter, softer, and less transparent. Two kinds are known in the drug market—the *crude* and the *scraped*—the former of a dull opaque appearance externally, the latter much clearer and more transparent, in consequence of being deprived of its outer coat. The process of *scraping* is said to consist in the removal of the exterior portion by means of an alkaline solution, which readily dissolves copal. This resin is used chiefly in the preparation of varnishes.

CORAL. A substance found at the bottom of the Mediterranean and other Seas, supposed originally to belong to the precious stones, afterwards considered as a plant, but now universally admitted to belong to the animal kingdom. The *red coral* (*Corallium rubrum* of Lamarck, *Isis nobilis* of Linn.) is in the form of a small shrub, a foot or two in height, with a stem sometimes an inch in thickness, fixed to the rock by an expansion of the base, divided above into branches, and covered with a pulpy membrane, which is properly the living part, and which is removed when the coral is collected. The central portion is extremely hard, of various shades of red, susceptible of a brilliant polish, longitudinally striated, and formed of concentric layers, which are rendered obvious by calcination. Its chief constituent is carbonate of lime, which is coloured by oxide of iron, and united, as in similar calcareous products, with more or less animal matter. It was formerly very highly valued as a remedy in numerous diseases, but is in no respect superior to prepared oyster shells, or other form of carbonate of lime derived from the animal kingdom. It was employed in the form of fine powder, or in different preparations, such as troches, syrups, conserves, tinctures, &c. At present it is valued chiefly as an ornament.

CORTEX CARYOPHYLLATA. *Cassiaa Cryophyllata. Clove Bark.* These names have been given to a bark, brought from the West Indies, and derived from a tree belonging to the family of the Myrtaceæ, supposed to be the *Myrtus acris* of Schwartz. It is usually in cylinders from one to two feet long by an inch in diameter, composed of numerous separate pieces rolled around one another, having a dark brown colour, a pungent taste, and an odour similar to that of cloves. It is sometimes in fragments, of a similar colour, taste, and smell, but softer and lighter, and supposed to be derived from older branches. A similar bark is said to be derived from the *Myrtus caryophyllata* of Linn., which grows in Ceylon. The clove bark has aromatic properties not unlike those of the spice from which it derived its name; but it is much inferior, and is now never used in this country. Some authors have confounded with it a wholly different bark produced by a tree growing in the Moluccas, and known by the Indian name of *culilawan.* (See *Culilawan.*)

CREOSOTE. *Creosotum.* This is the name of a substance, of the nature of the volatile oils, which was discovered in 1830 by Dr. Reichenbach of Moravia in the products of the distillation of wood. In the products of the distillation of organic substances generally, whether vegetable or animal, he also discovered five other substances, called paraffine, eupione, picamar, capnomor, and pittacal. *Paraffine* is a white, crystalline, soft solid, devoid of taste or smell, and characterized by its feeble affinity for other bodies, as is indicated by its name, from *parum affinis.* *Eupione* is an inodorous, insipid, limpid, and colourless liquid, of the sp. gr. 0.740, obtained most abundantly from animal tar, and Dippel's animal oil. Both these substances are composed exclusively of hydrogen and carbon. *Picamar* is an oily colourless liquid, heavier than water, of a peculiar odour and very bitter taste. It is present in the heaviest portion of the rectified oil of tar, and constitutes the bitter principle of that substance. *Capnomor*, so called from its being one of the ingredients of smoke, is a colourless liquid, lighter than water, having a pleasant odour and a pungent taste, and occurring in the heavy oil of tar. It has the property of dissolving caoutchouc, and is an ingredient in coal naphtha, which derives from its presence the property of dissolving the same substance. *Pittacal*, also obtained from the heavy oil of tar, is a solid of a beautiful blue colour, and differing from the other substances above noticed, in containing nitrogen as one of its elements. These five substances have no uses, but creosote has attracted a large share of attention since its discovery, on account of its alleged therapeutic powers.

Preparation. Creosote is obtained either from tar or from crude pyroligneous acid. When tar is used, it is distilled until it has attained the consistence of pitch. The distilled liquid divides itself into three layers, an aqueous between two oily layers. The inferior oily layer, which alone contains the creosote, is separated, and saturated with carbonate of potassa, to remove acetic acid. The liquid is allowed to rest, and the new oil which separates is decanted from it. This oil is distilled, and yields products lighter than water, and a liquid heavier. The latter alone is preserved, and, having been agitated repeatedly with weak phosphoric acid to neutralize ammonia, is allowed to remain at rest for some time. It is next washed as long as acidity is removed, and then distilled with a fresh portion of weak phosphoric acid, observing to cohobate from time to time. The oily liquid thus rectified is colourless, and contains much creosote, but also a portion of eupione. To separate these the liquid is mixed with a solution of caustic potassa of the density of 1.12, which dissolves the creosote, but not the eupione. Having separated the eupione which swims above from its levity, the alkaline solution of the creosote is exposed to the air, until it becomes brown as a consequence of the destruction of a foreign matter, and is then saturated with sulphuric acid. This sets free the creosote, which is decanted and again distilled. The treatment by solution of potassa, sulphuric acid, &c., is to be repeated until the creosote no longer becomes brown by exposure to the air, but only slightly reddish. It is then dissolved in a stronger solution of potassa and distilled again, and finally re-distilled for the last time, rejecting the first portions which come over on account of containing much water, collecting the next portions, and avoiding to push the distillation too far. The product collected in this distillation is pure creosote.

When creosote is extracted from pyroligneous acid, the first step is to dissolve sulphate of soda in it to saturation. The oil which separates and swims above is decanted, and, having been allowed to remain at rest for a few days, is saturated by carbonate of potassa with the assistance of heat, and distilled with water. The oleaginous liquid obtained is of a pale yellow colour, and is to be treated with phosphoric acid, &c. &c., as above detailed with respect to the treatment of the corresponding oil obtained from tar.

Properties. Creosote is a colourless oleaginous liquid, of the consistence of oil of almonds, slightly greasy to the touch, and having a caustic and burning taste, and a penetrating, disagreeable odour, which recalls that of smoked meat. Applied to the skin in a concentrated state it quickly destroys the cuticle. On paper it leaves a greasy stain, which disappears in a few hours, or very rapidly when exposed to a gentle heat. Its sp. gr. is 1.037. It boils at 397°, retains its fluidity at—17°, is a non-conductor of electricity, and refracts light powerfully. It is devoid of acid or alkaline reaction. Mixed with water, it forms two combinations—one a solution of 1 part of creosote in 400 of water, the other, of 1 part of water in 10 of creosote. It unites in all proportions with alcohol, ether, and naphtha. It is capable of dissolving a large quantity of iodine and phosphorus, and a considerable portion of sulphur, especially when assisted by heat.

Creosote forms two combinations with potassa, one anhydrous, of an oleaginous consistence, the other, hydrated, and in the form of small, white pearly scales. It possesses similar habitudes with soda. It instantly dissolves ammonia, and retains it with great force. It dissolves the oxide of copper also, but is converted into a resinous matter by the oxide of mercury, which in the mean time is reduced. Nitric and sulphuric acids, in a concentrated state, decompose creosote, the former giving rise to abundant reddish vapours, the latter to a red colour, which becomes black on the addition of more of the acid. Acetic acid unites with it in all proportions without decomposing it. Creosote dissolves a large number of metallic salts, and reduces a few to the metallic state; as for example, nitrate and acetate of silver. It possesses the power of coagulating albumen.

Of all the properties of creosote, the most important is its power of preserving meat. It is this property which has suggested its name, derived from *κρεὰς flesh*, and *σωζω I save.* Dr. Reichenbach states that fresh meat, dipped for a quarter of an hour in a solution of creosote, is preserved from putrefaction, and concludes that smoked meats owe their power to resist change to the presence of this substance.

Medical Properties, &c. Creosote in its pure state is a moderate escharotic; when in solution, a stimulant and antiseptic. It is used both internally and externally. Internally it has been employed in a number of diseases; externally, for the most part as an application to eruptions, wounds, and ulcers, and as an injection and gargle. The principal diseases in which it has been given are catarrh, hemoptysis, and pulmonary consumption. Over the latter disease it has no curative influence; but it is stated to facilitate expectoration and to give the sputa a more favourable character. The eruptions to the treatment of which it has been supposed to be best suited are itch, and the various kinds of tetters. In burns its efficacy has been fully established, especially in those attended with excessive suppuration and fungous granulations. In chilblaines also it is stated to be a useful application. When applied to wounds, it has a decided effect in stopping the capillary hemorrhage, but no power to arrest the bleeding from large vessels, as has been erroneously asserted. The ulcers, in the treatment of which it has been found most useful, are those of an indolent and gangrenous character, in which its several properties, escharotic, stimulant, and antiseptic, are usefully brought into play. It is also praised as an application to syphilitic, scrofulous, and cancerous ulcers. In all these cases, the remedy must be used of appropriate strength, and continued with judgment; and in case it should irritate, its use should be suspended, or alternated with that of emollient and soothing applications. In fistulous ulcers, it proves a useful resource, used by injection, by exciting the callous surfaces and disposing them to unite. In cases of putrid sorethroat, in which the use of a stimulant and antiseptic are required, a gargle of creosote acts beneficially; and in chronic suppuration of the external meatus of the ear, the same properties make it valuable as an injection. A drop or two inserted in the hollow of a carious tooth will destroy the exposed surface of the nerve, and in many instances temporarily cure the toothach.

Creosote is employed in a pure state, in mixture or solution, and in the form of ointment. In the pure state, it may be brushed over indolent or ill-conditioned ulcers, or applied by means of lint, to arouse their sensibility, or to create a new action. Internally it is given in mixture, in the dose of one or two drops, or more, repeated several times a day, in a fluidounce of the vehicle. When used as a lotion for eruptions, ulcers, or burns, or as a gargle or injection, it is employed in solution, containing two, four, or six drops to the fluidounce of distilled water, the strength being determined by the circumstances of each particular case. The ointment of creosote is made of various strengths according to the object in view. When used in frictions to tumors or indurations, six or eight drops may be mixed with an ounce of lard; and when applied as a dressing to ulcers or eruptions, a drachm may be rubbed up with the same quantity of lard. In some cases the solution of creosote is used externally, mixed with poultices.

No antidote is known to the poisonous effects of creosote; but its presence is easily detected after death by its peculiar and penetrating smell.

According to Ettling, creosote consists of 7.8 hydrogen, 76.2 carbon, and 16 oxygen, proportions which coincide most nearly with nine equiv. of hydrogen, fourteen of carbon, and two of oxygen.

CUCURBITA CITRULLUS. *Watermelon.* The seeds of the watermelon are employed to a considerable extent as a domestic remedy in strangury and other affections of the urinary passages. They have the same properties with the seeds of the other Cucurbitaceæ, of which four different kinds were formerly officinal under the name of the *greater cold seeds*—viz. those of the *Cucurbita Pepo* or pumpkin, the *Cucurbita Lagenaria* or gourd, the *Cucumis Melo* or muskmelon, and the *Cucumis sativus* or cucumber. These, when bruised and rubbed up with water, form an emulsion which was formerly thought to possess considerable virtues, and was much used in catarrhal affections, disorders of the bowels and urinary passages, fever, &c. Of late, however, they have been entirely neglected, having been superseded by other more agreeable demulcents. The watermelon seeds are esteemed by some diuretic, as well as demulcent. They are usually given in the form of infusion, made in the proportion of one or two ounces of the bruised seeds to a pint of water, and taken *ad libitum.*

CULILAWAN. *Cortex Culilaban.* An aromatic bark, produced by the *Laurus Culilaban*, a tree of considerable size, growing in the Molucca islands, Cochinchina, and other parts of the East. It is usually in flat or slightly rolled pieces, several inches long, an inch or more in breadth, and one or two lines thick. Sometimes the bark is thinner and more quilled, bearing considerable resemblance to cinnamon. The epidermis is for the most part removed, but when present is of a light brownish-gray colour, soft to the touch, and somewhat spongy. The colour of the bark itself is a dull dark cinnamon-brown, the odour highly fragrant, the taste agreeably aromatic, and not unlike that of cloves. The active constituent is a volatile oil which may be separated by distillation. Culilawan has the medical properties common to the aromatics, but is scarcely used at present.

CUNILA MARIANA. *American Dittany.* A small indigenous perennial herb, growing on dry, shady hills, from New England to Georgia, and flowering in June and July. The whole herb has a warm pungent taste, and a fragrant odour, dependent on an essential oil which may be obtained separate by distillation with water. The medical properties of the plant are those of a gently stimulant aromatic, analogous to the mints, pennyroyal, &c. In the shape of warm infusion, it is popularly employed to excite perspiration in colds and slight fevers, to promote suppressed menstruation, to relieve flatulent colic, and for various other purposes to which the aromatic herbs are thought applicable.

CUTTLE-FISH BONE. *Os Sepiæ.* This is a calcareous body, situated underneath the skin, in the back of the *Sepia officinalis*, or *cuttle-fish*, which inhabits the seas of Europe, especially in the Mediterranean, in the waters of which the bone is not unfrequently found floating. It is oblong-oval, from five to ten inches long, and from one and a half to three inches broad, somewhat convex on both sides, with thin edges, of a rather firm consistence upon the upper surface, very friable beneath, and composed of numerous layers, loosely connected, so as to give to the mass a porous consistence. It is lighter than water, of a white colour, a feeble odour of sea-plants, and a saline taste. It contains, according to John, from 80 to 85 per cent. of carbonate of lime, besides animal matter, a little common salt, and traces of magnesia. Reduced by levigation and elutriation to a fine powder, it may be given as an antacid under similar circumstances with chalk or oyster-shell. It is sometimes used as an ingredient of tooth-powders. Small pieces of it are often put into bird cages, that the birds may rub their bills against them; and the powder is employed for polishing.

Another product of the cuttle-fish is a blackish-brown liquor, secreted by a small gland into an oval pouch, communicating externally near the rectum by a long excretory duct, through which the animal is said to have the power of ejecting it at will. This, when taken from the fish, is dried, and used in the preparation of the water colour called *sepia.*

CYANURET OF POTASSIUM. This medicine, from its growing importance, deserves a more extended notice than that given to it under the head of hydrocyanic acid, in the note at page 713. It is obtained from the yellow salt, called ferrocyanate of potassa, which is in fact a double cyanuret of potassium and iron. The double salt is first dried, and then exposed, in a porcelain or stoneware retort, to a long continued red heat, until nitrogen ceases to be disengaged. During the cooling of the retort, its mouth is closed by luting, to prevent the access of air. By the calcination, the cyanuret of iron is decomposed and converted into quadricarburet of iron, while the cyanuret of potassium remains unchanged. The calcined product is a blackish lamellar mass, consisting of the cyanuret of potassium, rendered impure by the charcoal and iron derived from the decomposed cyanuret. It is purified by treating it with a small quantity of cold water, which dissolves the cyanuret of potassium, leaving the impurities behind. The solution is then evaporated to dryness under an exhausted receiver, by means of sulphuric acid, and the dry mass is the cyanuret in question.

Cyanuret of potassium is usually yellow, but perfectly white and transparent when very pure. Its taste is alkaline. In close vessels, it is indecomposable by heat; but it is readily decomposed by the action of water, especially at the boiling point, being converted into ammonia and formiate of potassa. Even moisture is sufficient to determine its decomposition in part. It is very soluble in water, but sparingly so in alcohol. All acids have the power of decomposing it, not excepting the carbonic. It is on this account that its solution constantly emits the smell of hydrocyanic acid by contact of air, and is converted into carbonate of potassa. It consists of one equiv. of cyanogen and one of potassium.

Medical Properties, &c. This cyanuret is pre-eminently poisonous, acting precisely like hydrocyanic acid. The tenth of a grain of the salt killed a small bird in the space of a minute. A solution of five grains destroyed a large dog in a quarter of an hour. As a medicine it is considered applicable to all cases in which hydrocyanic acid has been found useful. The grounds on which it has been proposed as a substitute for that acid are its uniformity as a chemical product, and its less liability to undergo decomposition. The dose is a quarter of a grain, gradually increased to a grain. The solution, *extemporaneously* made, is the most convenient form for exhibition; and a standard solution has been proposed by Magendie, under the name of medicinal hydrocyanate of potassa, prepared by dissolving the cyanuret in eight times its weight of distilled water. A solution of this strength is equivalent to the medicinal hydrocyanic acid, and may be prescribed in mixtures in the dose of two or three drops.

CYANURET OF ZINC. This cyanuret is precipitated as a white insoluble powder, by adding cautiously, until it ceases to produce a precipitate, a recent, filtered solution of cyanuret of potassium, obtained from the impure black cyanuret, to a solution of sulphate of zinc. It is used in Germany as a substitute for hydrocyanic acid, and is said to possess anthelmintic properties. It has been employed with alleged advantage in cramp of the stomach and in the colics attendant on difficult menstruation. The dose is a quarter of a grain, gradually increased to a grain and a half, given in mixture.

CYNANCHUM VINCETOXICUM. R. Brown. *Asclepias Vincetoxicum.* Linn. *White Swallow-wort. Vincetoxicum.* A perennial herbaceous European plant, the root of which was formerly esteemed a counterpoison, and hence gave origin to the officinal name. It has a bitterish acrid taste, and when fresh, a disagreeable odour which is diminished by drying. Taken internally, especially in the recent state, it excites vomiting, and is capable in large quantities of producing dangerous if not fatal inflammation of the stomach. Its former reputation as an alexipharmic was wholly without foundation. It is said to be useful in cutaneous diseases, scrofula, &c.; but is little employed. The leaves of the plant also are emetic. Feneulle found in the root a peculiar principle analogous to emetin.

CYNOGLOSSUM OFFICINALE. *Hound's Tongue.* A biennial plant, common both in Europe and this country, and named from the shape of its leaves. The leaves and root have been employed, but the latter has been generally preferred. The fresh plant has a disagreeable narcotic odour resembling that of mice, which is dissipated by drying. The taste is nauseous, bitterish, and mucilaginous. Different opinions as to its powers have been entertained, some considering it as nearly inert, others as a dangerous poison; nor has the difference been hitherto settled. Hound's tongue has been used as a demulcent and sedative in coughs, catarrh, spitting of blood, dysentery, and diarrhœa: and has been applied externally in burns, ulcers, scrofulous tumours, and goitre. The *pilulæ de cynoglosso*, which are officinal in some parts of Europe, though they contain a portion of the root of hound's tongue, owe their properties chiefly to opium.

DICTAMUS ALBUS. *White Fraxinella. Bastard Dittany.* This is a perennial European plant, the root of which is bitter and aromatic, and has been used as an anthelmintic, emmenagogue, and stomachic tonic, though at present little employed in Europe, and not at all in this country. Störck gave it in intermittents, worms, amenorrhœa, hysteria, epilepsy, and other nervous diseases. The bark of the root is the most active part. The dose in powder is from twenty grains to a drachm or more.

DIPPEL'S ANIMAL OIL. *Oleum Cornu Cervi.* This oil is obtained during the distillation of animal matters, in the processes for obtaining the ammoniacal products on a large scale. That portion which first comes over is pale yellow; but, in the progress of the distillation, it becomes gradually deeper coloured and thicker, and at last black and viscid. It is purified and rendered colourless by redistillation, a pyrogenous resin being left behind. Thus rectified it is a colourless liquid, very limpid and volatile, and having a penetrating, extremely fetid odour, and burning taste. It is soon altered by the action of air and light, becoming thick, yellow, brown, and finally black. It possesses an alkaline reaction, and is alleged by Unverdorben to contain four oily salifiable bases, to which he has given names; but these are of doubtful existence.

This oil was formerly much used in medicine, but its repulsive odour and taste have caused it to be almost entirely laid aside. It acts, in the dose of a few drops, given with water, as a stimulant and antispasmodic. Its presence in the spirit and salt of hartshorn gives to these preparations medicinal properties different from those of the pure carbonate of ammonia.

DIRCA PALUSTRIS. *Leather Wood.* An indigenous shrub, usually very small, but sometimes attaining the height of five or six feet, growing in boggy woods, and other low wet places, in almost all parts of the United States, though less abundantly in the western than in the eastern section. The berries, which are small, oval, and of an orange colour, are said to be narcotic and poisonous. The bark is the part which has attracted most attention. It is extremely tough, and of very difficult pulverization. In the fresh state it has a peculiar rather nauseous odour, and an unpleasant acrid taste, and when chewed excites a flow of saliva. It yields its acrimony completely to alcohol, but imperfectly to water even by decoction. In the dose of six or eight grains, the fresh bark produces violent vomiting, preceded by a sense of heat in the stomach, and often followed by purging. Applied to the skin it excites redness, and ultimately vesicates; but its epispastic operation is very slow. It appears to be analogous in its properties to mezereon, to which it is also botanically allied, as the two barks are derived from plants belonging to the same natural order.

DRAGON'S BLOOD. *Sanguis Draconis.* This is a resinous substance obtained from the fruit of several species of *Calamus*, especially the *C. Rotang* and *C. Draco*, small palms, growing in the Molucca Islands and other parts of the East Indies. On the surface of the fruit, when ripe, is an exudation, which is separated by rubbing, or shaking in a bag, or by exposure to the vapour of boiling water, or finally by decoction. The finest resin is procured by the two former methods. It comes in two forms; sometimes in small *oval masses*, of a size varying from that of a hazelnut to that of a walnut, covered with the leaves of the plant, and connected together in a row like beads in a necklace; sometimes in *cylindrical sticks* eighteen inches long and from a quarter to half an inch in diameter, thickly covered with palm leaves, and bound round with slender strips of cane. In both these forms, it is of a dark reddish-brown colour, opaque, and readily pulverizable, affording a fine scarlet powder. An inferior kind, said to be obtained by boiling the fruit in water, comes in *flat circular cakes*, two or three inches in diameter and half an inch thick. This also yields a fine red powder. A fourth variety, much inferior even to the last mentioned, is in *large disks*, from six to twelve inches in diameter by an inch in thickness, mixed with various impurities, as pieces of the shell, stem, &c., and supposed to be derived from the fruit by decoction with expression. A substance known by the name of Dragon's blood is also derived by exudation from the trunk of the *Dracæna Draco*, a large tree inhabiting the Canary Islands, and another from the *Pterocarpus Draco*, a tree of the West Indies and South America, by incision into the bark. These last, however, are little known in commerce.

Dragon's blood is inodorous and tasteless, insoluble in water, but soluble in alcohol, ether, and the volatile and fixed oils, with which it forms red solutions. According to

Herberger, it consists of 90.7 parts of a red resin which he calls *draconin*, 2.0 of fixed oil, 3.0 of benzoic acid, 1.6 of oxalate of lime, and 3.7 of phosphate of lime. It was formerly used in medicine as an astringent, but is nearly or quite inert, and is now never given internally. It is sometimes used to impart colour to plasters, but is valued chiefly as an ingredient of paints and varnishes.

DUTCH PINK. A yellow or brownish-yellow paint, consisting of clay, or a mixture of clay and chalk, or carbonate of lime in the form of whiting, coloured by a decoction of woad, French berries, or birch leaves, with alum.

EMERY. A very hard mineral, the powder of which is capable of wearing down all other substances except the diamond. As found in commerce, it is said to be derived chiefly from the island of Naxos in the Grecian Archipelago. It is pulverized by grinding it in a steel mill; and the powder is kept in the shops of different degrees of fineness. It is used for polishing metals and hard stones.

EUPHRASIA OFFICINALIS. *Eyebright.* A small annual plant, common to Europe and the United States, without odour, and of a bitterish, astringent taste. It was formerly used in various complaints, and among the rest in disorders of the eyes, in which it was thought to be very efficacious, and in the treatment of which it is still popular in some countries. Its ordinary name arose from its supposed efficacy in improving vision. The probability is that it is nearly inert.

FERROCYANATE OF POTASSA. This is the yellow double cyanuret of potassium and iron, the salt from which the cyanuret of potassium is obtained by calcination. It is prepared on the large scale by calcining animal matters, such as dried blood, horns, &c., with the pearlash of commerce, dissolving the calcined mass after cooling in water, mixing the solution with one of sulphate of iron, until Prussian blue begins to be formed, decanting the liquid, and evaporating it so as first to crystallize the sulphate of potassa, and afterwards the double cyanuret. This salt is in large, transparent, four-sided, tabular crystals, of a lemon-yellow colour, devoid of odour, but possessing a slightly bitter taste. It dissolves in between three and four times its weight of cold water, and in about its own weight at the boiling temperature. When heated to 140° it loses its water of crystallization, amounting to three equivalents and becomes white. It consists, exclusive of water, of two equiv. of cyanuret of potassium, and one of cyanuret of iron.

Medical Properties, &c. The physiological action of this salt has not been well studied. It is asserted by Dr. Wöhler to pass readily into the urine. The only notice we have seen of its use as a medicine is contained in a paper by Dr. Burleigh Smart, of Kennebec, Maine, published in February, 1835. (*Amer. Journ. of Med. Sci.* xv. 362.) According to this writer, its primary effect is that of a sedative, lessening the fulness and frequency of the pulse, and diminishing pain and irritation. It also acts, under favourable circumstances, as a diaphoretic and astringent. Dr. Smart used it with success in a case of chronic bronchitis in a child, with the effect, in a few days, of diminishing the frequency of the pulse, and of lessening the sweating, cough, and dispnœa. It sometimes acts as a diaphoretic, but only in cases attended with excessive vascular action and increased heat of skin. As an astringent, its power is most conspicuous in the colliquative sweats of chronic bronchitis and phthisis. The same power was evinced in several cases of leucorrhœa cured by its use. It sometimes produces ptyalism, unattended, however, by swelling of the salivary glands or fetor of the breath. Its properties as an anodyne and sedative render it applicable to cases of neuralgic pains and whooping cough, in which diseases, especially the latter, Dr. Smart found it useful. When given in an over-dose it occasions vertigo, coldness, and numbness, with a sense of gastric sinking.

For administering this remedy, Dr. Smart prefers the form of solution, in the proportion of two drachms to the fluidounce of water. Of this solution the dose for an adult is from 30 to 45 drops, equivalent to from 10 to 15 grains, repeated every four or six hours. Should the results of Dr. Smart be confirmed by the profession, the ferrocyanate of potassa will form an important acquisition to the Materia Medica.

FRENCH CHALK. A variety of indurated talc. It is compact, unctuous to the touch, of a greenish colour, glossy, somewhat translucent, soft and easily scratched, and leaves a silvery line when drawn over paper. It is used chiefly for marking cloth, &c., and for extracting grease spots.

FUMARIA OFFICINALIS. *Fumitory.* A small annual European plant, naturalized in this country, growing in cultivated grounds, and flowering from May to August. It was formerly considerably improved as a medicine, and is still used in Europe. The leaves are the officinal part. They are inodorous, have a bitter saline taste, and are very succulent, yielding by expression a juice which has the sensible and medicinal properties of the plant. An extract prepared by evaporating the expressed juice, or a decoction of the leaves, throws out upon its surface a copious saline efflorescence. The plant, indeed, abounds in saline substances, and to these in connexion with its bitter extractive, are to be ascribed any medical virtues which it may possess. It is gently tonic, in large doses is said to be laxative and diuretic, and is thought, moreover, to exercise an alterative influence over the system. Both in ancient and modern times it has been esteemed a valuable remedy in visceral obstructions, particularly those of the liver, in scorbutic affections, and in various troublesome eruptive diseases of the skin. Cullen speaks very favourably of its influence in these last complaints. He gave the expressed juice in the dose of two ounces twice a day. Others have prescribed it in much larger quantities. The leaves either fresh or dried may be used in decoction, without precise limitation as regards the dose. The inspissated juice and an extract of the dried leaves have also been employed, and are said to have all the virtues of the leaves themselves.

FUSTIC. A yellow dye-wood, obtained from the *Morus tinctoria* (*Broussonetia tinctoria*, Kunth), a tree growing in the West Indies and South America. It is not used in medicine or pharmacy. According to Bancroft, two different woods bear in England the name of fustic, one the product of the tree just mentioned, distinguished as *old fustic*, probably from the greater magnitude of the billets in which it is imported; the other derived from the *Rhus Cotinus* or *Venice sumach*, and called *young fustic*.

GALANGAL. *Galanga.* Two varieties of this drug are described by authors, the *galanga major* or *large galangal*, and the *galanga minor* or *small galangal*. They are considered by some as the roots of two distinct plants; but there is reason to believe that they are both derived from the *Maranta Galanga* of Linn., the *Alpinia Galanga* of Willd., and that they differ in consequence of the different stages of growth at which they are collected. They are brought from the East Indies. The *larger variety* is cylindrical, three or four inches long, as thick as the thumb or thicker, often forked, reddish-brown externally, slightly striated longitudinally, marked with whitish circular rings, yellowish-reddish-brown internally, rather hard and fibrous, difficultly pulverizable, of an agreeable aromatic odour, and a pungent, hot, spicy, permanent taste. The *small galangal* resembles the preceding in shape, but is smaller, not exceeding the little finger in thickness, of a darker colour, and of a stronger taste and smell. The active principles of galangal are a volatile oil, and an acrid resin. Its medical effects are those of a stimulant aromatic; and it may be used for the same purposes as ginger. It was known to the ancient Greeks and Arabians, and entered into numerous compound preparations, some of which have but recently passed out of use. At present the root is very seldom employed. Its dose is from fifteen to thirty grains in substance, and twice as much in infusion.

GALEGA OFFICINALIS. *Goat's Rue.* A perennial herb, growing in the South of Europe, and sometimes cultivated in gardens. It is without smell unless bruised, when it emits a disagreeable odour. Its taste is uneplasantly bitter and somewhat rough; and when chewed, it stains the saliva yellowish-brown. In former times it was much employed as a remedy in malignant fevers, the plague, the bites of serpents, worms, &c.; but it has now fallen into merited neglect. The roots of the *Galega Virginiana*, which is a native of the United States, are said to be diaphoretic and powerfully anthelmintic. They are given in decoction.

GALIUM APARINE. *Cleavers. Goose-grass.* This is an annual, succulent plant, common to Europe and the United States, growing in cultivated grounds, and along fences and hedges. It is inodorous, and has a bitterish, herbaceous, somewhat acrid taste. The expressed juice is said to be aperient, diuretic, and antiscorbutic; and has been used in dropsy, congestion of the spleen, scrofula, and scorbutic eruptions. In the last complaint it has been thought peculiarly useful. Three ounces of the juice may be taken twice a day. The fresh herb, prepared in the form of ointment or of decoction, has been applied externally to scrofulous swellings with supposed advantage.

GALIUM VERUM. *Yellow Ladies Bed-straw. Cheese-rennet.* This species of Galium is perennial, and a native of Europe. The flowers, which are yellow, have a peculiar, agreeable odour, and have sometimes been given in nervous affections, with a view to their supposed antispasmodic powers. The herb is inodorous, but has an astringent acidulous, bitterish taste. The property of coagulating milk was formerly ascribed to it, but is certainly not constant as the experiment has been frequently tried without success. The bruised plant is sometimes used to colour cheese yellow, being introduced into the milk before coagulation. It is also used for dyeing yellow. The roots of this and of most of the other species dye red; and the plant eaten by animals colours the bones like madder. This species of Galium was formerly highly esteemed as a remedy in epilepsy and hysteria, and was applied externally in cutaneous eruptions. It may be employed either in the form of the recently expressed juice, or of a decoction prepared from the fresh plant. Its medical properties, however, are feeble.

Of the American species, the *G. tinctorium* is closely allied in properties to the G. verum. It is said to be useful in cutaneous diseases; and the root is employed by the Indians for staining their feathers and other ornaments red.

GENISTA TINCTORIA. *Dyers' Broom. Dyers' Weed. Green Weed.* A low shrub, growing wild in Europe, and sometimes cultivated in this country in gardens. The flowering tops of the plant are employed to dye a yellow colour, whence its name was derived. Both these and the seeds have been employed in medicine. It is said that they are purgative and even emetic, especially the seeds, which were formerly used as a cathartic in the dose of a drachm and a half. By some authors they are said to be diuretic, and to be useful in dropsy; but it may be a question whether they were not confounded with the seeds and tops of the common broom (*Spartium Scoparium*). Attention was some years since attracted to the plant as a preventive of hydrophobia, for which purpose it was said to have been long used effectually by the peasants of Podolia, the Ukraine, and other provinces of Russia. It was employed in the form of very strong decoction, both internally and as an application to the bitten part; and its use was persevered in for six weeks: but the trials made with it in other parts of Europe have not justified the hopes which were at first entertained. The Russians are said to use it in connexion with the *Rhus coriaria.*

GERANIUM ROBERTIANUM. *Herb Robert.* This species of Geranium grows wild both in Europe and the United States, but is rare in this country; and Pursh states that the American plant is destitute of the heavy smell by which the European is so well known, though the two agree in all other respects. The herb has a disagreeable, bitterish, astringent taste, and imparts its virtues to boiling water. It has been used internally in intermittent fever, consumption, hemorrhages, nephritic complaints, jaundice, &c., has been employed as a gargle in affections of the throat, and has been applied externally as a resolvent to swollen breasts and other tumours.

GINSENG. This is the root of the *Panax quinquefolium*, a perennial herbaceous plant, belonging to the class and order Pentandria Digynia of the sexual system (Polygamia Diœcia, Linn.), and to the natural order Araliaceæ. The stem is smooth, round, about a foot high, and divided at the summit into three leafstalks, each of which supports a compound leaf, consisting of five, or more rarely of three or seven petiolate, oblong obovate, acuminate, serrate leaflets. The flowers are polygamous, small, greenish, and arranged in a simple umbel, supported by a peduncle, which rises from the top of the stem in the centre of the petioles. The calyx is five-toothed, and the corolla composed of five petals. The fruit consists of kidney-shaped, scarlet berries, crowned with the styles and calyx, and containing two, and sometimes three seeds. The plant is indigenous, growing in the hilly regions of the Northern, Middle, and Western States, and preferring the shelter of thick, shady woods. It is a native also of Chinese Tartary. The root is the part employed. This is collected in considerable quantities in Ohio and Western Virginia, and brought to Philadelphia and other cities on the sea-board for the purpose of exportation to China, where it is highly valued. While supplied exclusively from their own native sources, which furnished the root only in small quantities, the Chinese entertained the most extravagant notions of its virtues, considering it as a remedy for all diseases, and as possessing almost miraculous powers in preserving health, invigorating the system, and prolonging life. It is said to have been worth its weight in gold at Pekin; and the first shipments made from North America to Canton, after the discovery of the root in this country, were attended with enormous profits. But the subsequent abundance of supply has greatly diminished its value, and though it still occasionally forms a part of the investments for Canton, it has become an object of less importance than formerly.

The root is fleshy, somewhat spindle-shaped, from one to three inches long, about as thick as the little finger, and terminated by several slender fibres. Frequently there are two portions, sometimes three or more, connected at their upper extremity, and bearing a supposed, though very remote resemblance to the human figure, from which circumstance it is said that the Chinese name *ginseng* originated. When dried, the root is yellowish-white and wrinkled externally, and within consists usually of a hard central portion, surrounded by a soft whitish bark. It has a feeble odour, and a sweet, slightly aromatic taste, somewhat analogous to that of liquorice root. It has not been accurately analyzed, but is said to be rich in gum and starch. It is sometimes submitted, before being dried, to a process of clarification, which renders it semitransparent and horny, and enhances its value as an article of export. The extraordinary medical virtues formerly ascribed to ginseng, had no other existence than in the imaginations of the Chinese. It is little more than a demulcent; and in this country is not employed as a medicine. Some persons, however, are in the habit of chewing it, having acquired a relish for its taste; and it is chiefly to supply the wants of these that it is kept in the shops.

GLECHOMA HEDERACEA. *Ground-ivy.* A small perennial herb, indigenous in Europe and the United States, and growing in shaded grassy places, as in orchards, and along fences and hedges. It belongs to the family of labiate plants, and shares their general properties. The herb was formerly officinal, and still enjoys some credit as a domestic remedy. It has a peculiar disagreeable odour, and a bitterish, rough, somewhat aromatic taste, and imparts its properties to boiling water. From the statements of authors it appears to be gently stimulant and tonic, with perhaps a peculiar direction to the lungs and kidneys. It has also been considered aperient. The complaints in which it has been most used are chronic affections of the pulmonary and urinary organs; and at one time it had considerable reputation as a remedy in consumption. It has also been employed as a vulnerary and errhine. The usual form in which it was administered was that of infusion, of which a quantity was given for a dose containing the virtues of half a drachm or a drachm of the herb.

GLUE. An impure form of gelatin, obtained from various animal substances by boiling them in water, straining the solution, and evaporating it till upon cooling it assumes the consistence of jelly, dividing the soft mass which results into thin slices, and drying it in the open air. Glue, when of good quality, is hard and brittle, of a brown colour, and equally transparent throughout. It softens and swells up very much in cold water, without dissolving; but is readily dissolved by hot water. It is employed chiefly for cementing pieces of wood together, being too impure for the purposes of a test, or for internal use.

GNAPHALIUM MARGARITACEUM. *Cudweed. Life-everlasting.* An indigenous herbaceous perennial, growing in fields and woods, and flowering in August. The herb of this and of the *G. polycephalum*, or *sweet-scented life-everlasting*, is sometimes used in the form of tea by the country people, in diseases of the chest and of the bowels, and in hemorrhagic affections, and externally, in the way of fomentation, in bruises, languid tumours, and other local complaints; but it probably possesses little medical virtue. Shoepf says that it is anodyne. In Europe, different species of Gnaphalium are also occasionally employed for similar purposes.

GOLD. *Aurum.* The preparations of this metal were introduced to the notice of physicians by Dr. Chrestien of Montpellier in 1810. They are employed both internally, and by frictions on the tongue and gums. The principal affections in which they have been recommended are secondary syphilis, syphilitic ulcerations, scrofula, and inveterate eruptions, particularly those of a leprous character. The chief preparations which have been used up to the present time are metallic gold in a finely divided state, the oxide, the chloride, the double chloride of gold and sodium, and the cyanuret of gold. It may be obtained as a *metallic powder*, by precipitating the nitro-muriatic solution of gold by protosulphate of iron, and as an *oxide*, by treating the same solution with an excess of magnesia, and washing the precipitate, first with water, and afterwards with dilute nitric acid. The *chloride* is obtained by dissolving pure gold in three times its weight of nitro-muriatic acid, by the aid of a moderate heat. The solution is evaporated by a gentle heat nearly to dryness, being at the same time stirred with a glass rod. It is in the form of a crystalline mass of a deep red colour. Its solution has a fine yellow tint. Being deliquescent, it requires to be kept in ground stoppered bottles. *The double chloride of gold and sodium* is prepared by dissolving four parts of gold in nitro-muriatic acid, evaporating the solution to dryness, and dissolving the dry mass in eight times its weight of distilled water. To this solution one part of pure decrepitated common salt is added, previously dissolved in four parts of water. The mixed solution is then evaporated to dryness, being in the mean time constantly stirred with a glass rod. This salt is of a golden yellow colour, and, when crystallized, is in the form of long prismatic crystals, inalterable in the air. The *cyanuret of gold* is best obtained, according to M. Oscar Figuier, as follows. (*Journ. de Pharm. XXe. Année*, p. 599.) Prepare the chloride of gold as neutral as possible by repeated solutions and crystallizations; and to the solution of this salt add, very cautiously, avoiding any excess, a solution of *pure* cyanuret of potassium, so long as any precipitate falls. The precipitate, consisting of cyanuret of gold, is to be washed with pure water, and dried in the dark. The solution of the cyanuret of potassium may be obtained pure and free from formiate and carbonate of potassa, by dissolving in water, soon after its preparation and before it has had time to undergo any change, the residue obtained by calcining the yellow ferrocyanate of potassa.

The preparations of gold are decidedly poisonous, though in different degrees. The chloride is most virulent, and, according to Dr. Chrestien, is even more active than corrosive sublimate. In an overdose, it produces pain, inflammation, and even ulceration of the stomach and bowels, and otherwise acts as a corrosive poison. The general effects of these preparations, in moderate doses, is to produce increased fulness and frequency of the pulse, and to augment the urine and insensible perspiration, without interfering with the appetite or the regular action of the bowels; but if the dose is pushed too far, general irritation is apt to be produced, inflammation seizes upon some organ, according to the predisposition of the individual, and fever is developed.

Metallic gold, the oxide, and *simple chloride* are not as much used as the double chloride of gold and sodium. The oxide may be given, in the form of pill, in the dose of a tenth of a grain, in scrofula, and lymphatic swellings, beginning with one pill daily, and afterwards gradually increasing to seven or eight in the 24 hours.

The *chloride of gold and sodium* is the preparation of gold most commonly employed. It may be given in lozenges, each containing the twelfth of a grain, by mixing intimately five grains of the salt with an ounce of powdered sugar, and making the whole with mucilage of tragacanth into a proper mass to be divided into sixty lozenges. Pills, containing the same dose, may be formed by dissolving ten grains of the dried salt in a drachm of distilled water, and forming the solution into a pilular mass with a mixture of four drachms of potato starch and one drachm of gum arabic, to be divided into one hundred and twenty pills. (*Journ. de Pharm. XXe. Année*, p. 648.) For frictions on the gums and tongue, Chrestien recommends the following formula:—Crystallized chloride of gold and sodium, one grain; powdered orris root, deprived of its soluble parts by alcohol and water and dried, two grains. Mix. At first the fifteenth part of this powder is used daily by frictions; afterwards the fourteenth, the thirteenth, &c. until, increasing gradually, the tenth or eighth part is employed. The use of four grains of the salt in this way is said commonly to cure bad cases of recent syphilis, such, for example, as are characterized by the coexistence of chancres, warts, and buboes. In the preparation of this powder, lycopodium may be substituted with advantage for the orris.

The *cyanuret of gold* is employed, like the preceding preparation, mixed with inert powders in frictions, and in the form of pill. The fifteenth of a grain may be rubbed into the gums daily for fifteen days, next the fourteenth of a grain for fourteen days, and so on, increasing until the dose amounts to the eighth or the ninth of a grain. The dose for internal exhibition is the eighteenth of a grain, gradually increased to the eighth of a grain. The cyanuret of gold has been found very useful in the treatment of syphilis and scrofula by M. Pourché, and is said to be less exciting than the double chloride, when used in those diseases. (*Journ. de Pharm. XXe. Année*, p. 599 *et* 649.)

The different medicinal compounds of gold should not be prepared in pill, powder, or otherwise, until they are wanted for use; as they are liable to decomposition when kept. They should be carefully secluded from the light.

HAMAMELIS VIRGINICA. *Witch-hazel.* An indigenous shrub, from five to fifteen feet high, growing in almost all sections of the United States, usually on hills or in stony places, and frequently on the banks of streams. It is remarkable for the late appearance of its yellow flowers, which expand in September or October, and continue till the weather becomes very cold in winter. The fruit, which is a nut-like capsule not unlike the hazelnut, ripens in the following autumn, and is often mingled on the same plant with the new blossoms. The bark has a bitter, astringent, somewhat sweetish and pungent taste. It appears to have attracted notice as a remedy employed by the Indians, who are said to have applied it as a sedative and discutient to painful tumours, and other cases of external inflammation. It is used in the shape of poultice, or as a wash in the form of decoction, in hemorrhoidal affections and ophthalmia. The leaves are said to possess similar properties, and in the state of infusion to be given internally in bowel complaints and hemorrhages. The seeds are black and shining externally, white, oily, and farinaceous within, and are edible like the hazelnut.

HEDERA HELIX. *Ivy.* This well known evergreen creeper is a native of Europe. The fresh *leaves* have a balsamic odour, especially when rubbed, and a bitterish, harsh, unpleasant taste. They are used externally for dressing issues, and, in the form of decoction, have been recommended in seanious ulcers and cutaneous eruptions, particularly tetter and the itch. Dried and powdered, they have been employed in the atrophy of children, and in complaints of the lungs, in the dose of a scruple or more. The *berries*, which have an acidulous, resinous, somewhat pungent taste, are said to be purgative and even emetic. From the trunks of old plants, growing in the South of Europe and the North of Africa, a resinous substance exudes through incisions in the bark, which has been employed in medicine under the name of *ivy gum.* It is in pieces of various sizes, of a dark yellowish-brown colour sometimes inclining to orange, more or less transparent, sometimes of a deep ruby-red colour internally, of a vitreous fracture, pulverizable, yielding a lively orange-yellow powder, of a peculiar not disagreeable odour when heated or inflamed, and of a bitterish resinous taste. Its chief constituent is resin, though some pieces contain a considerable proportion of bassorin, and others large quantities of ligneous matter. It was formerly used as a stimulant and emmenagogue, but is now scarcely employed. Placed in the cavities of carious teeth, it is said to relieve toothach. The *wood* of the ivy, which is light and porous, is sometimes used for making issue-peas.

HELENIUM AUTUMNALE. *False Sunflower. Sneezewort.* An indigenous perennial herbaceous plant, from three to seven feet high, with large golden-yellow compound flowers, which appear in August. It grows in all parts of the United States, flourishing best in meadows, moist fields, and other low grounds. All parts of it are bitter and somewhat acrid, and when snuffed up the nostrils in the state of powder, produce violent sneezing. The leaves and flowers have been recommended as an excellent errhine. Clayton says that the plant is thought to be useful in intermittent fevers.

HERMODACTYLS. *Hermodactyli.* Under this name are sold in the shops of Europe the roots or bulbs of an uncertain plant, growing in the countries about the eastern extremity of the Mediterranean. By some botanists the plant is considered a species of *Colchicum*, and the *C. variegatum*, a native of the South of Europe and the Levant, is particularly indicated by Fée, Geiger, and others; while by authors not less eminent, the roots are confidently referred to the *Iris tuberosa.* They certainly bear a considerable resemblance to the bulb of the Colchicum autumnale, being heart-shaped, channeled on one side, convex on the other, and from half an inch to an inch in length, by nearly as much in breadth. As found in the shops, they are destitute of their outer coat, of a dirty yellowish or brownish colour externally, white and amylaceous within, inodorous, and nearly tasteless, though sometimes slightly acrid. They are often worm-eaten. Their chief constituent is starch, and they contain no veratria. From this latter circumstance, and from their insipidity, it has been inferred that they are probably not derived from a species of Colchicum; but Geiger observes that they may have lost their acrimony by age. They are in fact almost without action upon the system, and are now seldom used; never, we believe, in this country. It is doubted whether they are the *hermodactyli* of the ancients, which were certainly a powerful medicine, operating very much in the same manner with our colchicum, and like it proving useful in gout and rheumatism.

HIBISCUS ABELMOSCHUS. An evergreen shrub, growing in Egypt, and in the East and West Indies, and affording the seeds known under the name of *semen Abelmoschi, alceæ Ægyptiacæ*, and *grana moschata.* These are of about the same size as flaxseed, kidney-shaped, striated, of a grayish-brown colour, of an odour like that of musk, and of a warm somewhat spicy taste. They were formerly considered stimulant and antispasmodic; but are now used only in perfumery. The Arabs flavour their coffee with them. They are said to be sometimes employed in the adulteration of musk.

HYDRASTIS CANADENSIS. *Yellow Root. Orange Root.* This is an indigenous plant, growing in different parts of the United States, but most abundantly beyond the Alleghanies. It flourishes best in rich shady woods. It has a perennial root, and an herbaceous stem, from six inches to a foot high, with two unequal leaves, and a single terminal whitish or rose-coloured flower. The root consists of a tortuous caudex, and numerous long fibres, and is of a bright yellow colour. It is juicy in the recent state, and loses much of its weight when dried. It has a strong, somewhat narcotic odour, and an exceedingly bitter taste. It probably possesses the ordinary virtues of the vegetable bitters, and is said to be popularly employed as a tonic in some parts of the country. In the form of infusion, it has been used in the Western States as a topical application in ophthalmia; and the Indians are said to employ it in the same manner in old ulcers of the legs. The notion of its efficacy in cancer, originating in a report which reached the late Professor Barton, that it was used in the cure of this complaint by the Cherokees, is probably altogether groundless. The Indians employ the juice of the root to stain their clothing, &c., yellow.

HYPERICUM PERFORATUM. *St. John's Wort.* A perennial herb, abundant both in Europe and in this country, often covering whole fields, and proving extremely troublesome to farmers. It is usually from one to two feet high, with leaves, which from the presence of numerous transparent vesicles, appear as if perforated, and have hence given origin to the botanical designation of the plant. The flowers, which are numerous and of a deep yellow colour, appear during the summer from June to August. The flowering summits are the part used, though the unripe capsules are possessed of the virtues of the plant in an equal degree, and the seeds are said to be even stronger. St. John's wort has a peculiar balsamic odour, which is rendered more sensible by rubbing or bruising the plant. Its taste is bitter, resinous, and somewhat astringent. It imparts a yellow colour to cold water, and reddens alcohol and the fixed oils. Its chief constituents are volatile oil, a resinous substance, tannin, and colouring matter. As a medicine, it was in high repute among the ancients, and was much employed by the earlier modern physicians.

Among the complaints for which it was used, were hysteria, mania, intermittent fever, dysentery, gravel, hemorrhages, pectoral complaints, worms, and jaundice; but it was, perhaps, most highly esteemed as a remedy in wounds and bruises, for which it was employed both internally and externally. It is difficult to ascertain its exact value as a remedy; but from its sensible properties, and from the character of the complaints in which it has been thought useful, it may be considered, independently of its astringency, as somewhat analogous in medical powers to the turpentines. It formerly enjoyed great reputation for the cure of demoniacs; and the superstition still lingers among the vulgar in some countries. At present, the plant is scarcely used except as a domestic remedy. The summits were formerly given in the dose of two drachms or more. A preparation was at one time officinal, under the name of *oleum hyperici*, made by treating them with a fixed oil. It has a red colour, and is still used in many families as a sovereign remedy for bruises.

ILEX. *Holly.* Several species of this genus of plants are employed in different parts of the world. The *I. Aquifolium*, or *common European holly*, has attracted much attention in France. It is usually a shrub, but in some places attains the magnitude of a middling-sized tree. Different parts of it are used. The viscid substance called birdlime is prepared from the *inner bark.* The *leaves*, which are of a bitter, somewhat austere taste, were formerly much esteemed. They were considered diaphoretic, and in the form of infusion were employed in catarrh, pleurisy, small-pox, gout, &c. Within a few years they have gained some reputation in France as a cure for intermittents, being considered by some as equal, if not superior to Peruvian bark; but the first reports in their favour have not been fully confirmed. They were used in the form of powder, in the dose of a drachm two hours before the paroxysm; and this dose was sometimes repeated frequently in the apyrexia. Their febrifuge virtues are said to depend on a peculiar bitter principle, for which the name of *ilicin* has been proposed. The *berries* are about the size of a pea, red and bitter, and are said to be purgative, emetic, and diuretic. Ten or twelve of them will usually act on the bowels, and sometimes vomit. Their expressed juice has been used in jaundice.

The *Ilex opaca*, or *American holly*, is a middling-sized evergreen tree, growing throughout the Atlantic section of the United States, and especially abundant in New Jersey. It is so similar to the European plant, that it is, by some writers, considered as the same species. It is said to possess the same medical properties.

The *Ilex Paraguaiensis*, or *I. Mate* of St. Hilaire, is the plant which yields the celebrated *Paraguay tea*, so extensively consumed as a beverage in the interior of South America. The leaves, which are the part used, have a balsamic odour, and a bitter taste, and are usually at first disagreeable to the palate. They have a pleasant corroborant effect upon the stomach; but when very largely taken, are said to purge and vomit. They are used in the form of infusion.

The *Ilex vomitoria* of Aiton and Linn., the *I. Cassina* of Michaux, is a handsome evergreen shrub, growing in our Southern States, and especially abundant along the southern coast of Florida. It is the *cassina* of the Indians, who formerly employed a decoction made from the toasted leaves, called *black drink*, both as a medicine, and as a drink of etiquette at their councils. It acts as an emetic. The leaves of the *Ilex Dahoon* of Walter and Michaux, have similar properties, and are also said to have entered into the composition of the black drink.

ILLICIUM FLORIDANUM. *Florida Anisetree.* This is an evergreen shrub or small tree, growing in Florida, along the coast which bounds the Gulf of Mexico. The bark, leaves, and probably also the seed vessels, are endowed with a spicy odour and taste analogous to anise, and might probably be used for the same purposes as this aromatic. It is a question worthy of investigation, whether the capsules of this plant might not be substituted for those of the *Illicium anisatum* or *star aniseed*, which yield much of the oil used in this country under the name of *oil of anise.* (See *Anisum.*) Another species of Illicium, the *I. parviflorum*, a shrub found by Michaux in the hilly regions of Georgia and Carolina, has a flavour closely resembling that of sassafras root.

IMPATIENS FULVA and IMPATIENS PALLIDA. *Touch-me-not. Jewel-weed. Balsam-weed.* These two species of Impatiens, considered by Michaux as varieties of the *I. Nolitangere* of Linnæus, are indigenous, annual, succulent plants, from two to four feet high, growing in low moist grounds in all parts of the Union, and flowering in July and August. They may be known by their tender, juicy, almost transparent stems; by their yellow flowers, which in one species are pale and sparingly punctate, in the other, are deeper coloured and crowded with dark spots; and by their capsules, which burst elastically and curl up with the slightest pressure. They probably possess properties similar to those of the *I. Nolitangere* of Europe, which has an acrid burning taste, and when taken internally, acts as an emetic, cathartic, and diuretic, though considered a dangerous plant, and therefore little used. Dr. Ruan, of Philadelphia, has informed us that he has employed, with great advantage, in piles, an ointment made by boiling the American plants, in their recent state, in lard. The flowers may be used for dyeing a yellow colour. The *I. Balsamina* or *balsam-weed*, *touch-me-not*, *&c.*, of the gardens, is said to possess similar properties with the other species.

IMPERATORIA OSTRUTHIUM. *Masterwort.*. An umbelliferous plant, indigenous in the South of Europe. The root has a strong odour, similar to that of Angelica, and a pungent, biting, aromatic taste, attended with a flow of saliva, and followed by a glowing warmth which remains long in the mouth. It was formerly considered alexipharmic, stomachic, corroborant, emmenagogue, diuretic, and diaphoretic; and was used in a wide circle of complaints with so much supposed success as to have gained for it the title of *divinum remedium.* The fact, however, appears to be, that it is merely a stimulant aromatic, analogous but inferior to Angelica, which has nearly superseded it in European practice. In this country, it is unknown as a remedy, and its vulgar name has been applied to another plant.

INDIAN RED. A purplish-red pigment, brought from the island of Ormus in the Persian Gulf. It is a *red ochre*, and owes its colour to the red oxide of iron.

INDIGO. This well known and highly important dye-stuff, is obtained from various species of *Indigofera*, especially the *I. tinctoria*, *I. Anil*, and *I. argentea;* and is afforded also by other plants, such as the *Wrightia tinctoria*, *Isatis tinctoria*, *Polygonum*, *tinctorium*, *Galega tinctoria*, &c. In the process of preparing it, the plant is macerated in water; fermentation takes place; the liquor becomes of a greenish colour, and in due time is decanted; the colouring principle dissolved by the water absorbs oxygen from the air, and assumes a blue colour, becoming at the same time insoluble; a gradual precipitation takes place, favoured by the addition of lime-water or an alkaline solution; and finally, the precipitated matter having been washed upon linen filters, is dried, shaped usually into cubical masses, and sent into market. Most of the indigo consumed in dyeing, is brought from the East Indies, though considerable quantities are brought also from Guatemala and the northern coast of South America. Indigo is insoluble in water or alcohol, but is readily dissolved by sulphuric acid, which, without destroying its blue colour, so far alters its nature as to render it freely soluble in water, and thus affords a convenient method of applying it to the purposes of dyeing. The solution in sulphuric acid is sometimes kept in the shops under the name of *sulphate of indigo.* According to Berzelius, indigo contains, among other ingredients, four distinct principles;—1. a substance resembling gluten; 2. a brown colouring substance; 3. a red colouring substance; and 4. a blue colouring substance, which is the principle upon which its value as a material for dyeing depends, and which seldom constitutes so much as one half of the indigo of commerce.

Indigo has recently been employed by Dr. Moritz Strahl, with asserted advantage, in epilepsy, hysteria, amenorrhœa, and nephritic pains. In the epileptic cases it was given in the quantity of one drachm, gradually increased to an ounce, daily. During the employment of the remedy the perspiration is bluish, and the urine green. (*Journ. de Pharm.* vi. 328—from *Gräf and Walter's Journal.*)

IODIDE OF AMMONIUM. *Ammonii Iodidum. Hydriodate of Ammonia.* This salt is formed by saturating liquid hydriodic acid with caustic ammonia, and evaporating the solution. It forms a deliquescent saline mass, which crystallizes with difficulty in cubes. It is mentioned by Dr. Pennock as a good remedy in some cases of lepra and psoriasis, made up into an ointment. (*Amer. Journ. of Med. Sciences*, xv. 374.) The proportions employed are from a scruple to a drachm of the salt to an ounce of lard; the weaker preparation being used when the disease is recent, the stronger when it is chronic. The ointment was employed in frictions in the amount of half an ounce, morning and evening. As the iodide decomposes by exposure to the air, the ointment should be kept in well stopped bottles.

IODIDE OF IRON. *Ferri Iodidum.* The protiodide of iron has within a few years been introduced into medical practice. It was first used in Philadelphia by Dr. Samuel Jackson, at whose request it was prepared in the form of solution by Mr. E. Durand. The formula of Mr. Durand, which is an improvement on that of Baup and Caillot, is as follows:—Take of Iodine *ten drachms;* Iron Filings, perfectly pure and unoxidized, *five drachms;* Distilled Water *twelve and a half fluidounces.* Put the iodine in a porcelain capsule, with half the water, and add the filings by small portions, stirring the mixture with a glass rod. The combination soon takes place, and the mixture acquires an orange colour, gradually deepening to a dark red. When the whole of the iron has been added, heat the mixture slowly by means of a sand-bath or spirit-lamp, and stir it constantly. When the union has been completed, the solution becomes colourless, and in this state is filtered; and the residue on the filter is washed with the remaining distilled water, previously heated to the boiling point. The amount of liquid obtained measures twelve and a half fluidounces, and contains about twelve and a half drachms of iodide of iron, or a drachm of the iodide to the fluidounce.

This liquid, in which the iodide of iron may be supposed by solution to be converted into the hydriodate of the oxide, is liable to the defect of becoming deep red by standing; some iodine being set free, and oxide of iron precipitated. We are informed by Mr. Durand, that this defect is remedied by letting the solution stand on some pure iron filings, which constantly reproduce the iodide of iron with any free iodine as soon as disengaged. Iodide of iron has a greenish-black colour, and an austere, astringent taste. It is very deliquescent, and, therefore, requires to be kept in well stopped bottles. Its solution, when well prepared, is of a light orange colour. It acts as a tonic and alterative, and may be given in various diseases in which it is desirable to stimulate the absorbent system; as in scrofulous complaints, and visceral obstructions, attended with deficient action. It has been successfully employed by M. Pierquin in amenorrhæa and leucorrhœa. (*Journ. Phil. Coll. of Pharm.* vi. 178.) The dose of the standard solution of Mr. Durand, which may be called *Liquor Ferri Hydriodatis*, is from five to ten drops, three times a day, given in a little water. M. Pierquin recommends its use in lozenges, made up with powdered saffron and white sugar, each containing a quarter of a grain of the solid salt. For enemata, injections into the vagina, and lotions, two drachms may be dissolved in a pint of water.

IODIDE OF SULPHUR. *Sulphuris Iodidum.* This iodide is prepared by heating slightly a mixture of four parts of iodine with one of sublimed sulphur. The excess of iodine is driven off, and the iodide of sulphur remains, as a grayish mass, very deliquescent and readily decomposed by water. It has been used by M. Biett as an external application, mixed with lard in the proportion of a scruple or half a drachm to the ounce of the fat, for the cure of porrigo, and of certain tuberculous affections of the skin. A drachm may be employed at each friction.

IODIDE OF ZINC. *Zinci Iodidum.* This iodide may be formed by digesting an excess of zinc, in small pieces, with iodine diffused in water. Combination takes place, and by evaporation, a deliquescent, very soluble saline mass is obtained, having a metalline, styptic taste, resembling that of sulphate of zinc. It may also be obtained by heating in a matrass a mixture of 20 parts of zinc and 170 of iodine, and subliming into a vial. When thus prepared, it is in the form of white needles.

Iodide of zinc has occasionally been employed, in the form of ointment, as a substitute for the iodide of potassium, and in solution as an astringent injection, in the proportion of one or two grains to the fluidounce of water. Dr. Ure has proposed an ointment to be made by rubbing up a drachm of the iodide with an ounce of lard, to be applied in the quantity of a drachm twice a day to tumours, in place of the ointment of iodide of potassium.

IODO-HYDRARGYRATE OF POTASSIUM. It has been found by chemists that different iodides will unite together in definite proportions, forming compounds which are called by Berzelius double iodides. Bonsdorf of Finland, and Dr. Hare of Philadelphia, with greater reason, have viewed these combinations as a peculiar kind of salts, in which one of the iodides performs the part of an acid, the other, of a base. The substance, the the name of which is given at the head of this article, is one of these compounds, and was presented to the notice of the profession, as a new remedy of remarkable powers, in February 1834, by Dr. William Channing of New York. (*Amer. Journ. of Med. Sci.* xiii, 388.) It consists of the biniodide of mercury acting as an acid, united with the iodide of potassium as a base. But as these two iodides unite in at least two proportions, it is necessary to indicate the particular combination employed by Dr. Channing in his therapeutic experiments.

In a difficult case of pectoral disease, in which the ordinary remedies had failed, Dr. Channing determined to make trial of one of the iodides of mercury. He selected the biniodide; and in order to have it in the liquid form, it being insoluble in water, he dissolved it in a solution of iodide of potassium (hydriodate of potassa). He was struck with the chemical changes which the compound solution underwent; and on pursuing his observations he found that the two iodides really united by the intervention of the water; for by the assistance of an operative chemist, he was enabled by evaporation to obtain them in union in the form of straw-coloured, needleform, deliquescent crystals. He next found, upon consulting the European authorities, that Bonsdorf, who had taken the lead in investigating similar compounds, had discovered the same salt in 1826.

Dr. Channing analyzed the salt with which he experimented, and found that it consisted of one equiv. of biniodide of mercury, and two of iodide of potassium. This he determined by ascertaining that an aqueous solution of a little more than eight grains of iodide of potassium would dissolve, and combine with, eleven grains of biniodide of mercury, without being liable to decomposition when largely diluted with water.

The combination here indicated corresponds with one of the double iodides of mercury and potassium, as described by Thenard. (*Traité de Chimie*, 6ème *Ed.* iii. 493.) The other is represented by this author as consisting of a single equiv. of each iodide, and appears to correspond with the deliquescent straw-coloured salt obtained by Dr. Channing. When copiously diluted with water, every two equivalents of the compound let fall one equiv. of the mercurial iodide; thus evidently converting the salt into the medicinal double iodide. The same decomposition by the use of abundance of water is noticed by Dr. Channing.

Dr. Channing attributes to the new remedy which he has brought forward, the effects of diffusing excitement, and equallizing the circulation, even in the minutest vessels. In the different cases in which he tried it, he thought he saw evidence of its favourable influence on the lungs, in allaying cough and improving expectoration; on the alimentary canal, in restoring the healthy secretions; on the kidneys, in reviving their activity; on the skin and cellular tissue, in cicatrizing superficial ulcerations; and on the absorbent and exhalent systems, in causing the disappearance of effused fluid. The principal diseases in which he found it useful were chronic bronchitis, hooping cough, tonsillitis, chronic gastro-enteritis, dyspepsia, ascites, anasarca, amenorrhœa, leucorrhœa, eruptions, and scrofula. In some cases of phthisis, it mitigated the symptoms and appeared to prolong life. Such a wide therapeutic application is enough to stagger belief; and indeed we may remark that our strongest objection to these statements in relation to the medicine is, that it has appeared to effect so much.

The average dose of the remedy may be stated at the twelfth of a grain three times a day; but in peculiar constitutions, not more than the forty-eighth, the ninety-sixth, or even the two-hundredth of a grain daily can be borne. For the convenience of physicians who may wish to make trial of the remedy, we give the following formula, deduced from the statements in Dr. Channing's paper. Take of iodide of potassium, three and a half grains; biniodide of mercury (red iodide), four and a half grains; distilled water, a fluidounce. Dissolve first the iodide of potassium and then the biniodide of mercury in the water. The compound salt in this solution may be assumed to amount to eight grains, though there is a small excess of the iodide of potassium. Of the solution, from two to five drops, containing from the thirtieth to the twelfth of a grain, may be given three times a day.

IRISH MOSS. *Carrageen. Fucus crispus*, Linn. *Sphærococcus crispus*, Agardh. *Chondrus crispus*, Greville. This moss grows upon rocks and stones on the coasts of Europe, and is said also to be a native of the United States. It abounds on the southern and western coasts of Ireland. It consists of a flat, slender, cartilaginous frond, three or four inches in length, dilated and very much subdivided at the extremity, with linear divisions, and more or less curled up, so as much to diminish its apparent length. As kept in the shops, it is yellowish and translucent, of a feeble odour, and nearly tasteless. It is insoluble in cold, but is dissolved by boiling water. According to Mr. Feuchtwanger, it contains starch and a large proportion of pectic acid (pectin), with compounds of sulphur, chlorine, and bromine, and some oxalate of lime. (*Journ. of the Phil. Col. of Pharm.* vi. 204.) It is nutritive and demulcent, and, being easy of digestion and not unpleasant to the taste, forms a useful article of diet in cases in which the farinaceous preparations, such as tapioca, sago, arrow-root, barley, &c., are usually employed. It has been particularly recommended in chronic pectoral affections, scrofulous complaints, dysentery, and disorders of the kidneys and bladder. It may be used in the form of decoction, made by boiling a pint and a half of water with half an ounce of the moss down to a pint. Sugar and lemon juice may usually be added to improve the flavour. Milk may be substituted for water, when a more nutritious preparation is required. It is recommended to steep the moss for a few minutes in cold water before submitting it to decoction. Any unpleasant flavour which it may have acquired from the contact of foreign substances is thus removed.

ISATIS TINCTORIA. *Woad. Pastel.* A biennial plant, indigenous in Europe, where it is also cultivated. The leaves have a fugitive pungent odour, and an acrid very durable taste, and have been used in scorbutic affections, jaundice, and other complaints; but the plant is valuable only as the source of a blue dye-stuff, called *woad*, which has been long employed in Europe, though at present nearly superseded by indigo. The leaves are prepared by grinding them to a paste, which is made into balls, placed in heaps, and allowed to ferment. When the fermentation is at an end, the mass falls into a coarse powder, which is the dye-stuff in question.

KALMIA LATIFOLIA. *Laurel. Mountain-laurel. Broad-leafed-laurel. Calico-bush.* This well known evergreen inhabits all sections of the United States, but is particularly abundant on the sides of hills and mountains, which it adorns in summer with its elegant flowers. It is from three to ten feet in height. The leaves are endowed with poisonous, narcotic properties, and have been used in medicine. They are said to prove fatal to sheep and some other animals, but are eaten with impunity by deer, goats, and partridges. Dr. Barton states in his "Collections," that the Indians sometimes use a decoction of the leaves to destroy themselves. It is said that death has been occasioned by eating the flesh of partridges and pheasants which have fed upon them during winter. Dr. Shoemaker has published, in the North American Medical and Surgical Journal, two cases of poisoning which resulted from eating a pheasant, in the craw of which laurel leaves were found. The symptoms were nausea, temporary blindness, pain in the head, difficult breathing, pallid countenance, cold extremities, and very feeble pulse, which in one case was for some time absent at the wrist, in the other beat only forty strokes in the minute. In both instances relief was afforded by vomiting produced by a tablespoonful of flour of mustard mixed with warm water.

Dr. Barton was informed that the powdered leaves were employed by an empyric with success in certain states of fever; and Dr. Thomas, in an inaugural dissertation, published at Philadelphia, A. D. 1802, states that a case of diarrhœa, of eight weeks duration, was cured by a decoction made by boiling an ounce of the leaves in eight ounces of water down to four ounces. Thirty drops were given six times a day; but this quantity produced vertigo, and the dose was afterwards repeated only four times daily. The leaves are said also to have been used advantageously in syphilis. Externally applied in the shape of ointment or decoction, they have been found useful in tinea capitis, psora, herpes, and other cutaneous affections; but some caution is necessary in their application, as, according to Dr. Barton, nervous symptoms have resulted from the external use of the decoction. Dr. Bigelow has seen the recently powdered leaves given in doses of from ten to twenty grains, without perceptible effect.

It is probable that the other species of Kalmia—as the *K. angustifolia*, or *sheep-laurel*, and the *K. glauca*, or *swamp-laurel*, have properties identical with those of the *K. latifolia*.

LABDANUM. *Ladanum.* A resinous substance obtained from various species of Cistus, especially the *C. Creticus*, *C. ladaniferus*, and *C. laurifolius*, small evergreen shrubs, inhabiting the islands of the Grecian Archipelago, and the different countries bordering on the Mediterranean. Upon the leaves and branches of these shrubs a juice exudes, which is collected by means of an instrument resembling a rake, with leather thongs instead of teeth, which is drawn over the plant. The juice adheres to the pieces of leather and is afterwards separated. It is said that labdanum was formerly collected by combing the beards of goats which had been browsing upon the leaves of the cistus. It comes chiefly from the Grecian islands. Two varieties exist in commerce. The *purest labdanum* is in masses of various sizes, sometimes weighing several pounds, enclosed in bladders, of a dark-red almost black colour externally, grayish internally when first broken, of the consistence of a plaster, softening in the hand and becoming adhesive, of an agreeable balsamic odour, similar to that of amber, and of a bitter, balsamic, somewhat acrid taste. It is very inflammable, burning with a clear flame. On exposure it becomes dry, porous, and brittle. Little of this variety is found in the markets. *Common labdanum* is in pieces of a contorted or spiral form, light, porous, blackish-gray, hard and brittle, not softening between the fingers, similar in odour and taste to the preceding variety, but less inflammable, and mixed with much sand and other earthy matter, which are obvious to the sight. Guibourt found in 100 parts of the labdanum in masses, 86 parts of resin with a little volatile oil, 7 parts of wax, 1 of watery extract, and 6 of earthy substances and hair. In the contorted variety, Pelletier found 20 per cent. of resin, 3.6 of gum with malate of lime, 0.6 of malic acid, 1.9 of wax, 1.9 of volatile oil including loss, and 72 of ferruginous sand.

Labdanum is a stimulant expectorant, and was formerly given in catarrhal and dysenteric affections. At present it is employed only as an ingredient in plasters, and seldom even for that purpose in the United States. It is sometimes used in fumigation.

LAC. A resinous substance obtained from several trees growing in the East Indies, particularly from the *Croton lacciferum*, and two species of Ficus, the *F. religiosa* and *F. Indica.* It is found in the form of a crust surrounding the twigs or extreme branches, and is generally supposed to be an exudation from the bark, owing to the puncture of an insect belonging to the genus *Coccus*, and denominated *C. Lacca.* By some it is thought to be an exudation from the bodies of the insects themselves, which collect in great numbers upon the twigs, and are embedded in the concreted juice, through which the young insects eat a passage and escape. Several varieties of lac are known in commerce. The most common are *stick lac*, *seed lac*, and *shell lac.*

Stick lac is the resin as taken from the tree, still encrusting the small twigs around which it originally concreted. It is of a deep reddish-brown colour, of a shining fracture, translucent at the edges, inodorous, and of an astringent, slightly bitterish taste. Its external surface is perforated with numerous minute pores, as if made by a needle; and when broken it exhibits manyo blong cells, often containing the dead insect. When chewed, it colours the saliva, and when burnt, diffuses a strong agreeable odour. It imparts a beautiful red colour to the saliva, and is in great measure soluble in alcohol. Little of this variety is imported.

Seed lac consists of minute irregular fragments broken from the twigs, and partially exhausted by water. It is of a light or dark brown colour, inclining to red or yellow, feebly shining, almost tasteless, and capable of imparting to water less colour than the stick lac, sometimes scarcely colouring it at all. It is occasionally mixed with small fragments of the twigs.

Shell lac is prepared by melting the *stick* or *seed lac* previously deprived of its soluble colouring matter, straining it, and pouring it upon a flat smooth surface to harden. It is in thin fragments of various sizes, from half a line to a line thick, often somewhat curved, of a lighter or darker brown colour, inclining more or less to red or yellow, shining, more or less transparent, hard and brittle, inodorous and insipid, insoluble in water, but easily and almost entirely soluble in alcohol, especially with the aid of heat.

A variety of lac is mentioned by writers, in the form of cakes, called cake or lump lac (*lacca in placentis*); but this is at present rare in commerce.

According to John, lac consists of resin, colouring matter, a peculiar principle insoluble in alcohol, ether, or water, called *laccin*, a little wax, and various saline matters in small proportion. The resin, according to Unverdorben, consists of several distinct resinous principles differing in their solubility in alcohol and ether. The laccin is nearly or quite wanting in the *shell lac*, which also contains scarcely any of the colouring principle. Mr. Hatchet found in *stick lac* 68 per cent. of resin and 10 of colouring matter; in *seed lac* 88.5 per cent. of resin and 2.5 of colouring matter; in *shell lac* 90.9 per cent. of resin and 0.5 of colouring matter. The other constituents, according to this chemist, are wax and gluten, besides foreign matters.

Lac in its crude state is slightly astringent, and was formerly used in medicine. At present it is not employed. Shell lac is wholly inert. Stick lac and seed lac are used on account of the colouring principle which they contain. Shell lac, as well as the other varieties deprived of their colouring matter, is applied to numerous purposes in the arts. It is the chief constituent of sealing wax. The best *red sealing wax* is made by melting together, with a very gentle heat, 48 parts of shell lac, 19 of Venice turpentine, and 1 of balsam of Peru, and mixing with the melted mass 32 parts of finely powdered cinnabar. But common rosin is often substituted in part for the lac, and a mixture of red lead and chalk for the cinnabar. The best *black sealing wax* consists of 60 parts of lac, 10 of turpentine, and 30 of levigated bone black; the best *yellow sealing wax* of 60 parts of lac, 12 of turpentine, and 24 of chromate of lead. (*Berzelius.*) Lac is also used as a varnish, and forms an excellent cement for broken porcelain and earthenware.

LAKES. These are compounds of vegetable or animal colouring principles with alumina or metallic oxides, and are usually obtained by adding alum, or permuriate of tin, to the solution of the colouring matter in water, and precipitating by means of an alkali. The alumina or oxide of tin unites with the colouring matter at the moment of separation, and forms an insoluble compound. Lakes are obtained in this way from cochineal, madder, Brazil wood, seed lac, French berries, &c. They are used in painting.

LAURUS BENZOIN. *Spice-wood. Spice-bush. Fever-bush.* An indigenous shrub, from four to ten feet high, growing in moist, shady places, in all parts of the United States. Its flowers appear early in spring, long before the leaves, and are succeeded by small clusters of oval berries, which when ripe, in the latter part of September, are of a shining crimson colour. All parts of the shrub have a spicy, agreeable flavour, which is strongest in the bark and berries. The small branches are sometimes used as a gently stimulant aromatic, in the form of infusion or decoction. They are said to be employed in this way by the country people, as a vermifuge, and an agreeable drink in low fevers. Dr. William Barton says that the bark, as he has been informed, is extensively used in the country, and with much success, in intermittents. The berries, dried and powdered, were sometimes substituted, during the revolutionary war, for allspice. According to Dr. Drake, the oil of the berries is used as a stimulant.

LEDUM PALUSTRE. *Marsh Tea. Rosmarinus sylvestris.* A small evergreen shrub, growing in swamps and other wet places, in the northern parts of Europe, Asia, and America, and in the mountainous regions of more southern latitudes. The leaves have a balsamic agreeable odour, and an aromatic, camphorous, bitter taste; and contain, among other ingredients, volatile oil and tannin. They are thought to possess narcotic properties, and have been employed in exanthematous diseases to allay febrile irritation, in hooping-cough, in dysentery, and in various cutaneous affections, particularly leprosy and scabies. In complaints of the skin, they are used both internally and externally, in the form of decoction. When placed among clothes, they are said to prevent the attacks of moths. In Germany, they are sometimes substituted for hops in the preparation of beer. The *Ledum latifolium*, or *Labrador tea*, which is a larger plant than the preceding, is a native of North America, growing in damp places in Canada and the northern parts of the United States. The leaves, as in the former species, have an agreeable odour and taste, and are esteemed pectoral and tonic. They are said to have been used as a substitute for tea during the war of independence.

LIATRIS SPICATA. *Gay-feather. Button Snakeroot.* An indigenous perennial plant, growing in natural meadows and moist grounds throughout the Middle and Southern States. It has a tuberous root, and an erect annual stem, which terminates in a spike of beautiful, purple, compound flowers, which appear in August. The root is said by Schoepf to have a terebinthinate odour, and a warm, bitterish, terebinthinate taste; to be possessed of diuretic properties; and to be useful in gonorrhœa and sore throat, being employed internally in the shape of decoction in the former complaint, and as a gargle in the latter. Pursh informs us, that the *L. scariosa*, and *L. squarrosa*, are known in Virginia, Kentucky, and the Carolinas, by the name of *Rattlesnake's master;* and that their roots are employed to cure the bite of the rattlesnake, being bruised and applied directly to the wound, while their decoction in milk is taken internally. According to Dr. William Barton, all the tuberous-rooted species of Liatris are active plants, and appear to be diuretic.

LIGUSTICUM LEVISTICUM. *Lovage.* An umbelliferous plant, growing wild in the South of Europe, and cultivated in gardens. The whole plant has a strong, sweetish, aromatic odour, and a warm pungent taste. When wounded it emits a yellow opaque juice, which concretes into a brownish resinous substance not unlike opopanax. The roots, stem, leaves, and seeds, have all been employed; but the last have the aromatic properties of the plant in the highest degree. They are small, ovate-oblong, somewhat flattened, curved, strongly ribbed, and of a yellowish-brown colour. The medical properties of lovage are closely analogous to those of angelica. It is a stimulant aromatic, and has been employed as a carminative, diaphoretic, and emmenagogue. The best form for administration is that of infusion.

LIGUSTRUM VULGARE. *Privet.* A shrub from four to ten feet in height, growing wild both in Europe and the United States, usually in hedges, and by the roadside. The *leaves*, which have an astringent, bitter taste, and the *flowers*, which are small, snow-white, and of an agreeable odour, have been used, in the form of decoction, in sorethroat, and aphthous and scorbutic ulceration of the mouth. The *berries* are black, have a sweetish, bitter taste, and are said to possess purgative properties, and to colour the urine brown. They are sometimes used for dyeing.

LILIUM CANDIDUM. *Common White Lily.* This well known plant is a native of Syria and Asia Minor, but has been long cultivated in gardens. The bulb, which consists of imbricated fleshy scales, is without odour, but has a peculiar, disagreeable, somewhat bitter and mucilaginous taste. It contains much mucilage, and a small proportion of an acrid principle, which is dissipated or destroyed by roasting or boiling. In the recent state it is said to have been employed with advantage in dropsy. Boiled with water or milk it forms a good emollient cataplasm, more used in popular than in regular practice. The flowers have an agreeable odour, which they impart to oil or lard; and an ointment or liniment is sometimes prepared from them, and used as a soothing application in external inflammations.

LIQUIDAMBAR STYRACIFLUA. *Sweet-gum.* An indigenous tree, growing in different parts of the United States from New England to Louisiana, and flourishing also in Mexico, where, as well as in our Southern States, it sometimes attains a great magnitude. In warm latitudes a balsamic juice flows from its trunk when wounded. This has attracted some attention in Europe, where it is known by the name of *liquidamber*, or *copalm balsam*, and is sometimes, though erroneously, called *liquid storax*. It is not afforded by the trees which grow in the Middle States, and is obtained from Mexico and Louisiana. It is a liquid of the consistence of thin honey, more or less transparent, of a yellowish colour, of a peculiar, agreeable, balsamic odour, and a bitter, warm, and acrid taste. By cold it becomes thicker and less transparent. It concretes also by time, assuming a darker colour. According to M. Bonastre, it contains a colourless volatile oil, a semi-concrete substance which rises in distillation and is separated from the water by ether, a minute proportion of benzoic acid, a yellow colouring substance, an oleo-resin, and a peculiar principle, insoluble in water and cold alcohol, for which M. Bonastre proposes the name of *styracine*. The proportion of benzoic acid is greatly increased by time. Mr.

Hodgson obtained from a specimen which he examined 4.2 per cent. (*Journ. of the Phil. Col. of Pharm.* vi. 190.)

Another product is said to be obtained from the same tree by boiling the young branches in water, and skimming off the fluid which rises to the surface. It is of a thicker consistence and darker colour than the preceding, is nearly opaque, and abounds in impurities. This also has been confounded with liquid storax, which it resembles in properties, though derived from a different source.

Liquidamber may be employed for the same purpose as storax, but is very seldom used, and is almost unknown in the shops of the United States.

LITHOSPERMUM OFFICINALE. *Gromwell. Milium Solis.* A European perennial, the seeds of which are ovate, of a grayish-white or pearl colour, shining, rather larger than millet seeds, and of a stony hardness, from which the generic name of the plant originated. From an opinion formerly prevalent, that nature indicated remedies adapted to certain diseases by some resemblance between the remedy and the character of the complaint or of the part affected, the seeds of this plant were applied to the treatment of calculous disorders; and they retained their ground in the estimation of physicians as a diuretic, useful in complaints of the urinary passages, long after the superstitious notion in which their use originated had been abandoned. But they are at present considered nearly inert, and are not employed.

LYCOPODIUM CLAVATUM. *Club-moss.* The capsules of this moss, and of others belonging to the same genus, contain a fine dust or powder, which is collected in Switzerland and Germany, and used in the shops of Europe under the name of *lycopodium*, or *vegetable sulphur.* This powder is considered by some as the pollen of the plant, by others as the seed. It is extremely fine, very light, of a delicate yellow colour, inodorous and tasteless, and exceedingly inflammable, so much so that it takes fire like gunpowder when thrown upon a burning body. It is said to be often adulterated with the pollen of the pines and firs, and, what is much worse, with talc and starch. In medicine, it is used as an absorbent application to excoriated surfaces, especially those which occur in the folds of the skin in infants. In pharmacy, it answers the purpose of facilitating the rolling of the pilular mass, and of preventing the adhesion of the pills when formed. It is not much used in this country. The moss itself, from which the powder is derived, has been esteemed diuretic, antispasmodic, &c.; and has been employed, in the form of decoction, in rheumatism, epilepsy, and complaints of the lungs and kidneys; but it has fallen into discredit.

MADAR or MUDAR. See CALOTROPIS GIGANTEA.

MANDRAGORA OFFICINALIS. *Atropa Mandragora*, Linn. *Mandrake. Mandragora.* A perennial European plant, with a spindleshaped root, which is often forked beneath, and is therefore compared, in shape, to the human figure. In former times this root was supposed to possess magical virtues, and was used as an amulet to promote fecundity, &c.; and the superstition still lingers among the vulgar in some parts of Europe. The plant is a poisonous narcotic, somewhat similar in its properties to belladonna, to which it is botanically allied. It was much used by the ancients, with a view to its narcotic effects; and the root has been recommended by some eminent modern physicians, as an external application to scrofulous, scirrhous, and syphilitic tumours. It is unknown as a remedy in the United States.

MEDEOLA VIRGINICA. *Indian Cucumber.* An indigenous perennial herb, growing in all parts of the United States. The root, which in shape and flavour bears a strong resemblance to a small cucumber, is said by Pursh to be eaten by the Indians. According to the late Professor Barton, it has been thought useful in dropsies, and probably possesses diuretic properties. It is figured and described by Dr. William Barton in his Medical Botany.

MELILOTUS OFFICINALIS. *Melilot.* An annual or biennial plant, indigenous in Europe, and growing also in this country. We have two varieties, one with yellow, the other with white flowers, which are considered by some as distinct species. The plant when in flower has a peculiar sweet odour, which by drying becomes stronger and more agreeable, somewhat like that of the tonka bean. Indeed, according to M. Guillemette, the odorous principle of the two substances is identical. (*Journ. de Pharm.* xxi. 172.) The taste of melilot is slightly bitterish. It has little medical power, and, though formerly recommended in various diseases, is at present not employed internally. As a local application, it is used, in the form of decoction or cataplasm, in moderate inflammations, though probably with little other advantage than such as results from the combination of warmth and moisture.

MESEMBRYANTHEMUM CRYSTALLINUM. *Ice-plant.* A biennial plant, growing spontaneously in the South of Europe, and cultivated as a curiosity in colder countries, by the aid of artificial warmth. The stem and under surface of the leaves are covered with crystalline drops, which give the plant the appearance of being coated with ice. The herb is without smell, and has a somewhat saline nauseous taste. It is considered demulcent and diuretic, and has been highly lauded as a remedy in various complaints, especially in those affecting the mucous membrane of the lungs and urinary passages. It has also been used in dropsy. The expressed juice is the form in which the remedy has been generally employed.

MOMORDICA BALSAMINA. *Balsam apple. Balsamina.* An annual climbing plant, a native of the East Indies, but cultivated in our gardens for the sake of the fruit. This is ovate, attenuated towards each extremity, angular, warty, not unlike a cucumber in appearance, of a lively red or orange-yellow colour, easily falling when touched, and spontaneously separating into several pieces. It was formerly highly esteemed as a vulnerary, and is still in use among the common people. A liniment formed by infusing the fruit, deprived of its seeds, in olive or almond oil, is applied to chapped hands, burns, old sores, piles, prolapsus ani, &c.; and the fruit itself is sometimes mashed and used in the form of poultice. According to M. Descourtlitz, it is poisonous when taken internally, having proved fatal to a dog in the quantity of two or three drachms; and an extract prepared from it is said to be useful in dropsy, in the dose of from six to fifteen grains.

MURIATIC ETHER. *Æther Muriaticus.* This ether was discovered by Rouelle, but first obtained in sufficient quantities to examine its properties by Basse. It may be procured by several processes, but the following is the best. Distil a mixture of equal measures of concentrated muriatic acid and alcohol, and receive the product, by means of a curved glass tube, in a tubulated bottle, half filled with water at a temperature between 70° and 80°, and connected by means of a second tube with another bottle, loosely corked, and surrounded by a mixture of common salt with snow or pounded ice. The ether which comes over into the first bottle, is mixed with alcohol and acid, which are retained by the water, while the pure ether passes forward, and is condensed in the refrigerated bottle. This ether must be kept in strong bottles, well secured with ground stoppers covered with leather. Before being opened, the bottle should be cooled down to the freezing point.

Muriatic ether is colourless, has a strong, slightly saccharine, alliaceous taste, and a penetrating, ethereal, alliaceous smell. Its sp. gr. at the temperatare of 41°, is 0.774. It is extremely volatile, entering into ebullition at 54°, so that in summer it may be collected, in the gaseous state, in bell-glasses over water. Its density in the state of vapour is 2.22. When kindled as issuing from a fine orifice, it burns with an emerald-green flame without smoke, diffusing a strong odour of muriatic acid; but when set on fire in quantities, it burns with a greenish-yellow smoky flame. Water dissolves one-fiftieth of its weight of this ether, and acquires a sweetish, ethereal taste, and alcohol unites with it in all proportions. These solutions are not precipitated by nitrate of silver, showing that the muriatic acid present is in a peculiar state of combination. Like sulphuric and nitric ether, it dissolves sulphur and phosphorus, the fat and volatile oils, and many other substances. It consists of one equiv. of muriatic acid 36.42, and one of etherine 28.48 = 64.90; or in volumes, of two volumes of the acid, and one volume of the vapour of etherine, condensed into two volumes.

Muriatic ether, like the other substances of this class, is a diffusible stimulant, but owing to its extreme volatility, cannot be kept in the shops. It may, however, be preserved in a cool cellar, the temperature of which does not rise above 45° or 50°, being well secured in bottles, which should be placed reversed. When used in medicine, it is generally mixed with an equal bulk of alcohol, when it is called *alcoholic muriatic ether.* The dose is from five to thirty drops, given in sweetened water, or other convenient vehicle.

MUSHROOMS. *Fungi.* Bot. This extensive family of cryptogamous plants is interesting to the physician, from the consideration, that, while some of them are very largely consumed as food in different parts of the world, others are deleterious in their nature, and capable, when eaten, of producing poisonous effects. Their substance is made up of a cellular tissue, which is usually of that soft consistence denominated fungous, but is sometimes corky, ligneous, or even gelatinous. Many of them have an agreeable odour and taste, while others are unpleasant or offensive both to the nostrils and palate. According to Braconnot, most of them contain, among other substances, a peculiar principle denominated *fungin*, a peculiar acid called *fungic acid* usually combined with potassa, and a peculiar saccharine matter less sweet than the other varieties of sugar, less soluble in alcohol and water than that of the cane, and distinguished by some writers as the *sugar of mushrooms. Fungin* constitutes the basis of these vegetables, and is the principle upon which their nutritive properties chiefly depend. It is the fleshy substance which remains when they are treated with boiling water holding a little alkali in solution. It is whitish, soft, and insipid; inflammable; insoluble in water, alcohol, ether, weak sulphuric acid, and weak solutions of potassa and soda; soluble in heated muriatic acid; decomposed by nitric acid, and by concentrated alkaline solutions; and decomposed by destructive distillation into substances resembling those which result from the distillation of animal matters.

It is highly important for those who employ mushrooms as food, to be able to distinguish those which are wholesome from the poisonous. The following general rules are given by M. Richard in the Dictionnaire des Drogues. Those should be rejected which have a narcotic or fetid odour, or an acrid, bitter, or very acid taste; which occasion a sense of constriction in the throat when swallowed; which are very soft, liquifying, changing colour, and assuming a bluish tint upon being bruised; which exude a milky, acrid, and styptic juice; which grow in very moist places, and upon putrefying substances; in fine, all such as have a coriaceous, ligneous, or corky consistence. The last, however, are injurious in consequence rather of their indigestible than of their poisonous nature. Even mushrooms which are usually edible, may prove poisonous, if collected too late, or in places which are too moist. It is said, moreover, that the poisonous species sometimes become innocent when they grow under favorable circumstances; and that the most noxious may be rendered edible by boiling them in water acidulated with vinegar. Immense quantities of mushrooms are eaten in France, Germany, Italy, and other parts of continental Europe: and it is asserted that they constitute the chief food of the people in certain provinces.

The symptoms produced by the poisonous mushrooms, are anxiety, nausea, faintness, vomiting, and if they are not rejected from the stomach, somnolence, stupor, small and intermittent pulse, tension of the abdomen, cold extremities, livid skin, and death in thirty-six or forty-eight hours. Sometimes violent pains in the stomach and bowels are experienced; and occasionally severe vomiting and purging occur and save the patient. The remedies are emetics, if the physician is called in time, accompanied with the free use of warm drinks, and followed by cathartics. After the evacuation of the alimentary canal, demulcent and nutritive beverages should be given, and the strength of the patient sustained by mild tonics or stimulants. Ether is particularly recommended. (*Merat* and *De Lens.*)

Some of the poisonous species have been used as medicines; but in this country they are never employed; and too little seems to be precisely known of their modes of action, and their qualities, even in the same species, vary too much, according to the circumstances of their growth and situation, to justify their introduction into the Materia Medica, without further investigation.

MUSK, ARTIFICIAL. *Moschus Factitius.* This is prepared by adding, drop by drop, three parts of fuming nitric acid to one of *unrectified* oil of amber. The acid is decomposed, and the oil converted into an acid resin, which must be kneaded under pure water, until all excess of acid is removed. The substance which remains is the artificial musk, and is of a yellowish-brown colour, viscid, and of an odour which recalls that of musk. It reddens litmus, dissolves sparingly in water, and more freely in alcohol. According to Setterberg, it contains three resins, two of which are soluble in boiling oil of turpentine; the third, insoluble. One of the soluble resins is obtained upon the cooling of the oil when it separates; the other by evaporating the cold oil from which the first has precipitated. (*Berzelius. Traité de Chim.* vi. 714.)

Dr. S. W. Williams, in a paper contained in the Boston Medical and Surgical Journal, gives the following formula for the preparation of artificial musk:—Add gradually, drop by drop, *three drachms and a half* of concentrated nitric acid to *a drachm* of *rectified* oil of amber, contained in a glass tumbler, or very large wineglass. The mixture grows hot, and emits offensive fumes which the operator must avoid. When the ordinary nitric acid is employed, which is not of full strength, the reaction must be assisted by heat; in which case Dr. Williams recommends that the vessel containing the mixed ingredients be placed in a plate before the fire, they being, meanwhile, continually stirred with a glass rod. The reaction is sometimes so violent as to eject part of the contents from the glass. After the mixture has remained at rest for twenty-four hours, it acquires a resinous appearance, and divides into two portions, an acid liquid below, and a yellow resin above, resembling musk in smell. This being thoroughly washed, first with cold and then with hot water, until all traces of acid are removed, is the artificial musk. (*Amer. Journ. of Pharm.* viii. 14. *April*, 1836.)

Artificial musk is an antispasmodic and nervine, and possesses the general therapeutic properties of the natural substance, though in a weaker degree. It is praised by Dr. Williams, from his personal experience, in the treatment of hooping cough, typhoid states of fever, and nervous diseases generally. When combined with water of ammonia, compound spirit of lavender, or laudanum, he has found no remedy so efficient in the sinking faintness, occurring in the last stages of pulmonary consumption. The average dose for an adult is ten grains; for a child of two years old from half a grain to a grain, repeated, in each case, every two or three hours. It may be prepared as the musk mixture, or with almonds in the form of emulsion. According to Berzelius, the tincture is formed by dissolving *a drachm* of artificial musk in *an ounce* of alcohol, equivalent to *ten fluidrachms* of the sp. gr. of 0.835. Of this the dose for an adult is a teaspoonful. The tincture recommended in the American Journal of Pharmacy (a drachm of the musk to four ounces of alcohol) is altogether too spirituous. Though artificial musk is not equal in power to the natural substance when genuine; yet it is in all probability superior to the adulterated article, so frequently sold under the name of musk. On this account, as well as in view of its comparative cheapness, it forms a useful substitute for musk, applicable to several forms of disease.

MYROBALANS. *Myrobalani.* These are the fruits of various East India trees, particularly of different species of Terminalia. They are noticed here partly on account of their ancient reputation, partly because they are still occasionally to be found in the shops, though seldom, if ever, used in medicine. Five varieties are distinguished by authors. 1. *Myrobalani belliricæ.* These are obtained from the *Terminalia Bellirica.* They are roundish or ovate, from the size of a hazelnut to that of a walnut, of a grayish-brown colour, smooth, marked with five longitudinal ribs, and sometimes furnished with a short thick footstalk. They consist of an exterior, thin, firm, resinous, brown, fleshy portion, and an interior kernel, which is light brown, inodorous, and of a bitterish very astringent taste. 2. *Myrobalani chebulæ.* This variety is produced by the *Terminalia Chebula.* The fruit is oblong, pointed at each extremity, from fifteen to eighteen lines in length, of a dark brown colour, smooth and shining, with five longitudinal wrinkles, but without footstalks. In their internal arrangement and taste, they resemble the preceding. 3. *Myrobalani citrinæ*, vel *flavæ.* These are from a variety of the same tree which affords the last mentioned myrobalans, from which they differ only in being somewhat smaller, of a light brown or yellowish colour, and of a taste rather more bitter. They have been sometimes sold in the shops in Philadelphia under the name of *white galls*, to which, however, they bear no other resemblance than in taste. 4. *Myrobalani Indicæ*, vel *nigræ.* These are thought to be the unripe fruit of the *Terminalia Chebula*, or *T. Bellirica.* They are ovate oblong, from four to eight lines long, and from two to three lines thick, of a blackish colour, wrinkled longitudinally, and presenting, when broken, a thick, brown mass, without kernel, but with a small cavity in the centre. They are sourish and very astringent. 5. *Myrobalani emblicæ.* This variety is wholly different from the preceding, and derived from a plant having no affinity to the Terminaliæ—namely, the *Phyllanthus Emblica* of Linnæus. It is often in segments, as kept in the shops. When the fruit is entire, it is blackish, spherical, depressed, of the size of a cherry, presenting six obtuse ribs with as many deep furrows, and separating into six valves, with a strongly astringent and acidulous taste.

These fruits were in high repute with the Arabians, and were long employed by European practitioners as primarily laxative, and secondarily astringent, in various complaints, particularly diarrhœa and dysentery. Their dose was from two drachms to an ounce. They are not now employed as medicines. We have been told that they have sometimes been used as a substitute for galls in the preparation of inkpowder.

NAPLES YELLOW. A yellow pigment prepared by calcining a mixture of lead, common sulphuret of antimony, dried alum, and muriate of ammonia, or a mixture of carbonate of lead, *diaphoretic antimony*, (a compound of peroxide of antimony and potassa, made by deflagrating one part of sulphuret of antimony with three of nitre,) dried alum, and muriate of ammonia. (*Gray.*)

NARCISSUS PSEUDO-NARCISSUS. *Daffodil.* This well known bulbous plant is a native of Europe, but is very common in the gardens of this country, where it attracts attention by the early appearance of its conspicuous yellow flowers. Both the bulb and flowers have been used in medicine. The latter have a feeble peculiar odour, and both have a bitter mucilaginous taste. They are emetic, though uncertain in their operation. It is probable that the flowers of the wild plant are more powerful than those of the cultivated. They may be given dried and powdered, or in the form of extract. The dose of the powder, to produce an emetic effect, varies, according to the statements of different physicians, from a scruple to two drachms; while the extract is said to vomit in the dose of two or three grains. It is conjectured that the emetic property is developed by the agency of water. The bulb is most powerful in the recent state, and, within our own knowledge, is occasionally used as an emetic in domestic practice in this country. When dried and powdered, it has been given in the dose of thirty-six grains without vomiting. The flowers are said also to possess antispasmodic powers, and have been used in France, with supposed advantage, in hooping-cough, epilepsy, and other convulsive affections. It is probable, however, that they operated in these cases by their nauseating or emetic property. They have, moreover, been advantageously employed in diarrhœa, dysentery, and intermittent fever. Other species of Narcissus are said to possess the same properties, though they have not been so much used.

NARD. *Spikenard.* Several aromatic roots were known to the ancients under the name of *nardus*, distinguished, according to their origin or place of growth, by the names of *nardus Indica*, *nardus Celtica*, *nardus montana*, &c. They are supposed to have been derived from different species of *Valeriana*. Thus the nardus Indica is referred to the *V. Jatamensi* of Bengal, the nardus Celtica to the *V. Celtica*, inhabiting the Alps, Apennines, &c., and the nardus montana to the *V. tuberosa*, which grows in the mountains of the South of Europe. The Indian nard, or spikenard, sometimes also called Syrian nard, is still occasionally to be found in the shops. It is a small, delicate root, from one to three inches long, beset with a tuft of soft, light-brown, slender fibres, of an agreeable odour, and a bitter, aromatic taste. It was formerly very highly esteemed as a medicine, but is now almost out of use. Its properties are analogous to those of the officinal valerian.

NASTURTIUM OFFICINALE. R. Brown. *Sisymbrium Nasturtium*, Linn. *Water-cress.* A small, perennial, herbaceous, succulent plant, growing in springs, rivulets, and ponds, in North America, Europe, and some parts of Asia. The fresh herb has a quick penetrating odour, especially when rubbed, and a bitterish, pungent taste, but loses both when dried. In sensible and medical properties it bears some resemblance to scurvy-grass, though milder, and on this account is preferred for the table. It is thought to be useful in scorbutic affections, and visceral obstructions. The expressed juice is sometimes given in the dose of one or two ounces; but the herb is more frequently used in the form of a salad. Other species of Nasturtium, as the *N. palustre* or *marsh water-cress*, and the *N. amphibium* or *water-radish*, grow in similar situations with the *N. officinale*, and possess similar virtues.

NEPETA CATARIA. *Catmint. Catnep.* This is a well-known perennial herbaceous plant, very common in the United States, but supposed by some to have been introduced from Europe. It is found most abundantly along the roadsides, and may be distinguished by its quadrangular somewhat hoary stem, from one to three feet high, its opposite, petiolate, cordate, dentate, pubescent leaves, green above, and whitish on their under surface, and its whitish or slightly purple, labiate didynamous flowers, which are terminal and axillary, verticillate, somewhat in the form of a spike, and appear in July and August. The herbaceous part is used. It has a strong, peculiar, rather disagreeable odour, and a pungent, aromatic, bitterish, camphorous taste. It yields its virtues to water. Cats are said to be very fond of it. In its operation upon the system it is tonic and excitant, bearing considerable resemblance to the mints, and other labiate plants. It is employed in domestic practice, in the form of infusion, as a remedy in amenorrhœa, hysteria, chlorosis, &c.; but is scarcely known in regular practice. Some of the older medical writers speak favourably of its powers. Two drachms of the dried herb may be given as a dose in infusion.

NIGELLA SATIVA. *Nutmeg flower. Small fennel-flower.* A small annual plant, growing wild in Syria and the South of Europe, and cultivated in various parts of the world. The seeds, which are sometimes kept in the shops under the name of *semen nigellæ*, are ovate, somewhat compressed, about a line long and half as broad, usually three-cornered, with two sides flat and one convex, black or brown externally, white and oleaginous within, of a strong, agreeable, aromatic odour, like that of nutmegs, and a spicy pungent taste. Their chief constituents are a volatile and fixed oil. They are analogous to the other aromatics in properties, and though not at present used in medicine, have been employed in some countries from the remotest times as a condiment.

NITRATE OF SODA. *Cubic Nitre.* This salt may be formed by treating carbonate of soda with nitric acid. It exists naturally, in inexhaustible quantities, in the desert of Atacama in Peru, where it forms a bed of variable thickness, covered with clay, of one hundred and fifty miles in extent. Considerable quantities have been extracted for the purposes of commerce. Occasionally a cargo is brought to the United States.

Nitrate of soda, when pure, is a white salt, crystallizing in rhomboidal prisms, and having a sharp, cooling, and bitter taste. It attracts moisture readily from the air, and dissolves in about twice its weight of water at 60°. As it usually comes from Peru it is in dirty-white saline lumps, rather soft and friable, and damp on the surface. It is cheaper than nitre, for which salt it may be substituted in the manufacture of sulphuric acid, and in the preparation of nitric acid, chrome yellow, &c.

As nitrate of soda has been imposed upon our merchants for nitre, it may be useful to mention that the former salt may be distinguished by its giving rise to an orange-yellow flame when thrown on burning coals, and by the rhomboidal shape of its crystals; those of nitre being long six-sided prisms. (See page 516.)

NYMPHÆA ODORATA. *Sweet-scented Water-lily.* An indigenous herbaceous perennial, growing in most parts of the United States, in fresh-water ponds and the borders of streams, and distinguished by the beauty and delicious odour of its large, white, many-petaled flowers. Its root is, when fresh, large and fleshy, but becomes light, spongy, and friable by drying. It is very astringent and bitter; and, according to Dr. Bigelow, contains much tannin and gallic acid. It is sometimes employed, in the form of poultice, as a discutient application. The root of the *Nymphæa alba*, or European *white water lily*, was esteemed aphrodisiac by the ancients; but has long lost this reputation. Like that of the American plant, it is bitter and styptic, and may have been useful by its astringency in some cases of leucorrhœa, gonorrhœa, dysentery, &c., in which it was formerly employed for its reputed sedative virtues.

OCHRES. These are native mixtures of argillaceous or calcareous earth and oxide of iron, employed in painting. They are prepared for use by agitating them with water, decanting the turbid liquor after the coarser particles have subsided, then allowing it to rest in order that the finer parts may be deposited, and lastly drying the sediment which forms. The colour of the ochres varies with the state of oxidation of the iron, and with the proportion which it bears to the other ingredients, and is sometimes artificially modified by the agency of heat. Several varieties are kept in our shops, under different names, according to their colour, or place of origin. Such are the *brown ochre*, the *yellow ochre*, the *red ochre*, the *Roman ochre* of a brownish-yellow changing by heat to a purple red, the *Oxford ochre* of a brownish-yellow colour less deep than the Roman, and the *French ochre* which is yellow. The *Indian red* from the Persian Gulf, and *Spanish brown*, may also be ranked in this class of pigments. Sometimes ochres come in a powdery state, and sometimes in hard masses; in the latter state they are called *stone ochres.*

OCIMUM BASILICUM. *Basil.* An annual plant, a native of India and Persia, and cultivated in Europe and in this country in gardens. The whole plant has a strong, peculiar, agreeable, aromatic odour, which is improved by drying. The taste is aromatic, and somewhat cooling and saline. Basil has the ordinary properties of the aromatic plants, and is in some places considerably used as a condiment. The seeds are said by Ainslie to be used in India, in the form of infusion, as a remedy in gonorrhœa and nephritic affections.

ŒNANTHE CROCATA. *Hemlock Water-dropwort.* A perennial, umbelliferous, aquatic, European plant, exceedingly poisonous both to men and inferior animals. The root, which has a sweetish not unpleasant taste, is sometimes eaten by mistake for other roots, with the most dangerous effects; and numerous instances of fatal results are on record. The symptoms produced are such as attend irritation or inflammation of the stomach, united with great cerebral disturbance. Externally applied, the root produces redness and irritation of the skin, with an eruptive affection. It is said to be sometimes used empyrically as a local remedy in piles; and a case is recorded, in which an obstinate leprosy was cured by the continued use of the juice of the plant. Other species of *Œnanthe* are poisonous, and the whole genus should be regarded among the suspected plants. We have two or three indigenous species. The proper remedies in cases of poisoning from these plants, are emetics, followed, after the stomach has been thoroughly evacuated, by mucilaginous and other demulcent drinks.

ŒNOTHERA BIENNIS. *Tree Primrose.* A biennial indigenous plant, growing in fields and along fences, from Canada to Carolina. It is from two to five feet high, with a rough stem, alternate, ovate-lanceolate leaves, and fine yellow flowers, which make their appearance in July and August. Schoepf states that it is esteemed useful as a vulnerary. Dr. R. E. Griffith, of Philadelphia, has found a strong decoction of the small branches, with the leaves and cortical part of the stem and larger branches, very beneficial in eruptive complaints, especially tetter. He applies the decoction several times a day to the affected part. He thinks the virtues of the plant reside in the cortical part, which has a mucilaginous taste, and leaves a slight sensation of acrimony in the fauces. (*Journ. of the Phil. Col. of Pharm.* iv. 292.)

OIL OF EUPHORBIA. A fixed oil, obtained from the seeds of the *Euphorbia Lathyris*, a biennial plant growing wild in this country, though believed to have been introduced from Europe, where it is indigenous. It is often found near gardens and in cultivated fields, and is generally called *mole-plant*, under the impression that moles avoid the grounds where it grows. (*Pursh.*) It is the *Caper plant* of England. (*Loudon's Encyc. of Plants.*) Like the other species of euphorbia, it contains a milky juice, which is extremely acrid; and the whole plant possesses the properties of a drastic purge; but the oil of the seeds is the only part used in regular practice. This may be extracted by expression, or by the agency of alcohol or of ether. In the first case, the bruised seeds are pressed in a canvass or linen bag, and the oil which escapes is purified by decanting it from the whitish flocculent matter which it deposites upon standing, and by subsequent filtration. By the latter process, the bruised seeds are digested in alcohol or macerated in ether, and the oil is obtained by filtering and evaporating the solution. According to Soubeiran, however, the oil obtained by these different processes is by no means identical. That procured by expression is probably the purest.

Oil of euphorbia is colourless, inodorous, and, when recent, nearly insipid; but it speedily becomes rancid, and acquires a dangerous acrimony. Soubeiran has ascertained, that it has a complex composition, containing, besides the pure oil, four distinct proximate principles. (*Journ. de Pharm.* xxi. 259.) From 40 to 44 parts are obtained by expression from 100 of the seeds.

This oil is a powerful purge, operating with much activity in a dose varying from five to ten drops. It has within a few years been much used by some Italian and French physicians, who have not found it to produce inconvenient irritation of the stomach or bowels. Its want of taste, and the smallness of the dose, recommend it especially in the cases of infants. It is said to be less acrid and irritating than the croton oil, over which it also has the advantage of greater cheapness. Some trials which have been made with it on this side of the Atlantic have not tended to confirm these favourable reports. It was found uncertain in its cathartic effect, and very liable to vomit. (*Scattergood, Journ. of the Phil. Col. of Pharm.* iv. 124.) It may be given in pill with the crumb of bread, or in emulsion.

OIL OF JASMINE. This oil is obtained from the flowers of the *Jasminum officinale*, or *common white jasmine*, and from those also of the *J. Sambac* and *J. grandiflorum.* Alternate layers of the fresh flowers, and of cotton saturated with the oil of ben (expressed oil of *Hyperanthera Moringa*), or perhaps other fixed oil, are exposed in a covered vessel to the warmth of the sun, the flowers being occasionally renewed, till the oil becomes impregnated with their odour, when it is separated from the cotton by pressure. This method is necessary, as the flowers do not yield their aroma by distillation. The oil of jasmine is used only as a perfume.

ORANGE RED. *Orange Mineral. Sandix.* Red oxide of lead, prepared by calcining carbonate of lead. It is of a brighter colour than *minium*, and is used as a pigment.

OROBANCHE VIRGINIANA. *Epifagus Americanus*, Nuttall. *Beech-drops. Cancer-root.* A parasitic, fleshy plant, with a tuberous, scaly root, and a smooth stem, branched from the base, from twelve to eighteen inches high, furnished with small ovate scales, of a yellowish or purplish colour, and wholly destitute of verdure. It is found in all parts of North America, growing upon the roots of the beech tree, from which it obtained its popular name. It is in some places very abundant. The plant has a bitter, nauseous, astringent taste, which is said to be diminished by drying. It has been given internally in bowel affections; but its credit depends mainly upon the idea that it is useful in obstinate ulcers of a cancerous character, to which it is directly applied in the state of powder. The late Professor Barton, conjectured that it was an ingredient of a secret remedy, at one time famous as *Martin's cancer powder*, of which, however, the most active constituent was arsenious acid.

Other species of Orobanche, growing in America and Europe, have been employed. They are all parasitic, fleshy plants, without verdure, and of a bitter, nauseous taste. In Europe they are called *broom-rape.* The *O. Americana* and *O. uniflora*, of this country, are said to be used for the same purposes as the species above noticed, and like it are called *cancer-root.*

ORPIMENT. *King's Yellow.* A native sulphuret of arsenic, consisting of one equiv. of metal 37.7, and one equiv. and a half of sulphur 24.15=61.85. It is in masses of a brilliant lemon-yellow colour, composed of flexible laminæ, and slightly translucent. It exists in various parts of the world, but is obtained for use from Persia and China. (*Guibourt.*) It is sometimes mixed with realgar, which gives it a reddish or orange hue. A similar sulphuret may be made artificially by passing sulphuretted hydrogen through a solution of arsenious acid in muriatic acid. There is reason to believe that neither the native sulphuret, nor the artificial, when prepared in the manner just mentioned and well washed, is poisonous; at least in a degree at all comparable to other arsenical compounds.

Artificial orpiment is prepared for use by fusing together equal parts of arsenious acid and sulphur. (*Turner.*) In Germany, according to Guibourt, it is prepared by subliming a mixture of these two substances, In this case, however, it retains a large portion of the acid undecomposed, and is therefore highly poisonous. Guibourt found a specimen which he examined, to contain 96 per cent. of arsenious acid, and only 6 per cent. of the sulphuret of arsenic.

Orpiment is used chiefly as a pigment.

ORYZA SATIVA. *Rice.* This is an annual plant, originally, perhaps, derived from the

East Indies, but now cultivated in all parts of the globe where the climate and soil are adapted to its growth. The rice of commerce consists of the seeds of the plant deprived of their husk. Carolina rice was found by Braconnot to contain 85.07 per cent. of starch, 3.60 of gluten, 0.71 of gum, 0.29 of uncrystallizable sugar, 0.13 of fixed oil, 4.80 of vegetable fibre, 5.00 of water, and 0.40 of saline substances. This grain is highly nutritious, and of easy digestion, and constitutes the almost exclusive diet of whole nations. It is admirably adapted to cases of weak bowels, in which there is a strong tendency to diarrhœa. Care, however, should be taken, that it be boiled till it becomes soft. A decoction of rice, usually called *rice-water*, is a good nutritive drink in fevers and inflammatory affections of the bowels, lungs, and kidneys.

OXALIC ACID. *Acidum Oxalicum.* This acid is found both in animals and vegetables. It is generated occasionally in consequence of a diseased action of the kidneys, and deposited in the bladder as an oxalate of lime, forming a peculiar concretion, called from its appearance the mulberry calculus. In vegetables, it occurs in a free state in the bristles of the chick-pea, (*Cicer arietinum*), combined with potassa as a supersalt in the *Rumex acetosa* or common sorrel, and the *Oxalis acetosella* or wood sorrel, and united with lime in several species of lichen, and in the roots of rhubarb, valerian, and of several other plants. It is from the generic appellation *Oxalis*, that it takes its name.

Preparation. This acid may be prepared, by proper management, from the juice of the wood sorrel. The first step is to obtain the binoxalate of potassa in crystals, by a careful evaporation of the juice of the plant. The excess of acid is then neutralized with carbonate of potassa, and the neutral oxalate is decomposed by acetate of lead. In consequence of a double decomposition, a precipitate of oxalate of lead is obtained. This is to be well washed and dried, and decomposed by means of one-third of its weight of strong sulphuric acid, previously diluted with ten times its weight of water. An insoluble sulphate of lead is formed, and the oxalic acid, being liberated, may be made to crystallize by evaporation. The mother waters, by further evaporation, will furnish fresh portions of crystals, until quite exhausted. By this process a very pure acid may be obtained.

The usual process for obtaining oxalic acid consists in decomposing sugar by nitric acid. Four parts of sugar are acted upon by twenty-four parts of nitric acid of the sp. gr. 1.220, and the mixture heated so long as any nitric oxide is disengaged. A part of the carbon of the sugar is converted into carbonic acid by oxygen derived from the nitric acid, which is thereby partially converted into nitric oxide. The undecomposed nitric acid, reacting on the remaining elements of the sugar, generates oxalic and malic acids, the former of which crystallizes as the materials cool, while the latter remains in solution. The crystals being removed, a fresh crop may be obtained by further evaporation. The thick mother water which now remains is a mixture of malic, nitric, and oxalic acids; and by treatment with six times its weight of nitric acid, the greater part of the malic acid will be converted into oxalic acid. The new crop of crystals, however, will have a yellow colour, and contain a portion of nitric acid, the greater part of which may be got rid of by allowing them to effloresce in a warm place.

Many substances besides sugar yield oxalic, by the action of nitric acid; as for example, starch, gum, wool, hair, silk, and many vegetable acids. In every case in which it is thus generated, the proportional excess of oxygen which it contains, compared with every other organic compound, is furnished by the nitric acid. Organic substances yield oxalic acid also when heated with potassa. Thus shavings of wood, if mixed with a solution of caustic potassa, and exposed to a heat considerably higher than 212°, will be partially decomposed and converted into oxalic acid, which then combines with the alkali. This process constitutes, perhaps, the cheapest method of obtaining oxalic acid.

Properties. Oxalic acid is a colourless crystallized solid, possessing considerable volatility, and a strong sour taste. Its crystals have the shape of slender, flattened, four or six-sided prisms, with two-sided summits; and when exposed to a very dry atmosphere, undergo a slight efflorescence. It dissolves in about nine times its weight of cold, and in its own weight of boiling water. The solution of the crystals takes place with slight crepitation. It dissolves also, but not to the same extent, in alcohol. The presence of nitric acid renders it more soluble in water. It combines with salifiable bases, and forms salts called oxalates. The most interesting of these are the three oxalates of potassa, severally called oxalate, binoxalate, and quadroxalate, and the oxalate of lime. The binoxalate of potassa is the *salt of sorrel*, sometimes absurdly called in the shops, the *essential salt of lemons*. It is employed for removing iron moulds from linen, and acts by its excess of acid forming a soluble salt with the peroxide of iron constituting the stain.

This acid has a very strong affinity for lime, and forms with it an insoluble precipitate, consisting of oxalate of lime, whenever the acid and earth are brought into contact. Hence, oxalic acid and its soluble combinations are the best tests we possess for lime; and conversely, a soluble salt of lime, for oxalic acid. When lime is searched for, the oxalate usually employed is the oxalate of ammonia, as being the most convenient. So strong is the mutual attraction between this acid and lime, that the former takes the latter, even from sulphuric acid. Hence, the addition of a soluble oxalate disturbs the transparency of a solution of sulphate of lime.

Oxalic acid is distinguished from all other acids, by the form of its crystals, and by its solution yielding a precipitate with lime-water, insoluble in an excess of the acid.

Composition. Oxalic acid consists of two equivalents of carbon 12.24, and three of oxygen 24=36.24. When crystallized, three equiv. of water 27, must be added, making the equiv. of the crystals 63.24. Two equivalents of this water may be driven off by a regulated heat, by which the acid is made to effloresce; but the third cannot be expelled without destroying the acid itself. Accordingly, as in the case of nitric acid, we have no knowledge of anhydrous oxalic acid in an uncombined state.

From the composition of oxalic acid, as above given, it is plain that this acid corresponds in composition to carbonic acid and oxide, taken together, and is, therefore, intermediate, in the quantity of oxygen which it contains, between this acid and oxide. Notwithstanding it contains less oxygen than carbonic acid, it is incomparably a stronger acid, which circumstance may be accounted for by supposing some peculiarity in the mode in which its constituents are combined. The composition of the acid not only corresponds with the united constituents of carbonic acid and oxide, but there is reason to believe that these two compounds are actually its proximate constituents; for if treated with strong sulphuric acid, the whole of the water will be abstracted, and the elements of the dry oxalic acid will be instantly resolved into equal volumes of carbonic acid and oxide. Oxalic acid seems, therefore, to require one equivalent of water as a bond of union between its elements, without which they arrange themselves in a new binary order.

Oxalic acid combines with salifiable bases in two principal ways. Sometimes it drops its essential equivalent of water, which at other times it retains. Thus the oxalate of lead is a compound of the dry acid and the protoxide of lead; while the oxalate of lime retains the one equivalent of water. Dulong has suggested that the proto-hydrated acid might be viewed as a hydracid, consisting of two equiv. of carbonic acid and one equiv. of hydrogen, and that where the acid appears to lose one equiv. of water, it is made up between the hydrogen of this acid and the oxygen of the base. According to this view, when oxalic acid combines with protoxide of lead, the hydrogen of the acid unites with the oxygen of the protoxide, forming water which is dissipated, while the carbonic acid combines with the metallic lead. For oxalates susceptible of this hypothetical view, Dulong has proposed the name of *carbonides.* Whatever theory we may adopt, it is certain that, in oxalate of lead and similarly constituted oxalates, if we suppose the oxygen of the protoxide transferred to the elements of the oxalic acid, we shall have what corresponds with two equiv. of carbonic acid, and one of metal; but as we know of no instance in which carbonic acid combines directly with a metal, it seems unlikely that Dulong's view will prove correct.

Medical and Toxicological Properties. According to Dr. A. T. Thomson, oxalic acid in *small* doses, largely diluted with water and sweetened to the taste, forms an agreeable, cooling beverage, which may be used in febrile diseases as a substitute for lemonade. Notwithstanding the safety of its employment in this way, it is a virulent poison, producing death with great rapidity and certainty. Instances are on record of its proving fatal in ten minutes, and few survive the effects of a poisonous dose beyond an hour. As this acid is generally kept in the shops, and not a few instances are on record of its fatal effects, when taken by design, or by mistake for Epsom salt, we shall feel ourselves justifiable in being somewhat full on its toxicological relations.

Oxalic acid was first noticed as a poison by Mr. Royston in 1814; since which time it has been principally investigated in this relation by Dr. A. T. Thomson of London, Dr. Percy of Lausanne, Dr. Coindet of Geneva, and Dr. Christison of Edinburgh. Since its properties of certainty and rapidity as a poison have been more generally known, its employment for committing suicide has become more frequent.

From the general resemblance which the crystallized oxalic acid bears to Epsom salt, many fatal mistakes have occurred since the acid has become so extensively an article of commerce, in consequence of its being sold for that saline purgative. Nothing, however, can be easier than to distinguish them; for upon tasting a minute portion of the acid, which may be done with perfect safety, it will be found strongly sour, whereas the salt in question is bitter. Unfortunately, however, in the instances of these fatal mistakes, no suspicions being awakened, the solution is swallowed with the greatest rapidity, and the mischief is done before the victim is aware of his danger.

Oxalic acid acts on the animal economy in two principal ways, according as its solution is concentrated or dilute. When concentrated, it causes exquisite pain, followed by violent efforts to vomit; then sudden dulness, langour, and great debility, and finally death without a struggle. When dilute, it acts in a totally different manner. Dissolved in twenty times its weight of water, it possesses no corrosive, and hardly any irritating power, and yet it operates as a deadly poison, causing death by acting indirectly on the brain, spinal marrow, and heart.

The morbid appearances caused by oxalic acid are various. In a dissection reported by Dr. Christison, the mucous coat of the throat and gullet had an appearance as if scalded, and that of the gullet could be easily scraped off. The inner part of the stomach was pultaceous, in many points black, in others red; and that of the intestines, similarly but less violently affected. In another case recorded by the same author, the whole villous coat of the stomach was either softened or removed, as well as the inner membrane of the œsophagus; so that the muscular coat was exposed, and this coat exhibited a dark gangrenous appearance, being much thickened, and highly injected. The stomach usually contains a dark fluid, resembling coffee-grounds, consisting chiefly of altered blood. In a few cases after death by this acid, no morbid appearances have been discovered.

In the treatment of poisoning by oxalic acid, the remedial measures must be employed with great promptitude. If the antidotes are not at hand and vomiting is not free, emetics will be proper. The stomach pump would be useful; but no delay in the application of other remedies is admissible, in anticipation of its use. Dr. Christison objects to the use of warm water to promote vomiting, from a fear that it would increase the danger by promoting the absorption of the poison; but it may be a question whether this evil, considering the incidental benefit of the water in promoting vomiting, is not less than that of the corrosion of the stomach, which copious dilution has a tendency to prevent. The proper antidote is magnesia or chalk, mixed with water; and as soon as either can be procured, it must be administered in large and frequently repeated doses. Chalk was first proposed for this purpose by Dr. A. T. Thomson, of London. These substances act by neutralizing the poison, forming with it either an insoluble oxalate of magnesia or of lime, both of which are inert. Alkalies as antidotes are inadmissible, as the soluble salts of this acid are likewise poisonous.

The best tests for the detection of oxalic acid in the contents of the stomach or in the vomited matter, in cases of suspected poisoning by this acid, are muriate of lime, sulphate of copper, and nitrate of silver. The first causes a white precipitate of oxalate of lime, known by its being soluble in nitric acid; the second, a bluish-white precipitate of oxalate of copper; and the third, a dense white precipitate of oxalate of silver, which, when dried and heated, becomes brown and detonates faintly. When the antidotes have been freely used during life, the poison will be in the state of oxalate either of lime or magnesia. Here the oxalate found is to be boiled with a solution of carbonate of potassa, whereby an oxalate of potassa will be generated; and this must then be examined by the re-agents above indicated.

OX-GALL. *Fel Bovinum.* The bile of the ox is a viscid fluid, of a green or greenish-yellow colour, a peculiar nauseous odour, and a bitter taste. According to Gmelin, it contains, besides water, 1. a volatile principle, having the odour of musk; 2. a peculiar fatty matter, originally found in biliary calculi, called *cholesterin*; 3. oleic acid; 4. margaric acid; 5. a new acid, called *cholic acid;* 6. a bitter resinous substance, called *biliary resin;* 7. a crystalline principle, called *taurin;* 8. *biliary sugar;* 9 a *colouring substance* upon which the characteristic colour of the bile depends; 10. a kind of extractive matter; 11. a substance analogous to vegetable gluten; 12. caseous matter; 13. salivary matter; 14. albumen; 15. mucus; 16. various saline substances. The resin and sugar, with the colouring matter, appear to be the characteristic constituents. Gmelin considers the *picromel* of Thenard as a mixture of the sugar of the bile with a portion of the resin which it renders soluble in water.

Bile was formerly highly valued as a remedy in numerous complaints, and was considered peculiarly applicable to cases attended with deficient biliary secretion. It is supposed to be tonic and laxative. It is prepared for use by evaporating it to the consistence of an extract. The dose is from five to ten grains. *Refined ox-gall*, much used by limners and painters, is prepared, according to Gray, in the following manner. Take of "fresh ox-gall one pint; boil, skim, add one ounce of alum, and keep it on the fire for some time; to another pint, add one ounce of common salt in the same manner; keep them bottled up for three months, then decant off the clear: mix them in an equal proportion; a thick yellow coagulum is immediately formed, leaving the refined gall clear and colourless."

PÆONIA OFFICINALIS. *Peony.* This well known plant is a native of Southern Europe, but is every where cultivated in the gardens for the beauty of its flowers. The root, flowers, and seed were formerly officinal. The *root* consists of a caudex about as thick as the thumb, which descends several inches into the ground, and sends off in all directions spindleshaped tubers that gradually taper into thread-like fibres, by which they hang together. It has a strong, peculiar, disagreeable odour, and a nauseous taste, which is at first sweetish, and afterwards bitter and somewhat acrid. The odour disappears or is much diminished by drying. Peony root was in very great repute among the ancients, who used it both as a charm and as a medicine in numerous complaints, particularly epilepsy. In modern times it has also been given in epilepsy and various nervous affections, but is at present seldom used. The dose of the fresh root is from two drachms to an ounce, boiled in a pint of water down to half a pint, which should be taken daily. It is said to be less active when dried. The expressed juice of the recent root is recommended in the dose of an ounce. It is milky, of a strong odour, and very disagreeable taste. The *flowers* are usually of a deep-red colour, though in some varieties of a light red, and even whitish. They have, when fresh, an odour similar to that of the root, but feebler, and an astringent, sweetish, herbaceous taste. When dry, they are inodorous. As a medicine they have little power, and are scarcely used. The *seeds* are roundish oval, about as large as a pea, externally smooth, shining, and nearly black, internally whitish, inodorous when dry, and of a mild oleaginous taste. By some authors they are said to be emetic and purgative, and by others are considered antispasmodic. They may be given in the same dose with the roots, but are not used in regular practice.

PAREIRA BRAVA. Under this name the root of a South American plant, said to be the *Cissampelos Pareira*, has been known in Europe since the year 1688, when it was introduced from Brazil. It comes in pieces from the thickness of the finger to that of the arm, two or more feet in length, cylindrical, sometimes contorted, forked, and covered with a thin, firmly adhering, smooth, brown bark. The inner part is ligneous, yellowish, very porous, marked by irregular concentric circles, inodorous, and of a sweetish, nauseous, bitter taste. It is said to be tonic, aperient, and diuretic; and has been recommended as a remedy in calculous affections, ulceration of the kidneys and bladder, leucorrhœa, dropsy, rheumatism, jaundice, and other complaints. The dose of the powder is half a drachm or a drachm. The root was also given in decoction. It is at present scarcely used.

PARIETARIA OFFICINALIS. *Wall Pellitory.* A perennial European herb, growing on old walls and heaps of rubbish. It is inodorous, has an herbaceous, somewhat rough and saline taste, and contains nitre derived from the walls where it flourishes. It is diuretic and refrigerant, and is said also, but without good reason, to be demulcent and emollient. The ancients employed it in various complaints, and it is still considerably used on the continent of Europe, especially in domestic practice. It is given in complaints of the urinary passages, dropsy, and febrile affections, usually in the form of decoction. The expressed juice is also used, and the fresh plant is applied in the shape of a cataplasm to painful tumours.

PATENT YELLOW. *Mineral Yellow.* A pigment, consisting of chloride combined with protoxide of lead. It is prepared by mixing common salt and litharge with a sufficient quantity of water, allowing the mixture to stand for some time, then washing out the liberated soda, and exposing the white residue to heat.

PHELLANDRIUM AQUATICUM, Linn. *Œnanthe Phellandrium*, Lamarck. *Fine-leaved Water-hemlock.* A biennial or perennial, umbelliferous, European water-plant, the fresh leaves of which are said to be injurious to cattle, producing a kind of paralysis when eaten. By drying, they lose their deleterious properties. The *seeds* have been used in Europe, to a considerable extent, in the treatment of disease. They are from a line to a line and a half in length, ovate-oblong, narrower above, somewhat compressed, marked with ten delicate ribs, and crowned with the remains of the calyx and with the erect or reverted styles. Their colour is yellowish-brown, their odour peculiar, strong, and disagreeable; their taste acrid and aromatic. Among their constituents is a volatile oil, upon which their aromatic flavour depends. By different writers they are described as aperient, diuretic, emmenagogue, expectorant, and sedative. They probably unite mild narcotic properties with the stimulant powers which are common to most of the aromatics, and may be directed, according to circumstances, to different secretory organs. In over doses they produce vertigo, intoxication, and other narcotic effects. The complaint in which they appear to have been used most successfully is consumption, probably of the catarrhal character. They have been given also in asthma, dyspepsia, intermittent fever, obstinate ulcers, &c. The dose of the seeds, to commence with, is five or six grains, so repeated as to amount to a drachm in twenty-four hours. They should be given in powder.

PHOSPHORUS. This elementary substance was discovered in 1669 by Brandt, an alchemist of Hamburg; and the process by which it was made, remained a secret until 1737. At first it was obtained from putrid urine, and was exceedingly scarce and costly; but in 1769, Gahn discovered it in bones, and shortly afterwards published a process by which it might be extracted from them; and his method has been followed, with but slight modifications, up to the present time. The mode of preparation is as follows. Calcined bones, which consist principally of phosphate of lime, are digested for twenty-four hours with two-thirds of their weight of strong sulphuric acid, previously diluted with twelve times its weight of water. The sulphuric acid detaches half the lime from the phosphoric acid, and precipitates as sulphate of lime; while a biphosphate of lime remains in solution. The mixture is then strained through a linen cloth to separate the sulphate of lime, and afterwards submitted to evaporation, which causes a fresh precipitation of sulphate, requiring to be separated by a new filtration. The filtered solution of biphosphate is evaporated to a syrupy consistence, and then thoroughly mixed with half its weight of powdered charcoal, so as to form a soft mass, which is dried by being heated to dull redness in an iron pot. The mass when cool is quickly transferred to a coated earthenware retort, furnished with an adopter of copper, bent downwards at right angles so as to enter a bottle with a large neck containing water, which should rise about two lines above the orifice of the adopter. The bottle is closed round the adopter by a cork, which is traversed by a small glass tube, to give exit to the gaseous products. The retort is heated in a furnace, furnished with a dome, in the most gradual manner, so as to occupy about four hours in bringing it to a red heat. Afterwards the heat is pushed vigorously, so long as any phosphorus drops into the water; and this takes place generally for from twenty-four to thirty hours. During this part of the process the excess of acid in the biphosphate is decomposed; its oxygen combining with the charcoal, and the liberated phosphorus distilling over. A quantity of the materials sufficient to fill a quart retort will yield about a pound of phosphorus.

Properties. Phosphorus is a semitransparent solid, without taste, but possessing an alliaceous smell. When perfectly pure it is colourless; but as usually prepared it is yellowish or reddish-yellow. It is flexible, sectile, and when cut exhibits a waxy lustre. It is insoluble in water, but dissolves sparingly in alcohol and the oils, and more freely in ether. Its sp. gr. is 1.77, and its equivalent number 15.71. It takes fire at 100°, melts at 105°, and boils at 550°, air being excluded. During its combustion, it combines with the oxygen of the air, and forms phosphoric acid. On account of its great inflammability it requires to be kept under water. When exposed to the air, it undergoes a slow combustion, emitting white vapours, which are luminous in the dark. It forms three acids with oxygen, the hypophosphorous, phosphorous, and phosphoric, and two compounds with hydrogen, phosphuretted hydrogen and subphosphuretted hydrogen. The only medicinal combinations containing phosphorus are phosphoric acid, and the phosphates of mercury, iron, lime, and soda. The three latter phosphates are officinal.

Medical Properties. Phosphorus, exhibited in small doses, acts as a powerful general stimulant; in large doses, as a violent irritant poison. Its action seems particularly directed to the kidneys and genital organs, producing diuresis, and excitation of the venereal appetite. The latter effect has been conclusively proved by the experiments of Alphonse Leroy, Chenevix, and Bertrand-Pelletier. From its peculiar physiological action, it is considered applicable as a remedy to diseases attended with extreme prostration of the vital powers. It has been recommended in dropsy, impotency, typhus fever, phthisis, marasmus, chlorosis, paralysis, gutta-serena, mania, &c. The best form for exhibition is an ethereal solution, as directed by the Paris Codex, under the title of *Æther Phosphoratus.* This solution contains about three grains of phosphorus to the ounce, and may be given in the dose of ten drops, repeated every two or four hours, according to circumstances, in a small portion of some bland drink. Magendie, in his formulary, published in Paris in 1835, recommends the solution of six grains of phosphorus in an ounce of rectified ether, agreeably to the formula of Bertrand-Pelletier. The solution is effected by cutting the phosphorus in small pieces, and agitating it with the ether, from time to time, for three or four days. Of this solution, he indicates ten drops as the dose; although it is twice as strong as that of the Paris Codex. It has been objected to the ethereal solution, that, upon the evaporation of the ether, the phosphorus is liable to be set free, and may inflame in the stomach. It is on this account that oil has been proposed as a solvent, according to the following formula of M. Lescot. Take of phosphorus *a drachm*, olive or almond oil, *an ounce and a half.* Cut the phosphorus into very small pieces, introduce them into a ground stoppered bottle, and add the oil. Let the mixture stand in a dark place for fifteen days; after which decant, and give the solution an aromatic flavour with the oil of bergamot. This solution is called *Aromatic Phosphoric Oil*, and must be kept in a dark place. It may be given to the extent of twenty-five or thirty drops in the twenty-four hours, mixed with some mucilaginous drink.

Great caution is necessary in the exhibition of phosphorus, and its effects should be closely watched. It ought never to be given in substance; as when thus administered, it is apt to produce violent irritation of the stomach. When taken in substance in a poisonous dose, two or three grains of tartar emetic should be given to dislodge it. If swallowed in the state of solution, then copious draughts of cold water containing magnesia in suspension would be proper, in order to arrest the further combustion of the phosphorus, and to neutralize any acid which may have been formed.

PHYSALIS ALKEKENGI. *Common Winter Cherry.* A perennial herbaceous plant, growing wild in the South of Europe, and cultivated in our gardens. The fruit is a round red berry, about as large as a cherry, enclosed in the calyx, and containing numerous flat kidney-shaped seeds. The berries are very juicy, and have an acidulous, bitterish taste. The calyx is very bitter. By drying they shrink, and become of a brownish red colour. They are said to be aperient and diuretic, and have been highly recommended in suppression of urine, gravel, and other complaints of the urinary passages. From six to twelve cherries, or an ounce of the expressed juice, may be taken for a dose; and even much larger quantities are not injurious. They are consumed to a considerable extent in some parts of Europe as food. The berries of the *Physalis viscosa* of this country, are said by Clayton to be a remarkable diuretic.

PICHURIM BEANS. The seeds of a tree not well known (*Laurus Pichurim*, Richard, *Ocotea Pichurim*, Kunth), growing in Brazil, Guiana, Venezuela, and other parts of South America. The beans are the kernels of the fruit separated into halves. They are ovate-oblong or elliptical, flat on one side, convex on the other, of a grayish-brown colour externally, chocolate coloured within, of an aromatic odour between that of nutmegs and sassafras, and of a spicy pungent taste. There are two kinds, one about an inch and a half long by half an inch in breadth, the other little more than half as large, rounder, and of a dark brown colour. Their virtues depend on a volatile oil. In medical properties they resemble the aromatics in ordinary use, and may be employed for the same purposes. They are very rare in this country.

PIMPINELLA SAXIFRAGA. *Small Burnet Saxifrage. Saxifraga.* A perennial umbelliferous European plant, growing on sunny hills, and in dry meadows and pastures. The root is ranked among officinal remedies in some parts of Europe. It has a peculiar, strong, aromatic, yet unpleasant odour, and a sweetish, pungent, biting, aromatic. bitterish taste. Its active constituents are volatile oil, and an acrid resin. It is considered diaphoretic, diuretic, and stomachic; and has been used in chronic catarrh, asthma, dropsy, amenorrhœa, &c. The dose in substance is about half a drachm, and in infusion two drachms. The root is also used as a masticatory in toothach, as a gargle in palsy of the tongue and in collections of viscid mucus in the throat, and externally to remove freckles.

PINCKNEYA PUBENS, Michaux. A large shrub or small tree, growing in South Carolina, Georgia, and Florida, in low and moist places along the sea coast. It is closely allied, in botanical characters, to the Cinchonæ, with which it is ranked by some botanists, though it certainly does not belong to that genus as defined by De Candolle. The bark is bitter, and has been used with advantage in intermittent fever. Dr. Law, of Georgia, cured six out of seven cases in which he administered it. The dose and mode of preparation are the same with those of cinchona. The chemical composition and medical properties of this bark deserve a fuller investigation than they have yet received.

PLANTAGO MAJOR. *Plantain.* A well known perennial herb, growing in fields, by the roadsides, and in grass plats, and abounding both in Europe and this country. The leaves are saline, bitterish, and austere to the taste, the root saline and sweetish. The plant has been considered refrigerant, diuretic, deobstruent, and somewhat astringent. The ancients esteemed it highly, and employed it in visceral obstructions, hemorrhages, particularly from the lungs, consumption, dysentery, and other complaints. In modern times it has been applied to similar purposes, and the root is said to have proved useful in intermittents. At present, however, it is generally believed to be very feeble, and is little used internally. As an external application it has been recommended in ulcers of various kinds, and in indolent tumours of a scrofulous character. Among the vulgar it is still much used as a vulnerary, and as a dressing for blisters and sores. The dose of the expressed juice is from one to four fluidounces. Two ounces of the fresh root or leaves may be boiled in a pint of water and given during the day. Externally, the leaves are applied in substance or decoction. The *Plantago media*, and the *P. lancifolia* or *rib-grass*, which are also indigenous species, possess properties similar to those of the P. major, and may be used for the same purposes.

Under the name of *semen psyllii*, the seeds of several species of Plantago, growing in different parts of Europe, are sometimes kept in the shops. The best are obtained from the *Plantago Psyllium* or *fleawort*, which grows in the South of Europe and Barbary. They are small, about a line long by half a line in breadth, convex on one side, concave on the other, flea-coloured, shining, inodorous, and nearly tasteless, but very mucilaginous when chewed. They are demulcent and emollient, and may be used internally and externally in the same manner as flaxseed, which they closely resemble in medical properties.

PLUMBAGO EUROPŒA. *Leadwort. Dentellaria.* A perennial, herbaceous plant, growing in the South of Europe. It has an acrid taste, and when chewed, excites a flow of saliva. This is particularly the case with the root, which has been long used to relieve toothach. Hence the plant derived the name of *dentelaire*, by which it is known in France. A decoction of the root in olive oil has been highly recommended for the cure of the itch. Writers differ much in their statements in relation to the activity of the plant, some speaking of it as rubefacient, vesicatory, and caustic, and when swallowed, as violently emetic and liable to produce dangerous irritation of the alimentary canal; while others consider it nearly inert. Perhaps the difference may be ascribed in part to the use of the plant in the recent state in one case, and dried or long kept in the other. A crystallizable, acrid principle, called *plumbagin*, has been extracted from the root by Dulong.

POLYPODIUM VULGARE. *Common Polypody.* A fern belonging both to the old and new continents, and growing in the clefts of old walls, rocks, and decayed trunks of trees. The root, which is the part considered medicinal, is rather long, about as thick as a goosequill, somewhat contorted, covered with brown, easily separable scales, furnished with slender radicles, and marked by numerous small tubercles. As found in the shops, it is sometimes destitute of the scales and radicles. Its colour is reddish-brown with a tinge of yellow, its odour disagreeably oleaginous, its taste peculiar, sweetish, somewhat bitter, and nauseous. The root of the variety growing upon the oak has been preferred, though without good reason. It was deemed purgative by the ancients, who employed it for the evacuation of bile and pituitous humours, in melancholic and maniacal cases. Modern physicians have used it in similar complaints, and as a pectoral in chronic catarrh and asthma. At present, however, it is scarcely ever employed, being considered nearly inert. It was given in doses varying from one or two drachms to an ounce, usually in connection with cathartic medicines.

POPULUS. *Poplar.* Several trees belonging to this genus of plants have attracted some attention in a medical point of view. In most of them, the leaf-buds are covered with a resinous exudation, which has a peculiar, agreeable, balsamic odour, and a bitterish, balsamic, somewhat pungent taste. This is abundant in the buds of the *Populus nigra* or *black poplar* of Europe, which are officinal in some parts of that continent. They contain resin and a peculiar volatile oil. The buds of the *P. balsamifera*, growing in the northern parts of this continent and Siberia, are also highly balsamic; and a resin is said to be furnished by the tree, which is sometimes, though erroneously, called *tacamahac*. The virtues of the poplar buds are probably analogous to those of the turpentines and balsams. They have been used in pectoral, nephritic, and rheumatic complaints, in the form of tincture; and a liniment, made by macerating them in oil, has been applied externally in cases of local rheumatism. The *Unguentum Populeum* of European pharmacy, is made, according to the directions of the Paris Codex, by macerating 500 parts of the fresh buds of the black poplar, in 1500 parts of melted lard for 24 hours, preserving the mixture till the other plants employed arrive at maturity, then adding of the bruised fresh leaves of the black poppy, deadly nightshade, henbane, and black nightshade (*Solanum nigrum*), each 128 parts, boiling the mixture with a gentle fire till the moisture is dissipated, then straining with expression, and allowing the ointment to cool after defecation. This is an anodyne ointment, occasionally employed in Europe as an application in painful local affections.

The bark of some species of poplar is possessed of tonic properties, and has been used in intermittent fever with advantage. Such is the case with that of the *P. tremuloides* or *American aspen*, and of the *P. tremula* or *European aspen*. In the bark of the latter species, Braconnot found *salicin*, and another proximate crystallizable principle which he named *populin*. It is in these principles, probably, that the febrifuge properties of the bark reside. They may be obtained by precipitating a saturated decoction of the bark with solution of subacetate of lead, filtering, precipitating the excess of lead by sulphuric acid, again filtering, evaporating, adding animal charcoal towards the end of the evaporation, and filtering the liquor while hot. Salicin gradually separates, upon the cooling of the liquor, in the form of crystals. If, when this principle has ceased to crystallize, the excess of sulphuric acid in the liquid be saturated by a concentrated solution of carbonate of potassa, the populin will be precipitated. If this be pressed between folds of blotting paper, and redissolved in boiling water, it will be thrown down, upon the cooling of the liquid, in the crystalline state. The leaves of the *P. tremula* also afford populin, and in larger proportion even than the bark. It is probable that both principles exist also in the bark of the *P. tremuloides*, and some other species. Salicin is described under the head of *Salix*. *Populin* is very light, of a pure white colour, and of a bitter, sweetish taste, analogous to that of liquorice. When heated it readily melts into a colourless and transparent liquid. It is soluble in 2000 parts of cold, and about 70 parts of boiling water; and is more soluble in boiling alcohol. Acetic acid and the diluted mineral acids dissolve it, and upon the addition of an alkali, let it fall unchanged.

PORTULACA OLERACEA. *Garden Purslane.* An annual succulent plant, growing in gardens and cultivated grounds in the United States, Europe, and most other parts of the globe. It has an herbaceous, slightly saline taste, and is often used as greens, being boiled with meat, or other vegetables. It is considered a cooling diuretic, and is recommended in scorbutic diseases, and affections of the urinary passages. The seeds have been considered anthelmintic; but they are tasteless and inert.

POTENTILLA REPTANS. *Cinquefoil.* A perennial, creeping, European herb, with leaves which are usually quinate, and have thus given origin to the ordinary name of the plant. The root has a bitterish, styptic, slightly sweetish taste, and was formerly used in diarrhœa and other complaints for which astringents are usually prescribed.

PRUNELLA VULGARIS. *Self-heal. Heal-all.* A small perennial labiate plant, common both in Europe and in the United States, growing especially by the way-sides. It is inodorous, but has an austere bitterish taste. The herb in flower was formerly used, in the state of infusion or decoction, in hemorrhages and diarrhœa, and as a gargle in sore-throat. In this country, it is not employed in regular practice.

PULMONARIA OFFICINALIS. *Lung-wort.* An herbaceous perennial, indigenous in Europe, and sometimes cultivated in this country in gardens. The leaves, which are the part used, are inodorous, and have an herbaceous, somewhat mucilaginous, and feebly astringent taste. They have been considered pectoral and demulcent, and have been employed in catarrh, hæmoptysis, consumption, and other affections of the chest; but their virtues are doubtful, and they were probably applied to the treatment of pectoral complaints as much on account of the supposed resemblance of their speckled surface to that of the lungs, as from the possession of any positively useful properties.

PUMICE STONE. *Pumex.* A very light porous stone, found in the vicinity of active or extinct volcanoes, and believed to have been thrown up during their eruption. The pumice stone of commerce is said to be obtained chiefly from Lipari. It is used whole, in the manner of a file, for removing the outer surface of bodies, or for rubbing down inequalities, and, in the state of powder, for polishing glass, metals, stones, &c.; purposes to which it is adapted by the hardness of its particles.

PYRETHRUM PARTHENIUM, Willd. *Matricaria Parthenium*, Linn. *Chrysanthemum Parthenium*, Pers. *Feverfew.* A perennial herbaceous plant, about two feet high, with an erect, branching stem, pinnate leaves, oblong, obtuse, gashed, and dentate leaflets, and compound flowers borne in a corymb upon branching peduncles. It is a native of Europe, but cultivated in our herb gardens. The whole herbaceous part is used. The plant has an odour and taste analogous to those of chamomile, which it resembles also in the appearance of its flowers, and in its medical properties. Though little employed, it is undoubtedly capable of useful application as a mild tonic.

REALGAR. This is the protosulphuret of arsenic, consisting of one equiv. of arsenic 37.7, and one of sulphur 16.1=53.8. It is found native in Saxony, Bohemia, Transylvania, and in various volcanic regions. Realgar is artificially made by melting arsenious acid with about half its weight of sulphur. (*Turner.*) Thus prepared, it is of a crystalline texture, of a beautiful ruby-red colour, of a uniform conchoidal fracture, somewhat transparent in thin layers, and capable of being sublimed without change. Native realgar is said to be innocent when taken internally, while that artificially prepared is poisonous, in consequence, according to Guibourt, of containing a little arsenious acid. Realgar is used only as a pigment.

RED CHALK. *Reddle.* A mineral substance of a deep red colour, of a compact texture, dry to the touch, adhering to the tongue, about as hard as chalk, soiling the fingers when handled, and leaving a lively red trace when drawn over paper. It consists of clay and oxide of iron, and is intermediate between *bole* and *red ochre*, containing more oxide of iron than the former, and less than the latter. It is used for drawing lines upon wood, &c., and is sometimes made into crayons by levigating and elutriating it, then forming it into a paste with mucilage of gum Arabic, moulding this into cylinders, and drying it in the shade. It has been used internally as an absorbent and astringent.

RESEDA LUTEOLA. *Weld. Dyer's-weed.* An annual European plant, naturalized in the United States. It is inodorous, and has a bitter taste, which is very adhesive. In medicine it has been employed as a diaphoretic and diuretic, but is now neglected. On the continent of Europe it is much employed for dyeing yellow, and before the introduction of quercitron into England, was extensively employed for the same purpose in that country. The whole plant is used.

RIGA BALSAM. *Balsamum Carpaticum. Balsamum Libani.* This is a product of the *Pinus Cembra*, a large tree growing in the mountainous regions and northern latitudes of Europe and Asia. The juice exudes from the extremities of the young twigs, and is collected in flasks suspended from them. It is a thin white fluid, having an odour analogous to that of juniper, and possessing the ordinary terebinthinate properties. In this country it is very rare; but it is occasionally brought from Riga or Cronstadt in bottles. A similar product, called *Hungarian balsam*, is obtained in the same manner, from the *Pinus Pumilio*, growing on the mountains of Switzerland, Austria, and Hungary. It is scarcely known in the United States.

ROTTEN STONE. *Terra cariosa.* An earthy mineral, occurring in light, dull, friable masses, dry to the touch, of a very fine grain, and of an ash-brown colour. It is obtained from Derbyshire in England, and is used for polishing metals.

SALEP. Though not directed by any of the British Colleges, nor by our national Pharmacopœia, this substance deserves a slight notice, as it is frequently mentioned by writers on the Materia Medica, and is occasionally to be found in the shops. The name is given to the prepared bulbs of the *Orchis mascula* and other species of the same genus, belonging to the Linnæan class and order *Gynandria Monandria*, and to the natural family of the *Orchideæ.* The *male orchis* is a native of Europe, the Levant, and northern Africa. Its bulbs, which are two in number, oval or roundish, internally white and spongy, are prepared by removing their epidermis, plunging them into boiling water, then stringing them together, and drying them in the sun or by the fire. By this process they acquire the appearance and consistence which distinguish them as found in the shops. They were formerly procured exclusively from Asia Minor and Persia, but are now prepared in France and perhaps other parts of Europe.

Salep is in small, oval, irregular masses, hard, horny, semitransparent, of a yellowish colour, a feeble odour, and a mild mucilaginous taste. It is sometimes kept in the state of powder. In composition and relation to water it is closely analogous to tragacanth, consisting of a substance insoluble, but swelling up in cold water (*bassorin*,) of another in much smaller proportion, soluble in cold water, and of minute quantities of saline matters. It is highly nutritive, and may be employed for the same purposes with tapioca, sago, &c. The reputation which it enjoyed among the ancients, and still enjoys in the East, of possessing aphrodisiac properties, is wholly without foundation.

SANDARACH. *Sandaraca.* This is a resinous substance obtained from the *Thuya articulata*, a small evergreen tree growing in the North of Africa. It is in small, irregular, roundish oblong grains or tears, of a pale yellow colour sometimes inclining to brown, more or less transparent, dry and brittle, breaking into a powder under the teeth, of a faint agreeable odour increased by warmth, and of a resinous slightly acrid taste. It melts with heat, diffusing a strong balsamic odour, and easily inflames. It is almost entirely soluble in ordinary alcohol, and entirely so in that liquid when anhydrous, and in ether. Heated oil of turpentine also dissolves the greater part of it, but very slowly. According to Unverdorben, it consists of three different resins, varying in their relations to alcohol, ether, and the oil of turpentine. The *sandaracin* of Geise, which remains after sandarach has been exposed to the action of ordinary alcohol, is a mixture of two of these resins. Sandarach was formerly given internally as a medicine, and entered into the composition of various ointments and plasters. At present it is used chiefly as a varnish. It is sometimes employed as incense, and its powder is rubbed upon paper in order to prevent ink from spreading, after letters have been scratched out.

SAPONARIA OFFICINALIS. *Soapwort.* A perennial herbaceous plant, growing wild in this country, in the vicinity of cultivation, but probably introduced from Europe. It is commonly known by the vulgar name of *bouncing bet.* It is one or two feet high, with smooth, lanceolate leaves, and clusters of conspicuous whitish or slightly purplish flowers, which appear in July and August. The root and leaves are employed. They are inodorous, and of a taste at first bitterish and slightly sweetish, afterwards somewhat pungent, continuing long, and leaving a slight sense of numbness on the tongue. They impart to water the property of forming a lather when agitated, like a solution of soap, whence the name of the plant was derived. This property, as well as the medical virtues of the plant, reside in a peculiar extractive matter, obtained from the root by Bucholz, and called by him *saponin.* This principle constitutes, according to Bucholz, 34 per cent. of the dried root, which contains also a considerable quantity of gum and a little bassorin, resin, and altered extractive, besides lignin and water. *Saponin* is obtained, though not absolutely pure, by treating the watery extract with alcohol and evaporating. It is brown, somewhat translucent, hard and brittle, with a sweetish taste, followed by a sense of acrimony in the fauces. It is soluble in water and officinal alcohol, but is insoluble in anhydrous alcohol, ether, and the volatile oils. Its watery solution froths when agitated. Soapwort has been much used in Germany as a remedy in venereal and scrofulous affections, cutaneous eruptions, and visceral obstructions. It appears to act as an alterative, like sarsaparilla, to which it has been deemed superior in efficacy by some physicians. The plant is given in the forms of decoction and extract, which may be freely taken. From two to four pints of the decoction daily are recommended in lues. The inspissated juice, given in the quantity of half an ounce in the course of a day, is said by Andry generally to cure gonorrhœa in about two weeks, without any other remedy.

SARCOCOLLA. A peculiar vegetable product, exuding spontaneously from the *Penæa Sarcocolla*, *P. mucronata*, and other species of Penæa, small shrubs growing at the Cape of Good Hope, in Ethiopia, Arabia, &c. It is in the form of small, roundish, irregular grains, sometimes agglutinated in masses, friable, opaque or semi-transparent, of a yellowish or brownish-red colour, inodorous unless heated, when they have an agreeable smell, and of a peculiar, bitter, sweetish, and acrid taste. Sarcocolla, according to Pelletier, consists of 65.3 per cent. of a peculiar substance, considered by Dr. Thomson as holding an intermediate place between gum and sugar, and called *sarcocollin* or pure sarcocolla, 4.6 of gum, 3.3 of a gelatinous matter having some analogy with bassorin, and 26.8 of lignin, &c. It is said to be purgative, but at the same time to produce serious inconvenience by its acrid properties. The Arabian physicians used it internally; and by the ancients it was employed as an external application to wounds and ulcers, under the idea that it possessed the property of agglutinating the flesh, whence its name was derived. It is at present out of use.

SASSA GUM. This name has been applied by Guibourt to a gum, occasionally brought into market from the East, and answering so exactly to Bruce's description of the product of a tree which he calls *sassa*, that there is reason to believe in their identity. According to Guibourt's description, it is in mammillary masses, or in convoluted pieces resembling an ammonite, of a reddish colour, and somewhat shining surface, and more transparent than tragacanth. Its taste is like that of tragacanth, but slightly acrid. When introduced into water, it becomes white, softens, and swells to four or five times its original bulk; but it preserves its shape, neither like tragacanth forming a mucilage, nor, like Bassora gum, separating into distinct flocculi. It is rendered blue by iodine.

SATUREJA HORTENSIS. *Summer Savory*. An annual labiate plant, growing spontaneously in the South of Europe, and cultivated in gardens as a culinary herb. It has an aromatic odour and taste, analogous to those of thyme, and was formerly used as a gentle carminative stimulant; but it is now employed only to give flavour to food. The *S. montana* or *winter savory*, which is also cultivated in gardens, has similar properties, and is similarly employed.

SCOLOPENDRIUM OFFICINARUM, Smith. *Asplenium Scolopendrium*, Linn. *Harts-tongue*. A fern indigenous in Europe and America. Its vulgar name was derived from the shape of its leaves, which were the part formerly used in medicine. They have a sweetish, mucilaginous, and slightly astringent taste, and, when rubbed, a disagreeable oily odour. They have been used as a deobstruent in visceral affections, as an astringent in hemorrhages and fluxes, and as a demulcent in pectoral complaints; but their properties are feeble, and they have been superseded by more active medicines.

SCUTELLARIA LATERIFLORA. *Scullcap*. This is an indigenous perennial herb, belonging to the Linnæan class and order *Didynamia Gymnospermia*, and to the natural order *Labiatæ*. Its stem is erect, much branched, quadrangular, smooth, and one or two feet high. The leaves are ovate, acute, dentate, subcordate upon the stem, opposite, and supported upon long petioles. The flowers are small, of a pale blue colour, and disposed in long, lateral, leafy racemes. The calyx has an entire margin, which, after the corolla has fallen, is closed with a helmet-shaped lid. The tube of the corolla is elongated, the upper lip concave and entire, the lower three-lobed. The plant grows in moist places, by the sides of ditches and ponds, in all parts of the Union. To the senses it does not indicate, by any peculiar taste or smell, the possession of remarkable medicinal virtues. It is even destitute of the aromatic properties which are found in many of the labiate plants. When taken internally, it produces no obvious effects upon the system. Notwithstanding this apparent inertness, it obtained, at one period, extraordinary credit throughout the United States as a preventive of hydrophobia, and was even thought to be useful in the disease itself. A strong infusion of the plant was given in the dose of a teacupful, repeated several times a day, and continued for three or four months after the bite was received; while the herb itself was applied to the wound. Strong testimony has been adduced in favour of its prophylactic powers; but it has already shared the fate, which in this case is no doubt deserved, of numerous other specifics against hydrophobia, which have been brought into temporary popularity only to be speedily abandoned. The *Scutellaria galericulata* or common *European scullcap*, which also grows wild in this country, has a feeble, somewhat alliaceous odour, and a bitterish taste. It has been employed in intermittents, and externally in old ulcers, but is now out of use. Another indigenous species—the *S. integrifolia*, of which the *S. hyssopifolia*, Linn., is considered by some as a variety, has an intensely bitter taste, and might probably be found useful as a tonic.

SECALE CEREALE. *Rye.* Syria, Armenia, and the southern provinces of Russia, have been severally indicated by different authors as the native country of rye. The plant is now cultivated in all temperate latitudes. The *grains* consist, according to Einhof, of 24.2 per cent. of envelope, 65.6 of flour, and 10.2 of water. The *flour*, according to the same chemist, consists of 61.07 per cent. of starch, 9.48 of gluten, 3.28 of albumen, 3.28 of uncrystallizable sugar, 11.09 of gum, 6.38 of vegetable fibre, besides 5.62 of loss, comprising an acid, the nature of which was not determined. Rye flour is much used, in the dry state, as an external application to erysipelatous inflammation, and other eruptive affections, the burning and unpleasant tingling of which it tends to allay, while it absorbs the irritating secretions. In the form of mush, it is an excellent laxative article of diet; and mixed with molasses, it may be given with great advantage in hemorrhoidal affections and prolapsus ani, connected with constipation.

SEDUM ACRE. *Biting Stone-crop. Small Houseleek.* A small, perennial, succulent European plant, growing on rocks and old walls, with stems about as long as the finger, and numerous very minute leaves. It is without odour, and has a taste which at first is cooling and herbaceous, afterwards burning and durably acrid. Taken internally it vomits and purges, and applied to the skin, produces inflammation and vesication. The fresh herb and the expressed juice have been used as an antiscorbutic, emetic, cathartic, and diuretic, and have been applied locally to old ulcers, warts, and other excrescences; but the plant is at present little employed. It has recently been recommended in Germany as a remedy in epilepsy. Other species of Sedum are less acrid, and are even eaten as salad in some parts of Europe. Such are the *S. rupestre* and *S. album*. The *S. Telephium* was formerly employed externally to cicatrize wounds, and internally as an astringent in dysentery and hæmoptysis; and is still esteemed by the common people in France as a vulnerary.

SEMPERVIVUM TECTORUM. *Common Houseleek.* A perennial succulent European plant, growing on rocks, old walls, and the roofs of houses, and remarkable for its tenacity of life. It is occasionally cultivated in this country as an ornament to the walls of houses, or as a domestic medicine. The leaves, which are the part used, are oblong, pointed, from half an inch to two inches in length, thick, fleshy, succulent, flat on one side, somewhat convex on the other, smooth, of a light green colour, inodorous, and of a cooling, slightly saline, astringent, and sourish taste. They are employed, in the recent state and bruised, as a cooling application to burns, stings of bees, hornets, &c., ulcers, and other external affections attended with inflammation. They contain a large proportion of supermalate of lime.

SENECIO VULGARIS. *Common Groundsel.* An annual European plant, introduced into this country, and growing in cultivated grounds. The whole herb is used, and should be gathered while in flower. It has, when rubbed, a peculiar rather unpleasant odour, and a disagreeable, herbaceous, somewhat bitterish and saline taste, followed by a sense of acrimony. It is emetic in large doses, and has been given in convulsive affections, liver complaints, spitting of blood, &c., but is now very little used. The bruised herb is sometimes applied externally to painful swellings and ulcers. The plant is employed also as food for birds, which are very fond of it. Other species of Senecio have also been medicinally used; and an indigenous species, the *S. aureus* or *ragwort*, is said by Schoepf to be a favourite vulnerary with the Indians.

SIENNA. *Terra di Sienna.* An argillaceous mineral, compact, of a fine texture, very light, smooth and glossy, of a yellowish-brown or coffee colour, leaving a dull orange trace when moistened and drawn over paper. By calcination it assumes a reddish-brown colour, and is then called *burnt sienna*. In both the raw and burnt states it is used for painting. The best sienna is brought from Italy, but an inferior kind is found in England.

SILENE VIRGINICA. *Catch-fly. Wild Pink.* An indigenous perennial plant, growing in Western Virginia and Carolina, and in the states beyond the Alleghany mountains. Dr. Barton, in his "Collections," states that a decoction of the roots is said to be efficacious as an anthelmintic. We are told that it is considered poisonous by some of the Indians. The *S. Pennsylvanica*, which grows in the Eastern section of the Union, from New York to Virginia, probably possesses similar properties.

SISYMBRIUM OFFICINALE, Scopoli. *Erysimum officinale*, Linn. *Hedge Mustard.* A small annual plant, growing both in the United States and Europe, along the road-sides, by walls and hedges, and on heaps of rubbish. It has an herbaceous somewhat acrid taste, which is strongest in the tops and flower-spikes, and resembles that of mustard, though much weaker. The seeds have considerable pungency. The herb is said to be diuretic and expectorant, and has been recommended in chronic coughs, hoarseness, and ulceration of the mouth and fauces. The juice of the plant may be used mixed with honey or sugar, or the seeds may be taken in substance. The *Sisymbrium Sophia* or *flix weed* is also among the plants formerly considered officinal. It is of a pungent odour when rubbed, and of an acrid biting taste. The herb has been used externally in indolent ulcers, and the seeds internally in worms, calculous complaints, &c.

SIUM NODIFLORUM. *Water-parsnip.* A perennial, umbelliferous, aquatic European plant, growing also in the Southern section of the United States, where it is supposed to have been introduced. It is commonly considered poisonous; but the expressed juice, given by Withering in the dose of three or four ounces every morning, was not found to affect the head, stomach, or bowels. He found it, in this quantity, very advantageous in obstinate cutaneous diseases; and the plant has been usefully employed by others in similar complaints, and in scrofulous swellings of the lymphatic glands. It is considered diuretic. The *S. latifolium*, which grows in Europe and the United States, and is the common water-parsnip of this country, is positively asserted to be poisonous; and madness and even death are said to have followed the use of the root. The *S. Sisarum* or *skirret*, a plant of Chinese origin, cultivated in Europe, has a sweetish, somewhat aromatic root, which is employed as food in the form of salad, and is supposed to be a useful diet in complaints of the chest.

SMALT. *Azure.* When the impure oxide of cobalt, obtained by roasting the native arseniuret of that metal, is heated with sand and potassa, the mixture melts, and a beautiful blue glass results, which, when reduced to powder, receives the name of smalt. It is used chiefly in painting.

SOOT. *Fuligo Ligni.* This well known substance has a peculiar smell, and a bitter, empyreumatic, and disagreeable taste. Its composition is very complex. Reduced to powder and treated with water, it affords an infusion of a deep yellow or brown colour, the colour being deeper if heat be employed. The insoluble portion amounts to about forty-four per cent. The soluble part consists chiefly, according to Berzelius, of a pyrogenous resin united with acetic acid, called *acid pyretin*, and saturated with potassa, lime, and magnesia. It also contains sulphate of lime, chloride of potassium, acetate of ammonia, and traces of nitric acid. If the solution be evaporated to dryness, it furnishes a black extract. This forms with water a blackish brown solution, which, when treated with any free acid, except the acetic, lets fall the acid pyretin, in the form of a black mass, resembling pitch; while the acid employed remains in solution with the bases previously in combination with the pyretin. Braconnot thought he had discovered in the pyretin, a peculiar principle, to which he gave the name of *asbolin;* but Berzelius thinks he was mistaken. Besides these substances, Braconnot ascertained the existence in soot of an azotized extractive matter to the amount of twenty per cent. This matter when submitted to dry distillation, afforded a considerable portion of pyrogenous oil. The soot itself, when subjected to a similar distillation, furnished one-fifth of its weight of empyreumatic oil. To the above ingredients of soot, must be added creosote, which was not discovered at the date of the researches of Berzelius and Braconnot, and to the presence of which soot is supposed to owe its medicinal properties.

Soot was formerly officinal with the Edinburgh College, and the Scotch physicians were in the habit of frequently prescribing it as a tonic and antispasmodic in the form of tincture. It went very much out of use in regular practice; and it is only within a few years, that its employment has been revived on account of its containing creosote. At present it is chiefly used as an external remedy in the form of decoction or ointment. In the *Revue Med.* for June 1834, M. Bland details a number of cases of various affections, such as obstinate tetters, porrigo favosa, psora, fistula, cancerous and venereal ulcers, chronic irritations of the lining membrane of the mouth, exudations from the mucous membrane of the nose, herpetic eruptions of the genital organs, and pruritus of the vulva, in which the use of soot effected a cure. The *decoction* is made by adding two handfuls of soot to a pint of water, boiling for half an hour and filtering. It is applied as a lotion to the affected parts; or injected into the fistulæ, several times a day, and, in the intervals, the part, if accessible, is dressed with an *ointment*, made by rubbing up a drachm of finely powdered soot with an ounce of lard. In cases of porrigo, the crusts must be removed by poultices, before the soot is applied. In scrofulous ophthalmia, M. Caron Duvillards, and M. Baudeloque have found a collyrium, made according to the following formula, very useful. Dissolve two ounces of soot in boiling water, filter the solution and evaporate it to dryness. Dissolve the dry residue, with the assistance of heat, in strong white wine vinegar, and add extract of roses in the proportion of twenty-four grains to twelve fluidounces of the liquid. It is prepared for use by adding a few drops of the liquid to a glass of water. (*Bull. Gen. de Therapeutique, Mars* 1834.) This formula is not very satisfactory, as it does not indicate the proportions of water and vinegar to be employed.

We are informed by Dr. Hewson of this city that he found an infusion of soot, an efficacious remedy, employed by injection, in cases of ascarides. In one case, of long standing in an adult, in which a number of remedies had been tried unsuccessfully, injections of soot daily, persevered in for two weeks, effected a complete cure. The injection was made by adding a cupful of soot to a pint of boiling water, and straining the solution. An *infusion of hickory ashes and soot* has formed, for some time past, a popular remedy for dyspepsia. It is made by infusing a pint of clean hickory ashes, and a gill of soot in half a gallon of boiling water, allowing the liquor to stand for twenty-four hours, and then decanting. Of this a small wineglassful is to be taken three or four times a day. No doubt this infusion has been useful in acidity of stomach; but its indiscriminate use in all gastric affections popularly confounded under the name of dyspepsia, is calculated to do much harm.

Soot is employed in the arts as a colouring matter. Meat, which has been allowed to remain from half an hour to an hour in an infusion of one part of soot to six parts of cold water, keeps like smoked meat. From this fact it is evident that soot is a good antiseptic.

SPANISH BROWN. A brownish-red ochre, much used in painting.

SWIETENIA FEBRIFUGA. A large tree growing in the East Indies. The bark is the portion medicinally employed. It is smooth and red internally, rough and gray on the outer surface, of a feeble aromatic odour, and an astringent bitter taste. Water extracts its virtues by infusion or decoction. It is said to have been much used in India as a substitute for Peruvian bark, to which it is somewhat analogous in medical properties, though it contains neither cinchonia nor quinia. The dose of the powder is from thirty grains to half a drachm. The watery extract has the virtues of the bark.

The *Swietenia Mahagoni* or *Mahogany-tree*, which grows in the West Indies and other parts of tropical America, has also a bitter astringent bark, which resembles that of the S. febrifuga in virtues as well as in sensible properties. The wood of this tree is the mahogany so much used in ornamental wood-work.

SYMPHYTUM OFFICINALE. *Comfrey.* A perennial European plant, cultivated in our gardens for medical use. Its root, which is the part used, is spindleshaped, branched, often more than an inch thick and a foot long, externally smooth and blackish, internally white, fleshy, and juicy. By drying, it becomes wrinkled, of a firm horny consistence, and of a dark colour within. It is almost inodorous, and has a mucilaginous, feebly astringent taste. Among its constituents are mucilage, in great abundance, and a small quantity of tannin. It was formerly highly esteemed as a vulnerary, but has lost its credit in this respect. Its virtues are chiefly those of a demulcent, and it may be advantageously used for all the purposes to which the marshmallow is applied. It is a very common ingredient in the domestic cough mixtures employed in chronic catarrhs, consumption, and other pectoral affections. The most convenient form of administration is that of decoction, which may be made either from the fresh or dried root. According to Lewis, comfrey root yields to water a larger proportion of mucilage than the root of the Althæa.

TACAMAHAC. *Tacamahaca.* The resinous substance commonly known by this name, is supposed to be derived from the *Fagara octandra* of Linn. (*Elaphrium tomentosum*, Jacq., *Amyris tomentosum*, Spreng.), a tree of considerable size, growing in the island of Curacoa, and in Venezuela. The juice exudes spontaneously, and hardens on exposure. As brought into the market, it is in irregularly shaped pieces of various sizes, some not larger than a mustard seed, others as much as an inch or two inches in diameter. The colour is usually light yellowish or reddish-brown; but in the larger masses is more or less diversified. The pieces are in general translucent, though frequently covered with powder upon their surface, so as to render them apparently opaque. They are heavier than water, brittle, and pulverizable, yielding a pale yellow powder. Their odour is resinous and agreeable, their taste bitter, balsamic, and somewhat acrid. Exposed to heat they melt and exhale a stronger odour. Tacamahac is partially soluble in alcohol, and completely so in ether and the fixed oils. It consists of resin with a little volatile oil.

Another variety is obtained from the East Indies, and called *tacamahaca orientale*, or *tacamahaca in testis*. It is supposed to be derived from the *Calophyllum Inophyllum;* and comes into the market in gourdshells covered with rush leaves. It is of a pale yellow colour inclining to green, slightly translucent, soft and adhesive, of an agreeable odour, and an aromatic bitterish taste. It is at present very rare in commerce.

Guibourt describes several other varieties of tacamahac, which, however are little known. Among them is a soft, adhesive, dark green resin, said to be procured from the *Calophyllum Tacamahaca* of Willd., a tree growing in the islands of Bourbon and Madagascar.

Tacamahac was formerly highly esteemed as an internal remedy, but is now employed medicinally only in the composition of ointments and plasters, and little even for this purpose. Its properties are analogous to those of the turpentines. It is sometimes used as incense.

TANNIN. *Tannic acid.* Since the publication of the experiments of M. Pelouze, this substance has been universally admitted to rank with the acids, and is consequently denominated, in recent chemical works, *tannic acid.* Its extensive diffusion in vegetables, the wide circle of its affinities, and the consequent influence which it exercises in numerous pharmaceutical operations, both extemporaneous and officinal, are sufficient grounds, independently of its effects as a remedial agent, for giving it a place in this work, though it does not rank among the medicines or preparations directed either in the United States or British Pharmacopœias.

The term *tannin*, like the term sugar, resin, &c. has been considered as applicable not so much to one distinct proximate principle, invariable in its character and composition, as to a set of substances, which, though differing somewhat in their nature, are very closely allied to each other, and possess many properties in common. It has been observed, that tannin, as procured from certain vegetables, affords, with a solution of a persalt of iron, a black precipitate, and colours the liquid deep blue; while, as furnished by others, it gives a grayish-green precipitate with the same solution, and colours the liquid green. Hence has arisen a distinction of this substance into two varieties; 1. *tannin which is rendered black or blue*, and 2. *tannin which is coloured green*, by the persalts of iron. The first, which is the most abundant, is that found in the different species of oak, and consequently in galls; the second exists in Peruvian bark, catechu, and various other vegetable products. It has not yet been determined whether these are really distinct bodies, or whether their difference is not ascribable to the presence of foreign substances in one or both. As they do not materially differ in other respects, and as the tannin procured from galls is that which has attracted most attention, we shall confine our observations to this variety.

Numerous processes for obtaining tannin in a state of purity have been proposed; but most of them are complex, and, in consequence of the readiness with which this principle undergoes alteration, are insufficient for the end in view. The process of M. Pelouze has superseded all others, being preferable both for its facility and the purity of the resulting preparation. An elongated narrow glass vessel, open at both ends, is taken. The lower orifice is loosely closed by a piece of linen or cotton; and above this is placed some very fine powder of galls, which is lightly pressed together, and added till it fills half the capacity of the vessel. Sulphuric ether is then poured upon the powder till it fills the vessel, the upper aperture of which is afterwards closed to prevent the evaporation of the ether. The apparatus is placed in the mouth of a bottle, in which the ether is received as it percolates through the galls. The water always present in the ether of the shops dissolves the tannin, to the exclusion of all the other principles of the galls, and forms a saturated solution, which separates from the ether, and remains as a distinct layer at the bottom of the bottle. When the powder has been exhausted by the addition of successive portions of the solvent, the apparatus is taken apart, the ether is separated from the aqueous solution of tannin beneath it, and the latter, after being washed with some fresh ether, is evaporated by a very gentle heat, or in a vacuum with sulphuric acid. From 35 to 40 per cent. of tannin is thus obtained from galls.

Pure tannin is solid, uncrystallizable, white or very slightly yellowish, inodorous, strongly astringent to the taste without bitterness, very soluble in water, much less soluble in alcohol and ether, especially when anhydrous, and insoluble in the fixed and volatile oils. It may be kept unchanged in the solid state. Exposed to heat, it partly melts, swells up, blackens, takes fire, and burns with a brilliant flame. The aqueous solution, when exposed to the air, gradually becomes turbid, and deposites a crystalline matter, consisting chiefly of gallic acid. During the change, oxygen is absorbed, and an equal volume of carbonic acid disengaged. Tannin has an affinity for acids, and when in solution affords precipitates with the sulphuric, nitric, muriatic, phosphoric, and arsenic acids, but not with the oxalic, tartaric, lactic, acetic, or citric. The precipitates are compounds of tannin with the respective acids, and are soluble in pure water, but insoluble in water with an excess of acid. Hence, in order to ensure precipitation, it is necessary to add the acid in excess to the solution of tannin. This principle also unites with most of the salifiable bases. With potassa it forms a compound but slightly soluble, and is therefore precipitated by this alkali or its carbonates from a solution which is not too dilute, though a certain excess of alkali will cause the precipitate to be redissolved. Its combination with soda is much more soluble; and this alkali affords no precipitate unless with a very concentrated solution of tannin. With ammonia its relations are similar to those with potassa. Baryta, strontia, lime, and magnesia, added in the state of hydrates, form with it compounds of little solubility. The same is the case with most of the metallic oxides, when presented, in the state of salts, to a solution of the tannate of potassa. Many of the metallic salts are precipitated by tannin even in the uncombined state, especially those of lead, copper, silver, uranium, chromium, mercury, and the protosalts of tin. With the persalts of iron it forms a black precipitate, which is a compound of tannin and the peroxide of iron, and is the basis of ink. It does not disturb the solutions of the pure protosalts of iron. Several of the alkaline salts precipitate tannin from its aqueous solution, either by the formation of insoluble compounds, or by simply abstracting the solvent. Tannin unites with all the vegetable alkalies, forming compounds which are for the most part of a whitish colour and but very slightly soluble in water, though they are soluble in the vegetable acids and in alcohol, and in this latter respect differ from most of the compounds which tannin forms with other vegetable principles. It precipitates solutions of starch, albumen, and gluten, and forms with gelatin, an insoluble compound, which is the basis of leather. Its ultimate constituents are carbon, hydrogen, and oxygen.

Medical Properties and Uses. Tannin, being the chief active principle of vegetable astringents, is capable of exerting on the system the same effects with this class of medicines, and may be given in the same complaints. It has an advantage over the astringent extracts in the comparative smallness of its dose, which renders it less apt to offend an irritable stomach. In most of the vegetable astringents, the tannin is associated with more or less bitter extractive, or other principle which modifies its operation, and renders the medicine less applicable than it otherwise would be, to certain cases in which there is an indication for pure astringency without any tonic power. Such is particularly the case with the active hemorrhages; and tannin, in its separate state, is in these cases preferable to the native combinations in which it ordinarily exists. Dr. Porta, an Italian physician, employed it with great success in the treatment of uterine hemorrhage, and published the results of his experience in 1827. M. Cavalier afterwards used it successfully in the same complaint, and found it effectual also in a case of bleeding from the rectum. There is no doubt that it would be found a highly useful remedy in most forms of hemorrhage, after a sufficient reduction of arterial action by depletory measures. In diarrhœa also it would probably be more beneficial than ordinary astringents, as less liable to irritate the stomach and bowels. It was given by Porta in the dose of three grains every three hours.

TEA. The plant which furnishes tea—*Thea Chinensis*—is an evergreen shrub, belonging to the class and order Monadelphia Polyandria of the Sexual system, (Polyandria Monogynia, *Linn.*) and to the natural order Ternströmiaceæ. It is usually from four to eight feet high, though capable, in a favorable situation, of attaining the height of thirty feet. It has numerous alternate branches, furnished with elliptical oblong or lanceolate, pointed leaves, which are serrate except at the base, smooth on both sides, green, shining, marked with one rib and many transverse veins, and supported alternately upon short footstalks. They are two or three inches long, and from half an inch to an inch in breadth. The flowers are either solitary, or supported two or three together at the axils of the leaves. They are of considerable size, not unlike those of the myrtle in appearance, consisting of a short green calyx with five or six lobes, of a corolla with from four to nine large unequal snow-white petals, of numerous stamens with yellow anthers and connected at their base, and of a pistil with a three-parted style. The fruit is a three-celled and three seeded capsule. It has not been certainly determined whether more than one species of the tea-plant exists. Linnæus admitted two species—the *T. Bohea* and the *T. viridis*—differing in the number of their petals; but this ground of distinction is untenable, as the petals are known to vary very much in the same plant. Hayne makes three species—the *T. stricta*, *T. Bohea*, and *T. viridis*, which are distinguished severally by the shape of their leaves and fruit, and the direction of the footstalk. Botanists, however, at present, generally agree with De Candolle in admitting but one species, with two varieties—the *viridis* or green tea, with "lanceolate flat leaves, three times as long as they are broad," and the *Bohea*, with elliptical oblong, subrugose leaves, twice as long as broad."

The tea-plant is a native of China and Japan, and is cultivated in both countries, but most abundantly in the former. In Japan it forms hedge rows around the rice and corn-fields; in China, whence immense quantities of tea are exported, whole fields are devoted to its culture. It is propagated from the seeds, which are planted in holes at certain distances apart, six or eight seeds being placed in each hole, in order to ensure the growth of one. In three years the plant yields leaves for collection, and in six years attains the height of a man. When from seven to ten years old, it is cut down, in order that the numerous shoots which issue from the stump may afford a large product of leaves. These are picked separately by the hand. Three harvests, according to Kœmpfer, are usually made during the year, the first at the end of February, the second at the beginning of April, and the third in June. As the youngest leaves are the best, the product of the first collection is most valuable, while that of the third, consisting of the oldest leaves, is comparatively little esteemed. Sometimes only one or two harvests are made; but care is always taken to assort the leaves according to their age; and thus originate numerous commercial varieties of tea. The character of the plant, dependent upon the soil, situation, climate, and culture, has also great influence upon the value of the leaves. It is said that the best tea is procured from the shrubs which grow upon the sides of steep hills with a southern exposure. Though the plant grows both about Pekin in the North, and Canton in the South of China, it is said to attain greater perfection in the intermediate country, in the neighbourhood of Nankin for instance, where the climate is neither so cold as in the first mentioned vicinity, nor so hot as in the second. Some of the commercial varieties have their origin in this cause; and it is not impossible, though the fact has not been ascertained, that difference in species may be another source of diversity in the product. After having been gathered, the leaves are dried by artificial heat in shallow iron pans, from which they are removed while still hot, and rolled with the fingers, or in the palm of the hand, so as to be brought into the form in which they are found in commerce. It is stated that the odour of the tea leaves themselves is very slight; and that it is customary to mix with them the leaves of certain aromatic plants, such as the *Olea fragrans* and *Camellia Sasanqua*, in order to render them pleasant to the smell. It is obvious that the nature of the addition will affect to a certain extent the quality of the tea, and thus still further increase the diversity arising from the age of the leaf and the character of the plant.

Tea is brought to this country from the port of Canton. Numerous varieties exist in commerce, differing in the shape communicated by rolling, in colour, in flavour, or in strength; but they may all be arranged in the two divisions of *green* and *black teas*, which, at least in their extremes, differ so much in properties, that it is difficult to conceive that they are derived from the same species.

Properties. Green tea is characterized by a dark-green colour, sometimes inclining more or less to blue or brown. It has a peculiar, refreshing, somewhat aromatic odour, and an astringent, slightly pungent, and agreeably bitterish taste. Its infusion has a pale greenish-yellow colour, with the odour and taste of the leaves. Green tea, according to Cadet de Gassicourt, contains gallic acid, tannin, and bitter extractive. One hundred parts of it yielded to Frank, 34.6 parts of tannin, 5.9 of gum, 5.7 of gluten, and 51.3 of lignin, with 2.5 of volatile matters including loss. But the tannin of Frank includes all the substances taken by alcohol from the watery extract, and consequently contains all the extractive matter existing in tea. Davy found only 8.5 per cent. of tannin. The volatile principle, which is probably essential oil, is the most important ingredient, as it is to this that tea owes its peculiarly agreeable flavour, and probably the effects which it produces upon the nervous system. This principle, however, has not been so far isolated as to admit of an examination of its precise nature. Frank found that tea, when distilled with water, lost all its odour, and that the product exhibited traces of volatile oil. There can be no doubt that the proportion of the ingredients of green tea is somewhat different in the different varieties.

Black tea is distinguished by a dark brown colour. It is usually less firmly rolled, and lighter than the green, and contains the petioles of the plant mingled with the leaves. Its odour is fainter and of a somewhat different character, though still fragrant. Its taste, like that of the green tea, is astringent and bitterish: but it is less pungent, and to most persons less agreeable. To hot water it imparts a brown colour, with its sensible properties of taste and smell. These vary exceedingly in strength in the different varieties; and some black teas are almost wholly destitute of aromatic or agreeable flavour. The constituents of black tea are of the same general character with those of the green. Frank found in 100 parts, 40.6 of tannin, 6.3 of gum, 6.3 of gluten, 44.8 of lignin, with 2.0 parts of volatile matter including loss. As in his analysis of green tea, the proportion of tannin is too largely stated. Davy found in Souchong tea, which is a variety of the black, only ten per cent. of tannin. There can be little doubt that black tea contains less volatile oil than green. The proportion of tannin would appear from the experiments of Frank and Davy to be greater; but the contrary is stated to have been the result of an examination by Brande of several varieties of each kind.

A crystallizable principle has been discovered in tea by Oudry, for which he proposes the name of *thëin.* To obtain it he infused 12½ parts of tea in 200 parts of cold water containing 3 parts of common salt. At the end of twenty-four hours he evaporated the infusion to dryness, treated the residue with alcohol of 0.81, again evaporated, dissolved the alcoholic extract in water, and digested the solution with pure magnesia. The solution filtered and concentrated, let fall crystals of *thëin.* This principle is colourless, soluble in water and alcohol, fusible, and, according to Oudry, capable of forming crystallizable compounds with sulphuric and citric acids, though it exhibits no alkaline reaction. Berzelius observes that these statements need confirmation. (*Berzelius, Traité de Chim.*)

Medical Properties and Uses. Tea is astringent and gently excitant, and in its finer varieties exerts a decided influence over the nervous system, evinced by the feelings of comfort and even exhilaration which it produces, and the unnatural wakefulness to which it gives rise when taken in unusual quantities, or by those unaccustomed to its use. Its properties, however, are not of so decided a character as to render it capable of very extensive application as a medicine; and its almost exclusive use, as every one knows, is as a grateful beverage at the evening and morning meal. Taken moderately, and by healthy individuals, it may be considered as perfectly harmless; but long continued in excessive quantity, it is capable of inducing unpleasant nervous and dyspeptic symptoms, the necessary consequences of over excitement of the brain and stomach. Green tea is decidedly more injurious in these respects than black, and should be avoided by dyspeptic individuals, and by those whose nervous systems are peculiarly excitable. As a medicine, tea may sometimes be given advantageously in diarrhœa; and a strong infusion will often be found to relieve nervous headach. For the latter purpose green tea should be preferred. The mode of preparing tea for use is too well known to require description. An extract is made from it in China, which is said to be useful in fevers.

TEUCRIUM CHAMÆDRYS. *Germander. Chamædrys.* A small, didynamous, labiate, perennial, European plant, the leaves and tops of which have an agreeable aromatic odour, diminished by drying, and a bitter, somewhat astringent, aromatic, durable taste. They have been employed as a mild corroborant, in uterine, rheumatic, gouty, and scrofulous affections, and intermittent fevers; but are at present little used, and never in this country. Germander was an ingredient in the *Portland powder*, noted as a remedy in gout. This powder, according to the original prescription, consisted of equal parts of the roots of the *Aristolochia rotunda* and *Gentiana lutea*, of the tops and leaves of the *Teucrium Chamædrys* and *Erythræa Centaurium*, and of the leaves of the *Ajuga Chamæpytis* or *ground pine*. The dose was a drachm taken every morning before breakfast, and continued for three months, then two scruples for three months, afterwards half a drachm for six months, and finally half a drachm every other day for a year. (*Farr.*)

Two other species of Teucrium have been used in medicine—the *T. Marum*, *cat thyme*, or *Syrian herb mastich*, which is a native of the South of Europe, and the *T. Scordium*, or *water germander*, which grows in the higher latitudes of the same continent. The former is a warm, stimulating, aromatic bitter, and has been highly recommended in hysteria, amenorrhœa, and cases of nervous debility; the latter has the odour of garlic, and a bitter somewhat pungent taste, and was formerly highly esteemed as a corroborant in low forms of disease; but neither of them is now much employed. The *T. Marum* is errhine, and was formerly an ingredient in the *Pulvis Asari Compositus*. The dose of either of the three species of Teucrium is about half a drachm.

THUJA OCCIDENTALIS. *Arbor Vitæ.* A small indigenous evergreen tree, growing wild from Canada to Carolina, and cultivated for ornament in gardens. The leaves, or small twigs invested with the leaves, are the part used. They have an agreeable balsamic odour, especially when rubbed, and a strong balsamic, camphorous, bitter taste. In the state of decoction, they have been used in intermittent fever, and according to Schoepf, in coughs, fevers, scurvy, and rheumatism. Made into an ointment with lard or other animal fat, they are said to form a useful local application in rheumatic complaints. The distilled water is praised by Boerhaave as a remedy in dropsy. (*Schoepf.*) A yellowish-green volatile oil, which may be obtained from the leaves by distillation, has been used with success in worms.

THYMUS VULGARIS. *Thyme.* A small well known undershrub, indigenous in the South of Europe, and with us cultivated in gardens. The herbaceous portion, which should be gathered when the plant is in flower, has a peculiar, strong, aromatic, agreeable odour, which is not lost by drying, and a pungent, aromatic, camphorous taste. Its active constituent is a volatile oil, which may be separated by distillation. Oil of thyme (*oleum thymi*) is, when fresh, of a pale yellow or greenish colour, but as found in the shops is often brown. Its sp. gr. is 0.905. The plant has the aromatic properties of sage, lavender, &c., and may be used for the same purposes. It is, however, more employed in cookery than in medicine. The *T. Serpillum*, or *wild thyme* of Europe, is analogous in properties to the garden thyme. Both are occasionally used in baths, fomentations, and poultices, along with other aromatic herbs.

TONKA BEAN. The seed of the *Dipterix odorata* of Willd., the *Coumarouna odorata* of Aublet, a large tree growing in Guiana. The fruit is an oblong-ovate pod, enclosing a single seed, from an inch to an inch and a half long, from two to four lines broad, usually somewhat compressed, with a dark-brown, wrinkled, shining, thin and brittle skin, and a light-brown, oily kernel. The bean has a strong, agreeable, aromatic odour, and a bitterish, aromatic taste. Its active constituent is a crystallizable, odorous substance, analogous to the volatile oils and camphor, and called *coumarin* by Guibourt. This substance is sometimes found in a crystalline state, between the two lobes of the kernel. The tonka bean is used to flavour snuff, being either mixed with it in the state of powder, or put entire into the snuff-box.

TRIGONELLA FŒNUMGRÆCUM. *Fenugreek.* An annual plant, growing spontaneously in different parts of the South of Europe, and cultivated in France and Germany for the sake of its seeds. These are one or two lines in length, oblong cylindrical, somewhat compressed, obliquely truncated at each extremity, brownish-yellow externally, yellow internally, and marked with an oblique furrow running half their length. They have a strong peculiar odour, and an oily, bitterish, farinaceous taste, and contain fixed and volatile oil, mucilage, bitter extractive, and a yellow colouring substance. An ounce of the seeds boiled in a pint of water renders it thick and slimy. They give out the whole of their distinguishing odour and taste to alcohol. Their virtues depend chiefly upon their oil and mucilage. On the continent of Europe they are employed in the preparation of emollient cataplasms and enemata, and enter into the composition of some officinal ointments and plasters. They are never used internally.

TRIPOLI. *Terra Tripolitana.* An earthy mineral, of a whitish, yellowish, or pale straw colour, sometimes inclining to red or brown, usually friable, often adhesive to the tongue, and presenting the aspect of argillaceous earth, though differing from clay by the roughness and hardness of its particles, and by not forming a paste with water. The *Venice tripoli* is said to come from the island of Corfu. Tripoli is sometimes artificially prepared by calcining certain argillites. It is used for cleaning and polishing metals.

TRITICUM REPENS. *Couch-grass. Dog-grass. Quickens.* A perennial European plant, very common in gardens and cultivated grounds, where it is considered a troublesome weed. The root, which is the part medically used, is horizontal, creeping, jointed, about as thick as a straw or thicker, inodorous, and of an agreeable, sweetish, slightly pungent taste. It is used in some parts of Europe, in the form of decoction, as a slightly aperient and nutritive drink. Great quantities of it are said to be consumed in the hospitals of Paris. The decoction, in consequence of the sugar which it contains, is susceptible of the vinous fermentation.

UMBER. *Terra Umbria.* A mineral, of a fine compact texture, light, dry to the touch, shining when rubbed by the nail, and of a fine pale brown colour, which changes to a peculiar beautiful deep brown by heat. According to Klaproth, it contains 13 parts of silica, 5 of alumina, 48 of oxide of iron, 20 of manganese, and 14 of water in 100. *Burnt umber,* as well as the mineral in its unaltered state, is used in painting. The umber of commerce is said to be brought chiefly from the island of Cyprus.

URTICA DIOICA. *Common nettle.* A well known perennial herbaceous plant, growing both in Europe and the United States, by the roadsides, in hedges, and gardens. The leaves, seeds, and roots, were formerly officinal. They were deemed diuretic and astringent, and were employed in nephritic complaints, hemorrhages, consumption, jaundice, worms, &c. The young shoots are boiled and eaten by the common people as a remedy in scurvy; and the fresh plant is sometimes used to excite external irritation in cases of torpor and local palsy, the part being beaten with it till the requisite degree of action is produced. The *U. urens* or *dwarf nettle*, which is an annual plant, and smaller than the former species, has similar properties, and is used for the same purposes. This species also grows wild both in America and Europe. The two plants were formerly distinguished by the names of *urtica major*, applied to the *U. dioica*, and of *urtica minor*, applied to the *U. urens.*

VANILLA. This is the fruit of the *Vanilla aromatica* of Schwartz, the *Epidendrum Vanilla* of Linn., a climbing plant, growing in the West Indies, Mexico, and South America. The pods are collected before they are quite ripe, dried in the shade, covered over with a coat of fixed oil, and then tied in bundles, which are surrounded with sheet lead, or enclosed in small metallic boxes, and sent into the market. Several varieties of vanilla exist in commerce. The most valuable, called *ley* by the Spaniards, consists of cylindrical, somewhat flattened pods, six or eight inches long, three or four lines thick, nearly straight; narrowing towards the extremities, bent at the base, shining and dark-brown externally, wrinkled longitudinally, soft and flexible, and containing within its tough shell, a soft, black pulp, in which numerous minute, black, glossy seeds are embedded. It has a peculiar, strong, agreeable odour, bearing some resemblance to that of balsam of Peru, and a warm, aromatic, sweetish taste. The interior pulpy portion is most aromatic. Another variety, called *simarona* by the Spaniards, is smaller, of a lighter colour, and less aromatic. A third variety is the *pomprona* of the Spaniards. In this, the pods are from five to seven inches long, from six to nine lines broad, almost always open, brown, soft, viscid, and of a strong odour, but less pleasant than that of the *ley*, to which it is considered inferior. According to Bucholz, vanilla does not yield volatile oil when distilled with water. It is employed to flavour chololate, ice-cream, &c., and as a perfume.

VENETIAN RED. *Bolus Veneta.* A dull-red ochrey substance used in painting.

VERBENA OFFICINALIS. *Vervain.* This is a common European weed, growing on the roadsides, in the vicinity of towns and villages. Its sensible properties do not indicate the possession of medical virtues; as it is nearly inodorous, and has only a slightly astringent bitterish taste. By the ancients it was highly esteemed both as a remedy in disease, and as a sacred plant employed in the performance of religious rites. In modern times, superstitious notions in relation to its virtues are still entertained; and the suspension of the root around the neck by a white ribband, has been gravely recommended for the cure of scrofula. The leaves, bruised, and applied in the form of a cataplasm, are used by the vulgar as a remedy in severe headach, and other local pains. The plant, however, is probably inert. An American species, the *V. hastata*, is more bitter than the European, and is said to be emetic. It is not, however, used in regular medical practice. Schoepf states that the root of the *V. urticifolia*, another indigenous species, has been advantageously used in cases of poisoning from the Rhus Toxicodendron. It is prepared by boiling it in milk and water along with the inner bark of the white oak.

VERDITER. Two preparations of copper, employed as pigments, are known by this name in commerce, and are distinguished by the epithets of blue and green. *Blue verditer* is prepared in London from the solution of nitrate of copper, obtained in precipitating silver by copper. According to Gray, this solution is poured hot upon whiting (carbonate of lime), and the mixture stirred every day till the liquor loses its colour, when it is decanted, and fresh portions added till the proper colour is obtained. By a process for procuring this pigment, invented by Pelletier, the solution of nitrate of copper is decomposed by quicklime, and the precipitate, after being washed, is incorporated intimately with another portion of quicklime. By the former process, a carbonate of copper is obtained, by the latter a mixture of the hydrated oxide of copper and hydrate of lime. *Green verditer* is prepared by precipitating a solution of nitrate of copper by chalk or a white marl, and consists of carbonate of copper mixed with an excess of the calcareous carbonate.

VISCUM ALBUM. *Misletoe.* A European evergreen parasitic shrub, growing on various trees, particularly the apple and other fruit trees, and forming a pendent bush from two to five feet in diameter. The plant is famous in the history of druidical superstition. In the religious rites of the druids, the misletoe of the oak was employed, and hence was afterwards preferred when the plant came to be used as a remedy; but it is in fact identical in all respects with those which grow upon other trees. The fresh bark and leaves have a peculiar disagreeable odour, and a nauseous, sweetish, slightly bitter taste. The berries, which are white, and of about the size of a pea, abound in a peculiar viscid principle, and are sometimes used in the preparation of birdlime, of which this principle is the basis. At one time the misletoe was highly esteemed as a remedy in epilepsy, palsy, and other nervous diseases; but it is now out of use. The leaves and wood were given in the dose of a drachm in substance, and of an ounce in decoction. Several species of Viscum grow in the United States, but are not used.

WHITING. This is essentially the same with the prepared carbonate of lime (prepared chalk) of the Pharmacopœias, being made by the pulverization and elutriation of crude chalk. It is used as a coarse paint, and for various purposes in the arts, for which carbonate of lime is requisite. *Paris white* is a variety of the same material.

ZEA MAYS. *Indian Corn.* Common Indian corn contains, according to the late Dr. Gorham, of Boston, 77 per cent. of starch, 3 of a principle analogous to gluten, called *zein*, 2.5 of albumen, 1.45 of sugar, 0.8 of extractive, 1.75 of gum, 1.5 of sulphate and phosphate of lime, 3 of lignin, and 9 of water. The meal, in the form of mush, makes an excellent emollient poultice, much used in hospitals; and a gruel may be prepared from it which is sometimes more grateful to the sick than that made from oat-meal.

ZEDOARY. *Radix Zedoariæ.* There are two kinds of zedoary, the long and the round, distinguished by the officinal titles of *radix zedoariæ longæ*, and *radix zedoariæ rotundæ*, the former produced by the *Curcuma Zedoaria* of Roxburgh, the latter, as some suppose, by the *Kæmpferia rotunda* of Linn.; but according to others, by the *Curcuma Zerumbet* of Roxburgh. Both kinds come from the East Indies. The *long zedoary* is in slices from an inch and a half to three inches in length, and from half an inch to an inch thick, obtuse at the extremities, and exhibiting the remains of the radical fibres; the *round* is also usually in slices, which are the sections of a roundish root, ending in a point beneath, and divided longitudinally into two parts, each of which is flat on one side, convex on the other, and heart-shaped in its outline. Sometimes the root of the latter variety is entire, and sometimes in quarters instead of halves. It is marked with circular rings on the convex surface, and, like the former, with small projecting points which are the remains of radical fibres. Both are grayish-white on the outside, yellowish-brown within, hard, compact, of an agreeable, aromatic odour, and a bitterish, pungent, camphorous taste. The round, however, is less spicy than the long. They yield a volatile oil when distilled with water.

Zedoary is a warm, stimulating aromatic, useful in flatulent colic and debilitated states of the digestive organs. It is not now employed, as it produces no effects which cannot be as well or better obtained from ginger. The dose is from ten grains to half a drachm.

ZERUMBET. *Cassumuniar.* Under these names an East India root was formerly used, having some analogy in sensible and medical properties to ginger, and ascribed to the *Zingiber Zerumbet* of Roscoe. Some consider the cassumuniar as a distinct root, and refer it to the *Zingiber Cassumuniar* of Roxburgh. The difference of opinion is of little importance, as neither of the roots, supposing them not to be the same, is at present to be found in the markets. By some authors the zerumbet has been erroneously confounded with the round zedoary. Geiger describes it as in pieces of the size of a fig or larger, externally grayish-brown and wrinkled, internally yellowish, hard, and tough, of a biting aromatic taste, and a spicy odour.

ZIZYPHUS VULGARIS, Lamarck. *Rhamnus Zizyphus*, Linn. A shrub, or small tree, growing in the countries bordering on the Mediterranean, and cultivated in Italy, Spain, and the South of France. The fruit is the part used. This consists of oval drupes, of the size of a large olive, with a thin, coriaceous, red or reddish-brown skin, a yellowish, sweet, acidulous pulp, and an oblong pointed stone in the centre. These have the officinal name of *jujubæ*. By drying, their pulp becomes softer and sweeter, and acquires a vinous taste, evincing the commencement of fermentation. They are nutritive and demulcent, and are used in the form of decoction in pectoral complaints. *Jujube paste* consists, properly, of gum Arabic and sugar, dissolved in a decoction of this fruit, and evaporated to the proper consistence. As a demulcent, it is in no respect superior to a paste made with gum Arabic and sugar alone, and the preparation commonly sold in this country under the name, contains in fact none of the fruit.

The fruits of two other species of Zizyphus, the *Z. Lotus*, growing in the North of Africa, and the *Z. Jujuba*, a native of the East Indies, possess properties similar to those of the first mentioned species, and are used as food by the inhabitants of the countries where they grow.

NOTE.—Of the articles included in the foregoing list, those upon *Acetic Ether, Bromine, Cheltenham Salt, Chloride of Lime, Chloride of Potassa, Chloride of Soda, Chlorine Ethers, Creosote, Cyanuret of Potassium, Cyanuret of Zinc, Dippel's Animal Oil, Ferrocyanate of Potassa, Gold, Iodide of Ammonium, Iodide of Iron, Iodide of Sulphur, Iodide of Zinc, Iodo-hydrargyrate of Potassium, Muriatic Ether, Artificial Musk, Nitrate of Soda, Oxalic Acid, Phosphorus,* and *Soot* were written by Dr. Bache; the remainder by Dr. Wood.

[illegible] Dispensatory

II. ART OF PRESCRIBING MEDICINES.

The physician should be acquainted not only with the properties of medicines, and the diseases to which they are respectively applicable, but also with the art of prescribing them, so that they may be adapted to the peculiarities of individual patients, and, by the mode in which they are administered, may produce the greatest curative effect with the least possible inconvenience. In relation to these points, a few general rules will be useful for the guidance of the young practitioner, although much must be left to his own judgment and discretion. We shall compress the remarks which we have to offer, under the two heads of the quantity or dose in which medicines may be given, and the mode of their exhibition.

1. Dose of Medicines.—In the body of the work, the quantity has been stated in which each medicine must ordinarily be given to produce its peculiar effects in the adult patient. But there are various circumstances which modify the dose, and demand attention on the part of the practitioner.

The *age* of the patient is the most important of these circumstances. The young require a smaller dose than those at maturity, to produce an equal effect; and the old, though their systems are, perhaps, less susceptible to the action of medicines than those of the middle-aged, cannot bear an equally forcible impression. The following table of Gaubius, exhibiting the doses proportioned to the age, is frequently referred to.

The dose for a person of middle age being	1	or	1 drachm,
That of a person from 14 to 21 years will be	$\frac{2}{3}$	or	2 scruples,
7 to 14 " "	$\frac{1}{2}$	or	$\frac{1}{2}$ a drachm,
4 to 7 " "	$\frac{1}{3}$	or	1 scruple,
of 4 years "	$\frac{1}{4}$	or	15 grains,
3 " "	$\frac{1}{6}$	or	10 grains,
2 " "	$\frac{1}{8}$	or	8 grains,
1 " "	$\frac{1}{12}$	or	5 grains.

We prefer the following simple scheme of Dr. Young, which we extract from Paris's Pharmacologia.

"For children under twelve years, the doses of most medicines must be diminished in the proportion of the age to the age increased by 12; thus at two years to $\frac{1}{7}$—viz. $\frac{2}{2+12}=\frac{1}{7}$. At twenty-one the full dose may be given."

To the above rule some exceptions are offered in particular medicines, which require to be given to children in much larger proportional doses than those above stated. Such are castor oil and calomel, a certain quantity of which will in general not produce a greater effect in a child two or three years old than double the quantity in an adult.

Sex, temperament, and *idiosyncrasy* have also an influence upon the dose, and should be kept in view in prescribing. Females usually require somewhat smaller doses than males, and those of sanguine temperament than the phlegmatic. Constitutional peculiarities, called idiosyncrasies, often exist in individuals, rendering them more than usually susceptible or insusceptible to the action of certain remedies, the dose of which must be modified accordingly. Thus in some persons a grain or two of calomel will excite salivation, while in others scarcely any quantity which can be safely administered will produce this effect. Sometimes, moreover, a medicine operates on an individual in a manner wholly different from its ordinary mode. In all such cases experience is the only sure guide; but the occasional existence of these peculiarities indicates the propriety of making particular inquiries in relation to the idiosyncrasies of those patients, for whom we may be called for the first time to prescribe.

Habit is another important circumstance which modifies the dose of medicines. Generally speaking, the susceptibility to the action of medicines is diminished by their frequent and continued use; and in order to maintain a given impression, the quantity must be regularly increased. This is especially true in regard to the narcotics, which are sometimes borne in enormous doses by those habituated to their use. It is a good practical rule in prescribing, when circumstances demand the continuance, for a considerable length of time, of some particular effect, to vary the medicine, and employ successively several of the same general powers, so as not too rapidly to exhaust the susceptibility to the action of any individual remedy. Another important practical rule connected with the influence of habit, is, when any medicine, which from its nature is of variable strength, has been employed for some time in increasing doses, to reduce the dose upon resorting to a new parcel, until its relative strength has been ascertained. A neglect of this precaution, in cases where the last parcel happened to be more powerful than that previously employed, has sometimes been followed by very serious consequences.

2. MODE OF ADMINISTERING MEDICINES.—This has reference both to the combination of medicines with one another, and the form in which they are exhibited.

Simplicity in prescription is always desirable when no object is to be gained by deviating from it. Remedies should never be mixed together without a definite purpose, nor with the vague hope that out of the number prescribed some one may perchance produce a salutary impression. Those exceedingly complex prescriptions, formerly so much in vogue, of which the ingredients were so numerous as to render altogether impossible a reasonable estimate of their bearing on each other, or their effects on disease, have been generally abandoned by modern practitioners. The only ground upon which any of them can be justifiably retained, is, that by very frequent trials, through a long course of years, and in various states of disease, their influence on the system may have been fully ascertained, so that they may be considered rather in the light of a single remedy than a compound of many. Upon this ground, however, no prudent physician would attempt to originate such combinations. In mixing medicines, he would proceed no further than he would be justified in doing by a clear knowledge of the properties and mutual relations of the several ingredients, and their fitness to answer some decided indication in the treatment of disease. There are certain principles upon which medicines may be advantageously combined, and which it may not be amiss to mention for the benefit of the young practitioner.

Remedies of the same general character may be given in connexion, in order to increase their energy, or to render their action more certain. It has been well ascertained, that substances thus combined will often act vigorously, when severally they would produce comparatively little effect; and it sometimes happens, that while their activity is augmented, they are at the same time rendered less irritating, as in the case of the drastic cathartics. (See *Pilulæ Catharticæ Compositæ.*)

Different medicines are very often mixed together, in order to meet different and coexisting indications, without any reference to the influence which they may reciprocally exert on each other. Thus in the same patient we not unfrequently meet with debility of stomach and constipation of the bowels, connected with derangement of the hepatic function. To answer the indications presented by these morbid conditions, we may properly combine in the same dose, a tonic, cathartic, and mercurial alterative. For similar reasons we often unite tonics. purgatives, and emmenagogues, anodynes and diaphoretics, emetics and cathartics, antacids, astringents, and tonics; and scarcely two medicines can be mentioned, not absolutely incompatible with each other, which may not occasionally be combined with advantage to counteract coexisting morbid actions.

Another very important object of combination, is the modification which is thereby effected in the actions of medicines differing from each other in properties. In this way new powers are sometimes developed, and those previously existing are greatly increased. Examples of such a result are afforded in the officinal powder of ipecacuanha and opium, and in the combination of squill and calomel; the former operating as a diaphoretic, the latter as a diuretic, beyond the capabilities of either of their constituents. The effects of one medicine are, in numerous instances, increased by the influence of another in augmenting the natural susceptibility of the system to its action. Thus bitters enable cathartics to operate in smaller doses; purgatives awaken the dormant susceptibility to the action of mercury; and stimulants excite the torpid stomach, so that it will receive impressions from various medicines before inoperative. In some instances, the action of one medicine is promoted by that of another apparently of a nature wholly opposite. Thus, when calomel and opium are given in colic, the purgative operation of the former is facilitated by the relaxation of intestinal spasm produced by the latter. Medicines, in addition to the effects for which they are administered, very frequently produce disagreeable symptoms, which may be moderated or altogether prevented by combination with other medicines; and this object may usually be accomplished, without in the least degree interfering with the remediate influence desired. Thus the griping produced by cathartics, and the nausea by these and various other medicines, may often be corrected by the stimultaneous use of aromatics. To cover the disagreeable taste or odour of certain medicines, and to afford a convenient vehicle for their administration, are also important objects of combination; as upon these circumstances often depend the acceptability of the medicine to the stomach, and even the possibility of inducing the patient to swallow it. Substances should be preferred as vehicles which are calculated to render the medicine acceptable to the palate and stomach, and in other ways to correct its disagreeable effects; as syrups for powders, the aromatic waters for medicines given in the form of mixture, and carbonic acid water for the neutral salts.

But in the mixing of medicines, care should be taken that they are neither chemically nor physiologically incompatible; in other words, that they are not such as will react on each other so as to produce new and unexpected combinations, nor such as will exert contrary and opposing effects upon the system. Thus when the operation of an acid is desired, an alkali should not be given at the same time, as they unite to form a third substance entirely different from either; nor should a soluble salt of lime, baryta, or lead, be given with sulphuric acid or a soluble sulphate, as decomposition would ensue, with the production of an inert compound. So also, in relation to physiological incompatibility, diaphoretics and diuretics should not, as a general rule, be united with a view to their respective effects; as these are to a certain extent incompatible, one being diminished by whatever has a tendency to increase the other. There are cases however, in which we may advantageously combine medicines with a view to their chemical reaction, as in the instance of the effervescing draught; and circumstances sometimes call for the union of remedies apparently opposite, as in the case of colic before alluded to, in which opium may be advantageously combined with purgatives. Still, such combinations should never be formed, unless with a full understanding of their effects, and a special reference to them.

The *form in which medicines are exhibited*, is often an object of considerable importance. By variation, in this respect, according to the nature of the medicine, the taste of the patient, or the condition of the stomach, we are frequently enabled to secure the favourable operation of remedies, which without such attention might prove useless or injurious. Medicines may be given in the solid state, as in the form of powder, pill, troche, or electuary; in the state of mixture, in which a solid is suspended in a liquid, or one liquid is mechanically mixed with another in which it is insoluble; or in the state of solution, under which may be included the various forms of infusion, decoction, tincture, wine, vinegar, syrup, honey, and oxymel. Of these different forms we have already treated sufficiently at large, under their respective heads, in the second part of this work.

In writing extemporaneous prescriptions, neatness, order, and precision, should always be observed; as, independently of the pleasing moral effect inseparable from these principles in all things, a positive practical advantage results, in the greater accuracy which the habit of attending to them gives to the prescriber, and the comparative certainty which they afford that his directions will be strictly complied with. As a general rule, when medicines are combined in prescription, that should come first in order which is considered as the most prominent and important, next the adjuvant or corrigent, and lastly the vehicle. Sometimes, however, it is important to indicate to the apothecary the succession in which the substances should be combined in reference to the perfection of the mixture, and this may render convenient a deviation from the order above mentioned. The physician should always be careful either to write out the full name of the medicine, or to employ such abbreviations as are not likely, by the misunderstanding of an ill-formed letter, to lead into error. Very serious and even fatal mistakes have been occasioned by a neglect of this precaution. The formulæ of the several Pharmacopœias which are detailed in this work, will serve as good examples for the guidance of the young practitioner. The following table explains the signs and abbreviations habitually used in prescription. The formulæ afterwards given will serve to illustrate the ordinary mode of prescribing, while they exhibit combinations of medicines frequently employed in practice. W.

Table of Signs and Abbreviations.

℞	Recipe.	Take.
āā	Ana.	Of each.
℔	Libra vel libræ.	A pound or pounds.
℥	Uncia vel unciæ.	An ounce or ounces.
ʒ	Drachma vel drachmæ.	A drachm or drachms.
℈	Scrupulus vel scrupuli.	A scruple or scruples.
O	Octarius vel octarii.	A pint or pints.
f℥	Fluiduncia vel fluidunciæ	A fluidounce or fluidounces.
fʒ	Fluidrachma vel fluidrachmæ.	A fluidrachm or fluidrachms.
♏	Minimum vel minima.	A minim or minims.
Chart.	Chartula vel Chartulæ.	A small paper or papers.
Coch.	Cochlear vel cochlearia.	A spoonful or spoonfuls.
Collyr.	Collyrium.	An eye-water.
Cong.	Congius vel Congii.	A gallon or gallons.
Decoct.	Decoctum.	A decoction.
Ft.	Fiat.	Make.
Garg.	Gargarysma.	A gargle.
Gr.	Granum vel Grana.	A grain or grains.
Gtt.	Gutta vel guttæ.	A drop or drops.
Haust.	Haustus.	A draught.
Infus.	Infusum.	An infusion.
M.	Misce.	Mix.
Mass.	Massa.	A mass.
Mist.	Mistura.	A mixture.
Pil.	Pilula vel pilulæ.	A pill or pills.
Pulv.	Pulvis vel pulveres.	A powder or powders.
Q. S.	Quantum sufficit.	A sufficient quantity.
S.	Signa.	Write.
Ss.	Semis.	A half.

Examples of Common Extemporaneous Prescriptions.

POWDERS.

℞ Antimonii et Potassæ Tartratis gr. i.
Pulveris Ipecacuanhæ ℈i.
Fiat pulvis.

S. To be taken in a wineglassful of sweetened water.

An active emetic.

℞ Hydrargyri Chloridi Mitis.
Pulveris Jalapæ āā gr. x.
Misce.

S. To be taken in syrup or molasses.

An excellent cathartic in the commencement of bilious fevers, and in hepatic congestion.

℞ Pulveris Jalapæ gr. x.
Potassæ Supertartratis ʒii.
Misce.

S. To be taken in syrup or molasses.

A hydragogue cathartic used in dropsy and scrofulous inflammation of the joints.

℞ Sulphuris ʒi.
Potassæ Supertartratis ʒii.
Misce.

S. To be taken in syrup or molasses.

A laxative, used in piles and cutaneous diseases.

℞ Pulveris Rhei gr. x.
Magnesiæ ʒss.
Fiat pulvis.

S. To be taken in syrup or molasses.

A laxative and antacid, used in diarrhœa, dyspepsia, &c.

℞ Pulveris Scillæ gr. xii.
Potassæ Nitratis ʒi.
Fiat Pulvis, in chartulas sex dividendus.

S. One to be taken twice or three times a day in syrup or molasses.

A diuretic employed in dropsy.

℞ Potassæ Nitratis ʒi.
Antimonii et Potassæ Tartratis gr. i.
Hydrarg. Chlorid. Mitis gr. vi.
Fiat pulvis, in chartulas sex dividendus.

S. One to be taken every two hours in syrup or molasses.

A refrigerant, diaphoretic, and alterative, used in bilious fevers; usually called *nitrous powders.*

℞ Pulveris Guaiaci.
Potassæ Nitratis āā ʒi.
Pulveris Ipecacuanhæ gr. iii.
Opii gr. ii.
Fiat pulvis, in chartulas sex dividendus.

S. One to be taken every three hours in syrup or molasses.

A stimulant diaphoretic, used in rheumatism and gout after sufficient depletion.

℞ Ferri Carbonatis Præcipitati,
Pulveris Colombæ,
Pulveris Zingiberis. ʒāāi.
Fiat pulvis, in chartulas sex dividendus.

S. One to be taken three times a day in syrup or molasses.

A tonic, used in dyspepsia and general debility.

PILLS.

℞ Pulveris Aloës,
Pulveris Rhei āā ʒss.
Saponis ℈i.
Misce, et cum aqua fiat massa in pilulas viginti dividenda.

S. Two or three to be taken daily at bed-time or before a meal.

An excellent laxative in habitual constipation.

℞ Massæ Pilularum Hydrargyri,
Pulveris Aloës,
Pulveris Rhei āā ℈i.
Misce, et cum aqua fiat massa in pilulas viginti dividenda.

S. Three to be taken at bed-time.

An alterative and laxative, useful in constipation with deranged or deficient hepatic secretion.

℞ Pulveris Aloës,
Extracti Quassiæ āā ʒi.
Olei Anisi ♏x.
Syrupi q. s.
Misce, et fiat massa in pilulas triginta dividenda.

S. Two to be taken once, twice, or three times a day.

A laxative, tonic, and carminative, useful in dyspepsia.

℞ Pulveris Scillæ ℈i.
Hydrargyri Chloridi Mitis gr. x.
Pulveris Acaciæ Gummi,
Syrupi āā q. s.
Misce, et fiat massa in pilulas decem dividenda.

S. One to be taken two or three times a day.

A diuretic and alterative, much used in dropsy, especially when complicated with organic visceral disease.

℞ Pulveris Opii gr. iv.
Pulveris Ipecacuanhæ gr. xviii.
Syrupi Acaciæ q. s.
Misce, et fiat massa in pilulas duodecim dividenda.

One to be taken after each stool.

An anodyne diaphoretic, useful in dysentery and diarrhœa after the use of laxatives.

℞ Pulveris Opii,
Pulveris Ipecacuanhæ āā gr. iii.
Hydrargyri Chloridi Mitis gr. vi.
Pulveris Acaciæ Gummi,
Syrupi āā q. s.
Misce, et fiat massa in pilulas tres dividenda.

S. One or more to be taken at bed-time, or according to circumstances.

An anodyne, diaphoretic, and alterative, very useful in diarrhœa, dysentery, typhoid pneumonia, and various other diseases.

℞. Plumbi Acetatis in pulverem triti gr. xii.
Pulveris Opii gr. i.
Pulv. Acaciæ Gummi,
Syrupi āā q. s. ut fiat massa in pilulas sex dividenda.

S. One every two, three or four hours.

An astringent much employed in hæmoptysis and uterine hemorrhage.

MIXTURES.

℞ Magnesiæ ʒi.
Syrupi f℥i.
Tere simul et affunde
Aquæ Acidi Carbonici f℥iv.
Fiat haustus.

S. To be taken at a draught, the mixture being well shaken.

An agreeable mode of administering magnesia.

℞ Mannæ ℥i.
Fœniculi contusi ʒi.
Aquæ bullientis f℥iv.
Fiat infusum et cola; dein adjice
Magnesiæ Carbonatis ʒii.
Ft. mist.

S. One third to be taken every three or four hours till it operates, the mixture being shaken.

An excellent carminative and mild laxative in flatulence and pain in the bowels.

℞ Olei Ricini f℥i.
Pulveris Acaciæ Gummi,
Sacchari āā ʒii.
Aquæ Menthæ Piperitæ f℥iii.
Gummi et saccharum cum fluiduncia dimidia aquæ menthæ tere; dein oleum adjice, et contere; denique aquam reliquam paulatim infunde, et omnia misce.

S. To be taken at a draught, the mixture being well shaken.

℞ Olei Ricini f℥i.
Vitellum ovi unius.
Tere simul et adde
Syrupi f℥ss.
AquæMenthæ Piperitæ f℥ii.
Ft. haust.

S. To be taken at a draught, the mixture being well shaken.

This and the preceding formula afford convenient modes of administering castor oil, when the stomach is irritable. Any other fixed oil may be given in the same way.

℞ Olei Ricini f℥iss.
Tincturæ Opii ♏xxx.
Pulv. Acaciæ Gummi,
Sacchari āā ʒii.
Aquæ Menthæ Viridis f℥iv.

Gummi et saccharum cum paululo aquæ menthæ tere; dein oleum adjice, [illegible] iterum tere; denique aquam reliquam paulatim infunde, et omnia misce.

S. A tablespoonful to be taken every hour or two hours till it operates, the mixture being each time well shaken.

Used as a gentle laxative in dysentery and diarrhœa. It is usually known by the name of *oleaginous mixture.*

℞ Elaterii gr. i.
Spiritûs Ætheris Nitrici f℥ii.
Tincturæ Scillæ,
Oxymellis Colchici āā f℥ss.
Syrupi f℥i.
Ft. mist.

S. A teaspoonful to be taken three or four times a day in a little water.

Diuretic, used by Ferriar in dropsy.

℞ Copaibæ,
Spiritûs Lavandulæ Comp. āā fʒii.
Mucilaginis Acaciæ f℥ss.
Syrupi fʒiii.
Simul tere; dein paulatim affunde
Aquæ f℥iv.
Misce.

S. A tablespoonful to be taken four times a day or more frequently.

Given in chronic catarrhs, and chronic nephritic affections. The dose must be larger in gonorrhœa.

Neutral Mixture.

℞ Acidi Citrici ʒii.
Olei Limonis ♏i.
Simul tere et adde
Aquæ f℥iv.
Liqua, et adde
Potassæ Carbonatis q. s. ad saturand.
Misce et per linteum cola.

Or

℞ Succi Limonis Recentis f℥iv.
Potassæ Carbonatis q. s. ad saturandum.
Misce et cola.

S. A tablespoonful to be given with an equal quantity of water every hour or two hours.

An excellent diaphoretic in fever.

Effervescing Draught.

℞ Potassæ Carbonatis ʒii.
Aquæ f℥iv.
Liqua.

Or

℞ Potassæ Bicarbonatis ʒiii.
Aquæ f℥iv.
Liqua.

S. Add a tablespoonful of the solution to the same quantity of lemon or lime juice, previously mixed with a tablespoonful of water; and give the mixture, in the state of effervescence, every hour or two hours.

An excellent diaphoretic and anti-emetic in fever with nausea or vomiting.

Brown Mixture.

℞ Pulv. Extract. Glycyrrhizæ,
Pulv. Acaciæ Gum. āā ʒii.
Aquæ ferventis f℥iv.
Liqua, et adde
Vini Antimonii fʒii.
Tincturæ Opii fʒss.
Ft. Mist.

S. A tablespoonful to be taken occasionally.

Expectorant, demulcent, and anodyne, useful in catarrhal affections.

℞ Antimonii et Potassæ Tartratis gr. i.
Syrupi Scillæ,
Liquoris Morphiæ Sulphatis āā f℥ss.
Syrupi Acaciæ f℥i.
Aquæ fluvialis f℥iv.
Ft. Mist.

S. A tablespoonful to be taken occasionally.

An expectorant and anodyne cough mixture.

℞ Acidi Nitrosi fʒi.
Tincturæ Opii gtt. xl.
Aquæ Camphoræ f℥viii.
Misce.

S. One-fourth to be taken every three or four hours.

Hope's mixture, used in dysentery, diarrhœa, and cholera.

℞ Camphoræ ʒi.
Myrrhæ ʒss.
Pulv. Acaciæ Gum.
Sacchari āā ʒii.
Aquæ f℥vi.

Camphoram cum alcoholis paululo in pulverem tere; dein cum myrrha, acaciæ gummi, et saccharo contere; denique cum aquâ paulatim instillatâ misce.

S. A tablespoonful to be taken for a dose, the mixture being well shaken.

A convenient form for administering camphor.

℞ Pulveris Kino ʒii.
Aquæ bullientis f℥vi.
Fiat infusum et cola; dein secundum artem admisce
Calcis Carbonatis Præparati ʒiii.
Tincturæ Opii fʒss.
Spiritûs Lavandulæ Compositi f℥ss.
Pulveris Acaciæ Gummi,
Sacchari āā ʒii.

S. A tablespoonful to be taken for a dose, the mixture being well shaken.

Astringent and antacid, useful in diarrhœa.

SOLUTIONS.

℞ Magnesiæ Sulphatis ℥i.
Syrupi Limonis f℥i.
Aquæ Acidi Carbonici f℥vi.
Misce.
S. To be taken at a draught.

An agreeable mode of administering the sulphate of magnesia.

℞ Potassæ Nitratis ʒi.
Antimonii et Potassæ Tartratis gr. i.
Aquæ fluvialis f℥iv.
Liqua.
S. A tablespoonful to be taken every two hours.

A refrigerant diaphoretic used in fevers.

℞ Magnesiæ Sulphatis ℥i.
Antimonii et Potassæ Tartratis gr. i.
Succi Limonis recentis f℥i.
Aquæ f℥iii.
Misce.
S. A tablespoonful to be taken every two hours till it operates upon the bowels.

Useful in fevers.

℞ Quiniæ Sulphatis gr. xii.
Acidi Sulphurici Aromatici ♏xx.
Syrupi f℥ss.
Aquæ Menthæ Piperitæ f℥i.
Misce.
S. A teaspoonful to be taken every hour or two hours.

A good mode of administering sulphate of quinia in solution.

INFUSIONS.

℞ Sennæ ʒiii.
Magnesiæ Sulphatis,
Mannæ āā ℥ss.
Fœniculi ʒi.
Aquæ bullientis Oss.
Macera per horam in vase leviter clauso et cola.
S. Give a teacupful every three or four hours till it operates.

An excellent purgative in febrile complaints.

℞ Colombæ contusæ,
Zingiberis contusi āā ℥ss.
Sennæ ʒii.
Aquæ bullientis Oi.
Macera per horam in vase leviter clauso et cola.
S. A wineglassful to be taken morning, noon, and evening, or less frequently if it operate too much.

An excellent remedy in dyspepsia with constipation and flatulence.

℞ Spigeliæ ℥ss.
Sennæ ʒii.
Mannæ ℥i.
Fœniculi ʒii.
Aquæ bullientis Oi.
Macera per horam in vase leviter clauso et cola.
S. A wineglassful to be given to a child from two to four years old, three or four times a day.

A powerful anthelmintic.

℞ Pulveris Cinchonæ Rubræ ℥i.
Acidi Sulphurici Aromatici fʒi.
Aquæ Oi.
Macera per horas duodecim, subinde agitans.
S. A wineglassful of the clear liquid to be taken for a dose.

A good method of administering Peruvian bark in cold infusion.

III. TABLES OF WEIGHTS AND MEASURES.

APOTHECARIES' WEIGHT. *U.S., Lond., Ed., Dub.*

Pound.		Ounces.		Drachms.		Scruples.		Grains.
℔ 1	=	12	=	96	=	288	=	5760
		℥ 1	=	8	=	24	=	480
				ʒ 1	=	3	=	60
						℈ 1	=	gr. 20

The Imperial Standard Troy weight at present recognised by the British laws, corresponds with the Apothecaries' weight in pounds, ounces, and grains, but differs from it in the division of the ounce, which, according to this scale, contains twenty pennyweights, each weighing twenty-four grains.

AVOIRDUPOIS WEIGHT.

Pound.		Ounces.		Drachms.		Troy grains.
℔ 1	=	16	=	256	=	7000
		oz. 1	=	16	=	437.5
				dr. 1	=	gr. 27.34375

Relative Value of Troy and Avoirdupois Weights.

Pound.		Pounds.		Pound.	Oz.	Grains.
1 Troy	=	0.822857 Avoirdupois	=	0	13	72.5
1 Avoirdupois	=	1.215277 Troy	=	1	2	280

APOTHECARIES' MEASURE. *U.S., Lond., Dub.*

Gallon.		Pints.		Fluidounces.		Fluidrachms.		Minims.		Cubic Inches.
Cong. 1	=	8	=	128	=	1024	=	61440	=	231

1 scruple	=			0	0	0	21.0667
1 grain	=			0	0	0	1.0533

2. Value of Apothecaries' Measure in Apothecaries' Weight.

				Pounds.	oz.	dr.	sc.	gr.		Grains.
1 gallon	=	10.12654270 pounds	=	10	1	4	0	8.88	=	58328.886
1 pint	=	1.26581783 pounds	=	1	3	1	1	11.11	=	7291.1107
1 fluidounce	=	0.94936332 ounces	=	0	0	7	1	18.69	=	455.6944
1 fluidrachm	=	0.94936332 drachms	=	0	0	0	2	16.96	=	56.9618
1 minim	=	0.94936332 grains	=							.9493

3. Value of Avoirdupois Weight in Apothecaries' Measure.

	Pints.	Fluidounces.	Fluidrachms.	Minims.
1 pound = 0.9600732 pints =	0	15	2	53.3622
1 ounce = 0.9600732 fluidounces =	0	0	7	40.8351

4. Value of Apothecaries' Measure in Avoirdupois Weight.

1 gallon = 8.33269800 pounds.
1 pint = 1.04158725 pounds.
1 fluidounce = 1.04158725 ounces.

In converting the weights of liquids heavier or lighter than water into measures, or conversely, a correction must be made for specific gravity. In converting weights into measures, the calculator may proceed as if the liquid was water, and the obtained measure will be to the true measure *inversely* as the specific gravity. In the converse operation, of turning measures into weights, the same assumption may be made, and the obtained weight will be to the true weight *directly* as the specific gravity.

FORMER FRENCH WEIGHTS.

——— French pounds (poids de Marc) into Troy pounds, multiply by ——— Troy pounds into French pounds, divide by	1.31268

FRENCH DECIMAL WEIGHTS AND MEASURES.

The French metrical system is based upon the idea of employing, as the unity of all measures, whether of length, capacity, or weight, a uniform, unchangeable standard, adopted from nature, the multiples and subdivisions of which should follow in decimal progression. To obtain such a standard, the length of one-fourth part of the terrestrial meridian, extending from the equator to the pole, was ascertained. The ten millionth part of this arc was chosen as the unity of measures of length, and was denominated *metre.* The cube of the tenth part of the metre was taken as the unity of measures of capacity, and denominated *litre.* The weight of distilled water, at its greatest density, which this cube is capable of containing, was called *kilogramme,* of which the thousandth part was adopted as the unity of weight, under the name of *gramme.* The multiples of these measures, proceeding in the decimal progression, are distinguished by employing the prefixes *deca, hecto, kilo,* and *myria,* taken from the Greek numerals; and the subdivisions, following the same order, by *deci, centi, mili,* from the Latin numerals.

The *metre,* or unity of length, at 32°	=	39.371	English inches at 62°.
The *litre,* or unity of capacity,	=	61.028	English cubic inches.
The *gramme,* or unity of weight,	=	15.44402	Troy grains.

Upon this basis the following tables, which we take with some slight alterations from the Edinburgh New Dispensatory, have been constructed; but it has been ascertained by accurate examination at the London Mint, that the gramme is only 15.434 Troy grains instead of 15.444 as above stated.

MEASURES OF LENGTH.

The metre being at 32°, and the foot at 62°.

		English Inches.		Miles.	Fur.	Yards.	Feet.	Inches.

Kilogramme	=	15444.0234	=	2	8	1	24.
Myriagramme	=	154440.2344	=	26	9	6	0

Though the decimal system of weights and measures was established by law in France, it was found impossible to procure its general adoption by the people, who obstinately adhered to the old *poids de marc* and its divisions, or, if they adopted the new weights, gave them the names of the old weights to which they most nearly approached. Thus the *kilogramme*, which is equal to 18,827 $\frac{15}{100}$ French grains, or 2 pounds 5 gros 35 $\frac{15}{100}$ grains *poids de marc*, was divided into two parts, and the half of it called a pound. One reason for this adherence to the old weights was the convenience of division into halves, quarters, &c., of which the new were not susceptible. To obviate this difficulty, the imperial government legalized the employment of the half kilogramme as the unity of weight, under the name of pound, and allowed this to be divided into half pounds, quarters, eighths, ounces; &c., as in the old *poids de marc*. The new pound is distinguished by the name of *metrical pound*, and has been adopted to a considerable extent; while the old weights are retained by some, particularly by the apothecaries and goldsmiths; so that three systems are now more or less in use in France—the original *poids de marc*, the decimal system, and the metrical pound with its divisions. The following table represents the relative value of these different weights.

Decimal System.		Poids de Marc.					Metrical Pound.			
		℔	oz.	dr.	gr.		℔	oz.	dr.	gr.
1 centigramme	=	0	0	0	0.19	=	0	0	0	0.18
1 decigramme	=	0	0	0	1.88	=	0	0	0	1.84
1 gramme	=	0	0	0	18.83	=	0	0	0	18.43
1 decagramme	=	0	0	2	44.27	=	0	0	2	40.32
1 hectogramme	=	0	3	2	10.71	=	0	3	1	43.2
1 kilogramme	=	2	0	5	35.15	=	2	0	0	0

Poids de Marc.		Grammes.	Metrical Pound.		Grammes.
1 grain	=	0.0531	1 grain	=	0.054
24 grains or ℈i	=	1.2747	24 grains or ℈i	=	1.302
72 grains or ʒi	=	3.8242	72 grains or ʒi	=	3.906
1 ounce	=	30.5941	1 ounce	=	31.25
1 pound	=	489.5058	1 pound	=	500.00

The following table was calculated from one in the Edinburgh New Dispensatory, in which the several weights are given in milligrammes, on the authority of Meissner, Nelkenbrecher, and Otto. It is evident that the milligrammes, by a successive division by the number 10, may be converted into the higher denominations of the French decimal weights. In these calculations the gramme is considered as equivalent to 15.44402 Troy grains.

Table of certain foreign Apothecaries' weights, exhibiting the value of a pound in milligrammes and Troy grains.

Pound.		Milligrammes.		Troy Grains.
Amsterdam wholesale	=	470401.	=	7264.88
retail	=	369003.3	=	5698.89
Austrian	=	400009.	=	6486.63
Paris	=	367129.4	=	5669.95
Bavarian since 1811	=	360000.	=	5559.85
before 1811	=	357712.5	=	5524.19
German, Prussian Russian, Danish	=	357663.9	=	5523.77
Swedish	=	356318.7	=	5502.99
Spanish	=	345027.6	=	5329.06
Venetian	=	302025.3	=	4664.48
Turin	=	307514.	=	4749.25
Florence	=	339515.	=	5243.48

Of these weights, all, except that of Paris, are divided into parts corresponding with those of the English Apothecaries' weight. In the Paris Apothecaries' weight, the gros or drachm contains 72 instead of 60 grains; but, as in the English, there are 8 drachms in the ounce, and 12 ounces in the pound.

APPROXIMATIVE MEASUREMENT.

For the sake of convenience, in the absence of proper instruments, we often make use of means of measurement, which, though not precise nor uniform, afford results sufficiently accurate for ordinary purposes. Of this kind are certain household implements, of a capacity approaching to uniformity, and corresponding to a certain extent with the regular standard measures. Custom has attached a fixed value to these implements, with which it is proper that the practitioner should be familiar; although their capacity, as they are now made, almost always somewhat exceeds that at which they were originally and still continue to be estimated.

A *tea-cup* is estimated to contain about	four fluidounces, or a gill.
A *wine-glass* - - - -	two fluidounces.
A *table-spoon* (cochlear magnum)	half a fluidounce.
A *tea-spoon* (cochlear parvum)	a fluidrachm.

Small quantities of liquid medicines are often estimated by *drops*, each of which is usually considered as equivalent to a minim, or the sixtieth part of a fluidrachm. The drop of water and of watery fluids is, on an average, about this size; but the same is by no means the case with all medicinal liquids; and the drop even of the same fluid varies exceedingly in bulk, according to the circumstances under which it is formed. This is, therefore, a very uncertain mode of estimating the quantity of liquids, and should be entirely superseded in the shops, where minim measures may be had.

The results stated in the following table were obtained by Mr. E. Durand, of Philadelphia. (See *Journ. of the Philadelphia College of Pharmacy*, i. 169.) They may be relied on as accurate; but should be considered as indicating only the relative number of drops afforded by the several liquids mentioned; for, under other circumstances than those of Mr. Durand's experiments, entirely different results might be obtained as relates to each liquid. The preparations experimented with were those of the first edition of the U.S. Pharmacopœia.

Table, exhibiting the Number of Drops of Different Liquids equivalent to a Fluidrachm.

	Drops.		Drops.
Acid Acetic (crystallizable)	120	Tincture of Assafetida, of Foxglove, of Guaiac, of Opium,	120

nitrous	$N+4O$	46.15

---

[*] This table includes the equivalents of all the simple bodies, although several of them are not used in medicine. It also embraces a few compounds which are not used in pharmacy, but which are inserted on account of their general importance. The numbers are derived from the fifth edition of Turner's Chemistry, and corrected by those contained in the second edition of Berzelius's *Théorie des Proportions Chimiques*, published at Paris in 1835.

[†] By modern chemists, the simple bodies are designated by letters, called *symbols.* The initial letter of the name is the symbol, whenever it is distinctive; but when several simple bodies have names beginning with the same letter, the plan adopted is to represent one of them by the initial letter, and the rest by the initial letter, with some other associated with it. Thus C stands for carbon, Cd for cadmium, Ca for calcium, Ce for cerium, Cl for chlorine, Cr for chromium, Co for cobalt, Cu for copper, &c. The use of these symbols saves time and space in designating the composition of compounds. Where a single equivalent is intended to be designated, the symbol of the body is simply given; but where several equivalents are to be represented, the symbol is preceded by a figure, indicating the number. Thus C means one equivalent of carbon; 2C, two equivalents; and so on. The group of letters and figures, thus used to denote the composition of any body, is called the *formula* of such body. In all cases, the constitution of compounds, however complex, may be expressed by *formulæ;* but in the above table this mode of notation is adopted only for the less complex compounds. The symbols used are those employed by Berzelius, and should not be varied from, for fear of destroying their usefulness by creating confusion.

V. CORRESPONDENCE BETWEEN DIFFERENT THERMOMETERS.

In *Fahrenheit's* thermometer, which is universally employed in this country and Great Britain, the freezing point of water is placed at 32°, and the boiling point at 212°, and the number of intervening degrees is 180.

The *Centigrade* thermometer, which has long been used in Sweden, under the name of Celsius's thermometer, and is now most generally employed on the continent of Europe, marks the freezing point *zero*, and the boiling point 100°.

In *Reaumur's* thermometer, used in France before the revolution, the freezing point is at zero, and the boiling point at 80°.

In *De Lisle's* thermometer, used in Russia, the graduation begins at the boiling point, which is marked *zero*, while the freezing point is placed at 150°.

From the above statement it is evident that 180 degrees of Fahrenheit are equal to 100° of the centigrade, 80° of Reaumur, and 150° of De Lisle, or 1 degree of the first is equal to $\frac{5}{9}$ of a degree of the second, $\frac{4}{9}$ of a degree of the third, and $\frac{5}{6}$ of a degree of the last. It is easy, therefore, to convert the degrees of one into the equivalent number of degrees of the other; but in ascertaining the corresponding points upon the different scales, it is necessary to take into consideration their different modes of graduation. Thus, as the zero of Fahrenheit is 32° below the point at which that of the centigrade and of Reaumur is placed, this number must be taken into account in the calculation. The following propositions will embrace all the cases which can arise in relation to the three last mentioned thermometers. That of De Lisle is seldom or never referred to in works which are read in this country.

1. If any degree on the *centigrade* scale, either above or below zero, be multiplied by 9 and divided by 5, or if any degree of *Reaumur* above or below zero be multiplied by 9 and divided by 4, the quotient will, in either case, be the number of degrees above or below 32° or the freezing point of *Fahrenheit.*

2. The number of degrees between any point of *Fahrenheit's* scale and 32°, if multiplied by 5 and divided by 9, will give the corresponding point on the *centigrade;* if multiplied by 4 and divided by 9, will give the corresponding point on the scale of *Reaumur.*

3. Any degree of the *centigrade* multiplied by 4 and divided by 5, will give the corresponding degree of *Reaumur;* and conversely, any degree of *Reaumur* multiplied by 5 and divided by 4, will give the corresponding degree of the *centigrade.*

VI. TABLE,

SHOWING THE SPECIFIC GRAVITY CORRESPONDING WITH THE SEVERAL DEGREES OF BAUME'S AND BECK'S HYDROMETERS.

Baumé's hydrometer is usually employed in France. In this instrument, the sp. gr. of distilled water is assumed as the zero of the descending scale, in relation to fluids heavier than itself, while it is assumed as 10 on the ascending scale, in relation to lighter fluids. In the Pharmacopœia Batava, a modification of the instrument has been adopted, in which the sp. gr. of distilled water has been assumed as the zero of both scales. This modification has also been adopted by the authors of the French Codex, and the sp. gr. corresponding to the several degrees of this scale is given below. Beck's hydrometer is used in Germany.

For Liquids lighter than Water.

Zinc 681
Zinc, acetate of 1034
Zinc, carbonate of 683
Zinc, cyanuret of 1070
Zinc, flowers of 1037
Zinc, impure oxide of 683
Zinc, iodide of 1080
Zinc, oxide of 1036
Zinc, preparations of 1034
Zinc, prepared carbonate of 1035
Zinc, silicate of 683
Zinc, suboxide of 1037
Zinc, sulphate of 1038
Zinc, superoxide of 1037
Zinc, table of the preparations of 682
Zinci acetas 1034
Zinci acetatis tinctura 1035
Zinci carbonas 683
Zinci carbonas impurum 683
Zinci carbonas impurum præparatum 1035
Zinci carbonas præparatus 1035
Zinci iodidum 1080
Zinci oxidum 1036
Zinci sulphas 1038
Zincum 681
Zingiber 684
Zingiber cassumuniar 1111
Zingiber officinale 684
Zingiber zerumbet 1111
Ziziphus jujuba 1111
Ziziphus lotus 1111
Ziziphus vulgaris 1111
Zumic acid 438
Zymome 657
